About this document

This topic collection contains sections on the system files, special files, header files, and directories that are provided with the operating system and optional program products. File formats required for certain files that are generated by the system or by an optional program are also presented in this topic collection.

Highlighting

The following highlighting conventions are used in this document:

| | |
|------------------|--|
| Bold | Identifies commands, subroutines, keywords, files, structures, directories, and other items whose names are predefined by the system. Bold highlighting also identifies graphical objects, such as buttons, labels, and icons that you select. |
| <i>Italics</i> | Identifies parameters for actual names or values that you supply. |
| Monospace | Identifies examples of specific data values, examples of text similar to what you might see displayed, examples of portions of program code similar to what you might write as a programmer, messages from the system, or text that you must type. |

Case sensitivity in AIX

Everything in the AIX® operating system is case sensitive, which means that it distinguishes between uppercase and lowercase letters. For example, you can use the **ls** command to list files. If you type **LS**, the system responds that the command is not found. Likewise, **FILEA**, **FiLea**, and **filea** are three distinct file names, even if they reside in the same directory. To avoid causing undesirable actions to be performed, always ensure that you use the correct case.

ISO 9000

ISO 9000 registered quality systems were used in the development and manufacturing of this product.

Files Reference

This topic collection contains sections on the system files, special files, header files, and directories that are provided with the operating system and optional program products. File formats required for certain files that are generated by the system or by an optional program are also presented this topic collection.

The AIX operating system is designed to support The Open Group's Single UNIX Specification Version 3 (UNIX 03) for portability of operating systems based on the UNIX operating system. Many new interfaces, and some current ones, have been added or enhanced to meet this specification. To determine the correct way to develop a UNIX 03 portable application, see The Open Group's UNIX 03 specification on The UNIX System website (<http://www.unix.org>).

What's new in Files Reference

Read about new or significantly changed information for the File Reference topic collection.

How to see what's new or changed

In this PDF file, you might see revision bars (|) in the left margin, which identify new and changed information.

June 2017

The following information is a summary of the updates made to this topic collection:

- Added description about the `pr_syset` array in the “/proc File” on page 229 topic.

January 2017

The following information is a summary of the updates made to this topic collection:

- Added description about the `authbasedn`, `rolebasedn`, `privcmdbasedn`, `privfilebasedn`, `domainbasedn`, and `domobjbasedn` fields in the “ldap.cfg File Format” on page 486 topic.

October 2016

The following information is a summary of the updates made to this topic collection:

- Updated the `perf_disk_data_t` structure information in the “libperfstat.h File” on page 897 topic.

March 2015

The following information is a summary of the updates made to this topic collection:

- Updated the **resolv.conf File Format for TCP/IP** topic.

System Files

The files in this section are system files. These files are created and maintained by the operating system and are necessary for the system to perform its many functions. System files are used by many commands and subroutines to perform operations. These files can only be changed by a user with root authority.

A file is a collection of data that can be read from or written to. A file can be a program you create, text you write, data you acquire, or a device you use. Commands, printers, terminals, and application

programs are all stored in files. This allows users to access diverse elements of the system in a uniform way and gives the operating system great flexibility. No format is implied when a file is created.

Files are used for all input and output (I/O) of information in this operating system. This standardizes access to both software and hardware. Input occurs when the content of a file is modified or written to. Output occurs when the content of one file is read or transferred to another file. For example, to create a hardcopy printout of a text file, the system reads the information from the text file and writes the data to the file representing the printer.

Collections of files are stored in directories. These collections of files are often related to each other, and storing them in a structure of directories keeps them organized.

There are many ways to create, use, and manipulate files. Files in *Operating system and device management* introduces the commands that control files.

Types of Files

There are three basic types of files:

| File Type | Description |
|-----------|---|
| regular | Stores data (text, binary, and executable). |
| directory | Contains information used to access other files. |
| special | Defines a FIFO (first-in, first-out) file or a physical device. |

All file types recognized by the system fall into one of these categories. However, the operating system uses many variations of these basic types.

Regular files are the most common. When a word processing program is used to create a document, both the program and the document are contained in regular files.

Regular files contain either text or binary information. Text files are readable by the user. Binary files are readable by the computer. Binary files can be executable files that instruct the system to accomplish a job. Commands, shell scripts, and other programs are stored in executable files.

Directories contain information the system needs to access all types of files, but they do not contain the actual file data. As a result, directories occupy less space than a regular file and give the file-system structure flexibility and depth. Each directory entry represents either a file or subdirectory and contains the name of a file and the file's i-node (index node reference) number. The i-node number represents the unique i-node that describes the location of the data associated with the file. Directories are created and controlled by a separate set of commands.

Special files define devices for the system or temporary files created by processes. There are three basic types of special files: FIFO (first-in, first-out), block, and character. FIFO files are also called pipes. Pipes are created by one process to temporarily allow communication with another process. These files cease to exist when the first process finishes. Block and character files define devices.

Every file has a set of permissions (called access modes) that determine who can read, modify, or execute the file. To learn more about file access modes, see File ownership and user groups in *Operating system and device management*.

File-Naming Conventions

The name of each file must be unique within the directory where it is stored. This insures that the file also has a unique path name in the file system. File-naming guidelines are:

- A file name can be up to 255 characters long and can contain letters, numbers, and underscores.

- The operating system is case-sensitive which means it distinguishes between uppercase and lowercase letters in file names. Therefore, FILEA, FiLea, and filea are three distinct file names, even if they reside in the same directory.
- File names should be as descriptive as possible.
- Directories follow the same naming conventions as files.
- Certain characters have special meaning to the operating system, and should be avoided when naming files. These characters include the following:
/ \ " ' * ; - ? [] () ~ ! \$ { } < > # @ & |
- A file name is hidden from a normal directory listing if it begins with a . (dot). When the **ls** command is entered with the **-a** flag, the hidden files are listed along with regular files and directories.

The path name of a file consists of the name of every directory that precedes it in the file tree structure. Only the final component of a path name can contain the name of a regular file. All other components in a path name must be directories. Path names can be absolute or relative. See *File path names* in *Operating system and device management* to learn more about the complete name of a file within the file system.

Files

Files, Directories, and File Systems for Programmers

access_lists File

Purpose

Configures access control lists for the iSCSI target driver.

Description

The **access_lists** file is used to configure access control lists for the iSCSI target driver. You can use comments in the **access_lists** file. The comment character is "#", and must be the first character on the line.

This file contains one entry per target. Each entry has the following format:

target_name|lun_name iSCSI_name,iSCSI_name,...

target_name

The target ODM name on which access control is applied.

lun_name

The logical unit number (LUN) ODM name on which access control is applied.

iSCSI_name

The list of iSCSI names (iqn or eui format) of initiators that can access this target or LUN.

You can use two default keywords in this file:

- | | |
|------------|---|
| all | Used for the target_name or lun_name field. It indicates that the Access Control List is the same for all targets and LUNs on the server. An entry containing all overrides other entries. |
| any | Used for the iSCSI_name field. It indicates that one target or LUN is visible by any initiator connecting to the server. |

You can use the line continuation character backslash (\) to make each entry easier to read.

Attention: If an access list grants an initiator the access to a LUN, the access list must also explicitly grant the access to the target that owns the LUN.

|--------------------------|----------------------------------|
| /etc/tmisci/access_lists | Configures Access Control Lists. |

acct.cfg File

Purpose

The **acct.cfg** file consists of CA stanzas and LDAP stanzas. The CA stanzas contain private CA information not suitable for the publicly readable **ca.cfg** file. LDAP stanzas contain LDAP information such as LDAP administrative names and passwords.

Description

For every CA stanza in the **ca.cfg** file, the **acct.cfg** file should contain an equivalently named CA stanza, and all CA stanzas must be uniquely named. On the other hand, all LDAP stanzas are named **ldap**. For this reason, a CA stanza cannot be named **ldap**. Also, no stanza can be named **default**. An LDAP stanza must exist and at least one CA stanza, named **local** must exist.

Examples

```
*****
* CA Stanzas:
*
* carefnum      Specifies the CA's reference number used while communicating
*                  with the CA through CMP. This value must be the same value as
*                  the one that is specified while configuring the CA. (Required)
*
* capasswd      Specifies the CA's password used while communicating with
*                  the CA. The length of the password must be at least 12
*                  characters long. This value must be the same value as the one
*                  that is specified while configuring the CA.(Required)
*
* rvrefnum      Specifies the revocation reference number used for revoking
*                  a certificate
*
* rvpasswd      Specifies the revocation password used for CMP. The length of
*                  the password must be at least 12 character long.
*
* keylabel      Defines the name of the key label in the trusted keystore.
*                  (Required)
*
* keypasswd      Defines the password of the trusted keystore. (Required)
*

* ldap Stanzas:
*
* ldappkiadmin   Specifies the PKI LDAP administrator account name.
*
* ldappkiadmpwd  Specifies the PKI LDAP administrator account password.
*
* ldapservers    Specifies the LDAP server machine name or IP address.
*
* ldapsuffix     Specifies the LDAP DN suffix for the root of the LDAP branch
*                  where the PKI data resides.
*
local:
  carefnum = 12345678
  capasswd = password1234
  rvrefnum = 9999997
  rvpasswd = password
  keylabel = "Trusted Key"
```

```

keypasswd = somepassword

ldap:
  ldapkiadmin = "cn=admin"
  ldapkiadmpwd = password
  ldapservers = myserver.mydomain.com
  ldapsuffix = "ou=cert,cn=aixsecdb"

```

certcreate command

certrevoke command

admin File

Purpose

Describes the format of an installation defaults file.

Description

admin is a generic name for an ASCII file that defines default installation actions by assigning values to installation parameters. For example, it allows administrators to define how to proceed when the package being installed already exists on the system.

/var/sadm/install/admin/default is the default **admin** file delivered with your system. The default file is not writable, so to assign values different from this file, create a new **admin** file. There are no naming restrictions for **admin** files. Name the file when installing a package with the **-a** flag of the **pkgadd** command. If the **-a** flag is not used, the default **admin** file is used.

Each entry in the **admin** file is a line that establishes the value of a parameter in the following form:

param=value

Eleven parameters can be defined in an **admin** file. A file is not required to assign values to all eleven parameters. If a value is not assigned, **pkgadd** asks the installer how to proceed.

The eleven parameters and their possible values are shown below except as noted. They may be specified in any order. Any of these parameters can be assigned the value **ask**, which means that, if the situation occurs, the installer is notified and asked to supply instructions at that time.

| Parameter | Description |
|-----------------|---|
| basedir | Indicates the base directory where relocatable packages are to be installed. The value may contain \$PKGINST to indicate a base directory that is to be a function of the package instance. |
| mail | Defines a list of users to whom mail should be sent following installation of a package. If the list is empty or if the parameter is not present in the admin file, the default value of root is used. The ask value cannot be used with this parameter. |
| runlevel | Indicates resolution if the run level (system state) is not correct for the installation or removal of a package. Options are: nocheck Do not check for run level (system state). quit Abort installation if run level (system state) is not met. |

| Parameter | Description |
|-----------------|--|
| conflict | Specifies what to do if an installation expects to overwrite a previously installed file, thus creating a conflict between packages. Options are: nocheck Do not check for conflict; files in conflict are overwritten. quit Abort installation if conflict is detected. |
| nochange | Override installation of conflicting files; conflicting files are not installed. |
| setuid | Checks for executables that have setuid or setgid bits enabled after installation. Options are: nocheck Do not check for setuid executables. quit Abort installation if setuid processes are detected. |
| nochange | Override installation of setuid processes; processes are installed without setuid bits enabled. |
| action | Determines if action scripts provided by package developers contain possible security impact. Options are: nocheck Ignore security impact of action scripts. quit Abort installation if action scripts may have a negative security impact. |
| partial | Checks to see if a version of the package is already partially installed on the system. Options are: nocheck Do not check for a partially installed package. quit Abort installation if a partially installed package exists. |
| idepend | Controls resolution if other packages depend on the one to be installed. Options are: nocheck Do not check package dependencies. quit Abort installation if package dependencies are not met. |
| rdepend | Controls resolution if other packages depend on the one to be removed. Options are: nocheck Do not check package dependencies. quit Abort removal if package dependencies are not met. |
| space | Controls resolution if disk space requirements for package are not met. Options are: nocheck Do not check space requirements (installation fails if it runs out of space). quit Abort installation if space requirements are not met. |

The value **ask** cannot be defined in an **admin** file that is used for non-interactive installation (since by definition, there is no installer interaction). Doing so causes installation to fail when input is needed.

“pkginfo File” on page 217

Related information:

pkgadd command

aliases File for Mail

Purpose

Contains alias definitions for the **sendmail** command.

Description

The **/etc/mail/aliases** file contains the required aliases for the **sendmail** command. Do not change these defaults, as they are required by the system. The file is formatted as a series of lines in the form:

name: name_1, name_2, name_3,...

The **name:** is the name of the alias, and the **name_n** are the aliases for that name. Lines beginning with white space are continuation lines. Lines beginning with a # (pound sign) are comments.

Aliasing occurs only on local names. System-wide aliases are used to redirect mail. For example, if you receive mail at three different systems, you can use the **/etc/mail/aliases** file to redirect your mail to one of the systems. As an individual user, you can also specify aliases in your **.mailrc** file.

Aliases can be defined to send mail to a distribution list. For example, you can send mail to all of the members of a project by sending mail to a single name.

The sender of a message is not included when the **sendmail** command expands an alias address. For example, if amy sends a message to alias D998 and she is defined as a member of that alias, the **sendmail** command does not send a copy of the message to amy.

The **/etc/mail/aliases** file is a raw data file. The **sendmail** command uses a database version of this file. You must build a new alias database by running the **sendmail -bi** command or the **newaliases** command before any changes made to the **/etc/mail/aliases** file become effective.

As long as you do not rebuild the **aliases** database, **sendmail** will continue to read it in its old DBM format. This consists of two files: **/etc/mail/aliases.dir** and **/etc/mail/aliases.pag**. However, the moment you rebuild the **aliases** database, **sendmail** will change this format to Berkeley DB. This file will be stored in **/etc/mail/aliases.db**.

Note: Upper case characters on the left hand side of the alias are converted to lowercase before being stored in the **aliases** database. In the following example, mail sent to the **testalias** user alias fails, since TEST is converted to test when the second line is stored.

```
TEST: user@machine
testalias: TEST
```

To preserve uppercase in user names and alias names, add the **u** flag to the local mailer description in the **/etc/mail/sendmail.cf** file. Thus, in the example above, mail to the **testalias** user alias would succeed.

Files

| Item | Description |
|--------------------------------------|--|
| /etc/mail/aliases | Contains systemwide aliases. |
| /etc/mail/aliasesDB directory | Contains the binary files created by the newaliases command, including the DB.dir and DB.pag files. |
| /etc/mail/aliases.db | Contains the binary file storing the aliases database in Berkeley DB format, created by the newaliases command |

Alias database building

audit File for BNU

Purpose

Contains debug messages from the **uucico** daemon.

Description

The **/var/spool/uucp/.Admin/audit** file contains debug messages from the **uucico** daemon when it is invoked as a result of a call from another system. If the **uucico** daemon is invoked from the local system, the debug messages are sent to either the **/var/spool/uucp/.Admin/errors** file or to standard output.

Files

| Item | Description |
|-------------------------------|---|
| /var/spool/uucp/.Admin/audit | Specifies the path of the audit file. |
| /var/spool/uucp/.Admin/errors | Contains a record of uucico daemon errors. |

Related information:

uudemon.cleanu command
cron command
BNU log files
BNU File and Directory Structure

/etc/security/authorizations File

Purpose

Contains the list of valid, user-defined authorizations.

Description

The **/etc/security/authorizations** file stores the list of valid, user-defined authorizations available on a system. An authorization administrator can modify user-defined authorizations. System-defined authorizations do not appear in this file. You can add new authorizations to this file using the **mkauth** command and modify authorizations using the **chauth** command.

The **/etc/security/authorizations** file is an ASCII file that uses a stanza for each user-defined authorization. Each stanza is identified by the authorization name followed by a colon (:). You can list authorization attributes individually as *Attribute=Value* pairs on subsequent lines. Each attribute pair ends with a newline character, as does each stanza. For an example of a stanza, see “Examples” on page 9.

When the system is operating in Enhanced RBAC Mode, changes that you make to the authorizations file do not impact security considerations until you send the entire authorization database to the Kernel Security Tables using the **setkst** command, or until the system is rebooted.

Modifying and listing entries in the authorizations file

Do not directly edit the **/etc/security/authorizations** file. Use the following commands and subroutines to manipulate the authorization database:

mkauth

Adds new authorizations to the **/etc/security/authorizations** file.

chauth

Changes user-defined authorization attributes.

lsauth

Displays authorizations that are defined in this file and system-defined authorizations.

rmauth

Removes entries from this file.

To write programs that affect entries in the **/etc/security/authorizations** file, use one or more of the following subroutines:

- **getauthattr**
- **getauthattrs**
- **putauthattr**
- **putauthattrs**

Attributes

A stanza in this file contains one or more of the following attributes:

| Attribute | Description |
|----------------|--|
| id | Specifies the unique numeric ID of the authorization. This is a required attribute and is used internally for security decisions. Do not modify this ID after creating the authorization. The value is a unique decimal integer greater than 10000. Values below 10000 are reserved for system-defined authorizations. |
| dfltmsg | Specifies the default authorization-description text if message catalogs are not in use. The value is a character string. |
| msgcat | Specifies the file name of the message catalog that contains the one-line description of the authorization. The value is a character string. |
| msgset | Specifies the message set that contains the authorization description in the message catalog. The value is a decimal integer. |
| msgnum | Specifies the message ID that contains the authorization description in the message catalog. The value is a decimal integer. |

Security

The root user and the security group own this file. This files grants read and write access to the root user. Access for other users and groups depends on the security policy for the system.

Examples

The following example for the custom authorization displays a typical stanza in the file:

custom:

```
    id = 11000
    dfltmsg = "Custom Authorization"
    msgcat = "custom_auths.cat"
    msgset = 1
    msgnum = 5
```

Role Based Access Control (RBAC)

autosecrets File

Purpose

Configures iSCSI target passwords.

Description

The **autosecrets** file is used to configure iSCSI target passwords. You can use comments in the **autosecrets** file. The comment character is "#", and must be the first character on the line.

This file contains one entry per target. Each entry has the following format:

target_name chap_name chap_secret

target_name

The ODM name of the target.

chap_name

The CHAP name associated with this password. The iSCSI initiator identifies itself by sending this name to the iSCSI target during the authentication process.

chap_secret

The password, enclosed in double quotation marks.

You can use the line continuation character backslash (\) to make each entry easier to read.

Examples

If the target ODM name is target0, the CHAP name is iqn.com.ibm-K167-42.fc1a, and the **chap_name** is secret.fc1a, the entry looks like the following example:

```
target0 iqn.com.ibm-K167-42.fc1a "secret.fc1a"
```

The following example has the same **target**, **chap_name**, and **chap_secret**, but with a line continuation character.

```
target0 iqn.com.ibm-K167-42.fc1a \
"secret.fc1a"
```

Files

| Item | Description |
|--------------------------|------------------------------------|
| /etc/tmiscsi/autosecrets | Configures iSCSI target passwords. |

backup File

Purpose

Copies the file system onto temporary storage media.

Description

A backup of the file system provides protection against substantial data loss due to accidents or error. The **backup** command writes file system backups in the **backup** file format, and conversely, the **restore** command reads file system backups. The backup file contains several different types of header records along with the data in each file that is backed up.

Header Records

The different types of header records for by-name backups are:

| Header Record | Description |
|---------------|---|
| FS_VOLUME | Exists on every volume and holds the volume label. |
| FS_NAME_X | Holds a description of a file backed up by name. |
| FS_END | Indicates the end of the backup. This header appears at the end of the last volume. |

The different types of header records for by-inode and name backups are:

| Header Record | Description |
|----------------------|---|
| TS_TAPE | Exists on every volume and holds the volume label. |
| TS_BITS | Describes the directory structure. |
| TS_CLRI | Describes the unused i-node numbers on the backup system. |
| TS_INODE | Describes the file. |
| TS_ADDR | Indicates a continuation of the preceding file. |
| TS_END | Indicates the end of the backup. |

The descriptions of the fields of the header structure for by-inode backups are:

| Header Record | Description |
|----------------------|---|
| c_type | The header type. |
| c_date | The current dump date. |
| c_ddate | The file system dump date. |
| c_volume | The volume number. |
| c_tapea | The number of the current header record. |
| c_inumber | The i-node number on this record. |
| c_magic | The magic number. |
| c_checksum | The value that would make the record sum to the CHECKSUM value. |
| bsd_c_dinode | A copy of the BSD i-node as it appears on the BSD file system. |
| c_count | The number of characters in the c_addr field. |
| c_addr | A character array that describes the blocks being dumped for the file. |
| xix_flag | Set to the XIX_MAGIC value if doing the backup of a file system. |
| xix_dinode | The real di-node from the file system. |

Each volume except the last ends with a tape mark (read as an end of file). The last volume ends with a **TS_END** record and then the tape mark.

By-Name Format

The format of a by-name backup is:

FS_VOLUME

FS_NAME_X (before each file)

File Data

FS_END

By-Inode Format

The format of a by-inode backup follows:

TS_VOLUME

TS_BITS

TS_CLRI

TS_INODE

TS_END

A detailed description of the by-inode header file follows:

```

union u_spcl {
    char dummy[TP_BSIZE];
    struct s_spcl {
        int      c_type;           /* 4 */
        time_t   c_date;          /* 8 */
        time_t   c_ddate;         /* 12 */
        int      c_volume;        /* 16 */
        daddr_t  c_tapea;         /* 20 */
        ino_t    c_inumber;       /* 24 */
        int      c_magic;         /* 28 */
        int      c_checksum;       /* 32 */
        struct   bsd_dinode  bsd_c_dinode; /* 160 */
        int      c_count;          /* 164 */
        char    c_addr[TP_NINDIR]; /* 676 */
        int      xix_flag;         /* 680 */
        struct   dinode     xix_dinode;  /* 800 */
    } s_spcl;
} u_spcl;

```

Constants

Constants used to distinguish these different types of headers and define other variables are:

```

#define OSF_MAGIC      (int)60011
#define NFS_MAGIC      (int)60012      /* New File System Magic */
#define XIX_MAGIC      (int)60013      /* Magic number for v3 */
#define BYNAME_MAGIC  (int)60011      /* 2.x magic number */
#define PACKED_MAGIC   (int)60012      /* 2.x magic number for */
                                         /* Huffman packed format */
#define CHECKSUM       (int)84446      /* checksum magic number */
#define TP_BSIZE        1024         /* tape block size */
#define TP_NINDIR      (TP_BSIZE/2)   /* num of indirect pointers */
                                         /* in an inode record */
#define FS_VOLUME       0            /* denotes a volume header */
#define FS_END          7            /* denotes an end of backup */
#define FS_NAME_X       10           /* denotes file header */
#define SIZSTR          16           /* string size in vol header*/
#define DUMNAME         4            /* dummy name length for */
                                         /* FS_NAME_X */
#define FXLEN           80           /* length of file index */

```

Related information:

backup command

pack command

File systems

bincmds File

Purpose

Contains the shell commands that process audit bin data.

Description

The */etc/security/audit/bincmds* file is an ASCII template file that contains the backend commands that process audit binfile records. The path name of this file is defined in the **bin** stanza of the */etc/security/audit/config* file.

This file contains command lines each composed of one or more commands with input and output that can be piped together or redirected. Although the commands usually are one or more of the audit system commands (the **auditcat** command, the **auditpr** command, the **auditselect** command), this is not a requirement.

As each bin file is filled by the kernel, the **auditbin** daemon invokes each command to process the bin records, substituting the names of the current bin file and the audit trail file for any **\$trail** and **\$bin** strings in the commands. Upon startup, if the **auditbin** daemon detects that the bin files require a recovery procedure, the command will prepend a **-r** to the bin file's name in **\$bin**.

Note: The commands are executed by the trusted shell (TSH) when on the trusted path. This means that the path names in the commands must be absolute, and that environment variable substitution may be limited. See the discussion of the **tsh** command for more information.

Security

Access Control: This file should grant read (r) access to the root user and members of the audit group and grant write (w) access only to the root user.

Examples

1. To compress audit bin records and append them to the system audit trail file, include the following line in the **/etc/security/audit/bincmds** file:

```
/usr/sbin/auditcat -p -o $trail $bin
```

When the command runs, the names of the current bin file and the system audit-trail file are substituted for the **\$bin** and **\$trail** strings. Records are compressed and appended to the **/audit/trail** file.

2. To select the audit events from each bin file that are unsuccessful because of authentication or privilege reasons and append the events to the **/audit/trail.violations** file, you must include the following line in the **/etc/security/audit/bincmds** file:

```
/usr/sbin/auditselect -e "result == FAIL_AUTH || \  
result == FAIL_PRIV" $bin >> /audit/trail.violations
```

3. To create a hard-copy audit log of all local user authentication audit events, include the following line in the **/etc/security/audit/bincmds** file:

```
/usr/sbin/auditselect -e "event == USER_Login || \  
event == USER_SU" $bin | \  
/usr/sbin/auditpr -t2 -v >/dev/lpr3
```

Adjust the printer name to fit your requirements.

Note: The **auditselect** command does not support the **-r** flag (recovery). To process the **\$bin** string, use the **auditcat** command before using the **auditselect** command.

Files

| Item | Description |
|---------------------------------------|--|
| /etc/security/audit/bincmds | Specifies the path to the file. |
| /etc/security/audit/config | Contains audit-system configuration information. |
| /etc/security/audit/events | Contains the audit events of the system. |
| /etc/security/audit/objects | Contains audit events for audited objects (files). |
| /etc/security/audit/streamcmds | Contains auditstream commands. |

BOOTP Relay Agent Configuration File

Purpose

Default configuration information for the BOOTP (boot protocol) relay agent program (dhcprd).

Description

The dhcprd configuration file contains entries for logging information and servers to receive BOOTP packets.

This file is part of TCP/IP in Network Support Facilities in Base Operating System (BOS) Runtime.

Following are the formats for the data in the configuration file.

| Format | Meaning |
|-----------------------|---|
| # Comment line | The # character means that there is a comment from that point to the end of the line. |
| numLogFile n | Specifies the number of log files. If 0 is specified, no log file will be maintained, and no log message is displayed anywhere. <i>n</i> is the maximum number of log files maintained as the size of the most recent log file reaches its maximum size and a new log file is created. |
| logFileSize n | Maximum size of a log file. When the size of the most recent log file reaches this value, it is renamed and a new log file is created. <i>n</i> is measured in kilobytes(KB). |
| logFileName filename | Name and path of the most recent log file. Less recent log files have the number 1 to (n - 1) appended to their names; the larger the number, the older the file. |
| logItem <option name> | One item that will be logged. Multiple of these lines are allowed. This allows for the specified logging level to be turned on. The following are option names: SYSERR System error, at the interface to the platform OBJERR Object error, in between objects in the process PROTERR Protocol error, between client and server WARNING Warning, worth attention from the user EVENT Event occurred to the process ACTION Action taken by the process INFO Information that might be useful ACNTING Who was served, and when TRACE Code flow, for debugging. The address of a server to receive the DHCP or BOOTP packet. Multiple servers may be specified, and all will receive the packet. |
| server <ip address> | |

Example

The following example sets the logging parameters and configures two servers to receive BOOTP and DHCP packets. The servers are specified singly and with their ip addresses. The logging statements below tell the daemon to use at most four logfiles, rotate the log files after their size is 100 kilobytes of data, and place the files in the local directory and use **dhcpsd.log** as the base name. On rotation, the old file will be moved to **dhcpsd.log1**, and the daemon will start logging to an empty **dhcpsd.log**.

```
numLogFile 4
logFileSize 100
logFileName dhcpsd.log
logItem SYSERR
logItem OBJERR
logItem PROTERR
logItem WARNING
logItem EVENT
logItem ACTION
logItem INFO
logItem ACNTING
logItem TRACE
```

bootparams File for NFS

Purpose

Contains the list of client entries that diskless clients use for booting.

Description

The **/etc/bootparams** file for Network File System (NFS) contains a list of client entries that diskless clients use for booting. The first item of each entry is the name of the diskless client. Each entry should contain the following information:

- Name of client
- List of keys, names of servers, and path names

Items are separated by tab characters.

Examples

The following is an example of a **/etc/bootparams** file:

```
myclient root=myserver:/nfsroot/myclient \
    swap=myserver:/nfsswar/myclient \
    dump=myserver:/nfsdump/myclient
```

Files

| Item | Description |
|-----------------|---|
| /etc/bootparams | Specifies the path of the bootparams file. |

Network File System Overview

ca.cfg File

Purpose

The **ca.cfg** file consists of CA stanzas. The CA stanzas contain public CA information used by the Certificate Authentication Services for generating certificate requests and certificate revocation requests.

Description

For every CA stanza in the **ca.cfg** file, the **acct.cfg** file should contain an equivalently named CA stanza. Each CA stanza name in the **ca.cfg** file must be unique. At least one stanza named **local** must exist. No stanza should be named **ldap** or **default**.

Examples

```
* Multiple components of the PKI implementation use this file for configuration
* information.
*
* algorithm      Defines the encryption algorithm used for CMP requests.
*                  Supported values are RSA and DSA. The default is RSA.
*
* crl            Specifies the CA's root certificate file.
*
* dn             Defines the default Distinguished Name value for newly
*                 created certificates. (Optional) Example:
*                 dn = "c=US, o=ZZZ Corp., ou=Sales OEM, sp=Texas, l=Austin"
*
* keysize         Defines the minimum number of bits required when generating
*                 an encryption/signing key. The default is 1024.
*
* program        Specifies the PKI service module file name.
*                 (Required)
*
* retries         Defines the number of retry attempts when contacting a CA.
*                 The default is 5.
*
* server          Defines the URL address of the CA server. Example:
*                 "cmp://9.53.149.39:1077".
*
* signinghash    Specifies the hash algorithm used to verify keys and to
*                 perform trusted certificate signing when validating users.
*                 Supported values are MD2, MD5, and SHA1. The default is MD5.
*
* trustedkey     Defines the keystore location containing the system-wide
*                 trusted signing key used to sign/verify user certificates.
*
* url            Defines the default subject alternate name URI value to be
*                 added to new certificates.
*
local:
  program = /usr/lib/security/pki/JSM
  trustedkey = file:/usr/lib/security/pki/trusted.p15
  server = "cmp://9.53.149.39:1077"
  crl = ldap://9.53.149.39/o=XYZ, c=us
  dn = "c=US, o=XYZ"
  url = "http://www.ibm.com/"
```

```
algorithm = RSA
keysize = 512
retries = 5
signinghash = MD5
```

certcreate command

cdromd.conf File Format

Purpose

Defines for the **cdromd** daemon the managed devices and supported file system types.

Description

The /etc/cdromd.conf is the configuration file for the **cdromd** daemon. This file enables you to specify the devices to manage and the file system types to handle.

If you change the /etc/cdromd.conf file, run **refresh -s cdromd** or **kill -1 CdromdPID** command to inform the daemon of the changes to its configuration file.

The **cdromd** daemon reads its configuration file only when it starts, when the **cdromd** daemon receives a SIGHUP signal, or when the SRC **refresh -s cdromd** command is entered.

An information line in the **cdromd** configuration file defines either a device to manage or a file system type to handle. Lines starting with the pound sign (#) are comment lines. Fields in information lines must be separated by spaces or tabs. A device information line starts with <device> keyword and is of the form:

```
device device_name mount_point
```

| Item | Description |
|-------------|--|
| device_name | Contains a valid device name, as printed by the lsdev command, such as: lsdev -Cc cdrom -F name |
| mount_point | Contains the path of the directory for the mount operation. It must begin with a / |

If there is no line in the configuration file beginning with the **device** keyword, all the CD-ROM and DVD devices available on the system will be managed by **cdromd**, and a media inserted in the **cd<x>** drive will be automatically mounted on **/cdrom/cd<x>** directory.

A file system type information line starts with the **fstype** keyword and is of the form:

```
fstype VfsName fs_options
```

| Item | Description |
|------------|--|
| VfsName | Contains the VFS type used with the -V flag of the mount command. Only cdrfs and udfs types can be used. |
| fs_options | Contains the comma separated list of options used with the -o flag of the mount command (see mount command man page). |

If there is no line beginning with the **fstype** keyword in the configuration file, the **mount** command will be called with one of the following options:

-V cdrfs -o ro

or

-V udfs -o ro

If you want the UDFS file system to be mounted in read/write mode by default, add the following line to the **cdromd.conf** file:

```
fstype      udfs      rw
```

Examples

The following example of **cdromd.conf** file is for a **cdromd** daemon that:

- Manages cdrom cd0 with inserted media mounted on **/mnt** with either **-V cdrfs -o ro** or **-V udfs -o ro** options.
- Manages cdrom cd1 with inserted media mounted on **/install** with either **-V cdrfs -o ro** or **-V udfs -o ro** options.

```
device      cd0      /mnt
device      cd1      /install
fstype     cdrfs     ro
fstype     udfs      ro
```

ClientHostName.info File

Purpose

Created by the Network Installation Management (NIM) software to deliver information to the boot environment of NIM client machines.

Note: In AIX Version 4, this is an internal file to the Network Installation Management software and should not be modified manually.

Description

The NIM software creates the *ClientHostName.info* file to deliver information to the boot environment of NIM client machines. The file resides in the **/tftpboot** directory on the server of the NIM Shared Product Object Tree (SPOT), with a format of *ClientHostName.info* where *ClientHostName* is the hostname of the client machine.

After the client machine performs a network boot, it retrieves a copy of the *ClientHostName.info* file from the boot server using **tftp**. The client machine then uses the contents of the *ClientHostName.info* file to define environment variables for further processing in the boot process.

The *ClientHostName.info* file is used to support network boot for the following NIM operations:

- Installing the Base Operating System onto standalone machines
- Initializing diskless/dataless machines
- Diagnostics boot

Some of the variables defined in the *ClientHostName.info* file are common to all operations while others are operation-specific.

The following variables may be defined in the *ClientHostName.info* file:

Note: These variables are managed by the **nim** command and should not be modified by other means.

| Variable | Description |
|----------------------------|---|
| NIM_NAME | Identifies the client machine in the NIM environment. |
| NIM_HOSTNAME | Identifies hostname of the client machine. |
| NIM_CONFIGURATION | Describes the configuration of the client's resource requirements. Possible values are standalone , diskless , and dataless . |
| NIM_MASTER_HOSTNAME | Identifies the hostname of the NIM master in the network. |
| NIM_MASTER_PORT | Specifies the port number on the NIM master that should be used for NIM communications. |
| RC_CONFIG | Specifies the file that defines the configuration procedures the client machine should follow as it boots. Possible values are rc.bos_inst , rc.dd_boot , and rc.diag . |
| NIM_BOSINST_RECOVER | Specifies the script that initializes the BOS installation environment for NIM. |
| SPOT | Specifies the location of the Shared Product Object Tree resource that will be used during the boot process. |
| ROOT | Specifies the location of the root filesystem that will be mounted by diskless/dataless machines. |
| DUMP | Specifies the location of the dump resource that will be mounted by diskless/dataless machines. |
| NIM_CUSTOM | Names the command to execute a NIM script during post-installation processing. |
| NIM_BOS_IMAGE | Specifies the image from which the Base Operating System will be installed. |
| NIM_BOS_FORMAT | Specifies the format of the image that will be used to install the Base Operating System. |
| NIM_HOSTS | Specifies the IP addresses and hostnames of the NIM machines that will participate in the operation. |
| NIM_MOUNTS | Specifies the filesystems that will be mounted during the operation. |
| ROUTES | Specifies the routes from the client machine to other networks in the NIM environment. The format of each value is a colon-separated list of the network IP address, the network subnet mask, and the IP address of the gateway to the network. |

Example

This example shows the contents of the file **/tftpboot/devon.austin.ibm.com.info** after a bos installation has been enabled via the following command:

```

nim -o bos_inst -a source=rte devon

export NIM_NAME=devon
export NIM_HOSTNAME=devon.austin.ibm.com
export NIM_CONFIGURATION=standalone
export NIM_MASTER_HOSTNAME=redfish.austin.ibm.com
export NIM_MASTER_PORT=1058
export RC_CONFIG=rc.bos_inst
export
NIM_BOSINST_RECOVER="/.../SPOT/usr/lpp/bos.sysmgt/nim/methods/
    c_bosinst_env -a
hostname=devon.austin.ibm.com"

```

```

export SPOT=redfish.austin.ibm.com:/spot/myspot/usr
export
NIM_CUSTOM="/../SPOT/usr/lpp/bos.sysmgmt/nim/methods/c_script -a
location=redfish.austin.ibm.com:/export/nim/scripts/devon.script"
export NIM_BOS_IMAGE=/SPOT/usr/sys/inst.images/bos
export NIM_BOS_FORMAT=rte
export NIM_HOSTS=" 129.35.134.9:devon.austin.ibm.com
9.3.84.202:redfish.austin.ibm.com "
export NIM_MOUNTS="
redfish.austin.ibm.com:/lppsource/imagedir:/SPOT/usr/sys/inst.images:dir "
export ROUTES=" 9.3.84.128:255.255.128:129.35.128.201 "

```

nim command

clsnmp.conf File

Purpose

Contents are used by the **clsnmp** command to identify a host on which an SNMP agent is running.

Description

The contents of the **clsnmp.conf** file used by the **clsnmp** command are as follows. Each entry identifies:

- a host on which an SNMP agent is running,
- the administrative model used to communicate with the host at that agent,
- and the security parameters to be used in the communication.

An entry in the **clsnmp.conf** file has the following syntax:

```
winSnmpName targetAgent admin secName password context secLevel authProto
authKey privProto privKey
```

where:

winSnmpName

An administrative name by which the winSNMP code used by **clsnmp** can locate an entry in this configuration file. This value is to be specified on the **-h** keyword for the **clsnmp** command. The valid value must be a character string of 1 to 32 characters. There is no default value.

targetAgent

Identification of the target SNMP agent. By default, the port at which the agent is to receive requests is 161. To specify a port other than 161, use the syntax of:

```
host:port_number (host colon port_number)
```

The attribute must have one of the following values:

- A host name of 1 to 80 characters.
- An IPv4 address that must be in the form of a.b.c.d , where a, b, c, and d are in the range of 0 through 255.
- An IPv6 address. If the port number is specified, it must be of a value that ranges from 1 through 65535.

admin Specifies the administrative model supported by the **targetAgent**. The following values are valid:

snmpv1

Indicates community based security with SNMPv1 message protocol data units.

snmpv2c

Indicates community based security with SNMPv2 message protocol data units.

snmpv3

Indicates user based security (USM) with SNMPv3 message protocol data units.

There is no default value.

secName

Specifies the security name of the principal using this configuration file entry. For user-based security, this is the **userName**. The user must be defined at the **targetAgent**. This field is ignored unless **snmpv3** is specified for the **admin** keyword. The valid value must be a user name of 1 to 32 characters. There is no default value.

password

Specifies the password to be used in generating the authentication and privacy keys for this user. If a password is specified, the values of the **authKey** and **privKey** fields will be ignored.

Note: the use of password instead of keys in this configuration file is not recommended, as storing passwords in this file is less secure than using keys.

This field is ignored unless **snmpv3** is specified for the **admin** keyword. The valid value must be a password of 8 to 64 characters. A '-' (dash) indicates the default. The default value is no password.

context

Specifies the SNMP **contextName** to be used at the target agent. Note, the **contextName** is needed only at agents that support multiple contexts. Otherwise, the only context supported is the null context, which is the default value of this keyword. The CS for OS/390® SNMP agent does not support multiple contexts. This field is ignored unless **snmpv3** is specified for the **admin** keyword. The valid value must be a **contextName** of 1 to 40 32 characters. A '-' (dash) indicates the default. The default value is the null context ("").

secLevel

Specifies the security level to be used in communicating with the target SNMP agent when this entry is used. This field is ingored unless **snmpv3** is specified for the **admin** keyword.

Note: Privacy will be supported on CS for OS/390 V2R7 only in a separately orderable FMID. It will not be supported in the base FMID.

These values are valid: **noAuthNoPriv** or **none** which indicates no authentication or privacy requested. **AuthNoPriv** or **auth** indicates authentication is requested, but privacy is not requested. **AuthPriv** or **priv** indicates both authentication and privacy are requested (only supported in the additional encryption product) . A '-' (dash) indicates the default. The default value is **none** (**noAuthNoPriv**).

authProto

Specifies the SNMP authentication protocol to be used in communicating with the target SNMP agent when this entry is used. This field is ignored unless **snmpv3** is specified for the **admin** keyword. The following values are valid:

HMAC-MD5

Indicates HMAC mode MD5.

HMAC-SHA

Indicates HMAC mode SHA.

A '-' (dash) indicates the default. The default value is no authentication.

authKey

Specifies the SNMP authentication key to be used in communicating with the target SNMP agent when this entry is used. This key must be the non-localized key. This field is ignored if the **password** keyword is used. This field is ignored unless **snmpv3** is specified for the **admin** keyword and a non-default value is specified for **authProto**. The following values are valid:

- A key of 16 bytes (32 hex digits) when authProto is HMAC-MD5
- A key of 20 bytes (40 hex digits) when authProto is HMAC-SHA

A '-' (dash) indicates the default. The default value is no key.

privProto

Specifies the SNMP privacy protocol to be used in communicating with the target SNMP agent when this entry is used.

Note: Privacy will be supported on CS for OS/390 V2R7 only in a separately orderable FMID. It will not be supported in the base FMID.

If privacy is not supported, this keyword will be ignored. This field is ignored unless **snmpv3** is specified for the **admin** keyword. The following values are valid:

- DES - for CBC-DES (only supported in the additional encryption product)

A '-' (dash) indicates the default. The default value is no privacy.

privKey

Specifies the SNMP privacy key to be used in communicating with the target SNMP agent when this entry is used. This key must be the non-localized key. This field is ignored if the **password** keyword is used. If privacy is not supported, this keyword will be ignored. The privacy and authentication keys are assumed to have been generated using the same authentication protocol (e.g., both with HMAC-MD5 or both with HMAC-SHA). This field is ignored unless **snmpv3** is specified for the **admin** keyword and a non-default value is specified for **privProto**. The following values are valid:

- A key of 16 bytes (32 hex digits) when authProto is HMAC-MD5
- A key of 20 bytes (40 hex digits) when authProto is HMAC-SHA

A '-' (dash) indicates the default. The default value is no key.

General Usage Rules

- All parameters for an entry must be contained on one line in the # configuration file.
- A "-" (dash) is used to indicate the default value for a keyword.
- Sequence numbers are not allowed on the statements.
- Comments may be included in the file beginning with a pound sign (#) in column 1.
- The **secName** and **password** parameters are case-sensitive.

As the **clsnmp** command supports both issuance of SNMP requests and receipt of SNMP traps, the entries in the **clsnmp.conf** file must be defined for both uses. Multiple entries for the same USM user are allowed within the file. This may be useful to define different security levels for the same user. If multiple entries for the same USM user are defined, be aware that only the first one in the file can be used for receiving notifications. If multiple entries for the same USM user are defined and the user will be used for receiving notifications, the definition with the highest (most stringent) **securityLevel** should be defined first. Doing so will allow the user to be used for any level of security equal to or lower (less stringent) than the **securityLevel** defined.

SNMP trap processing

Command (C.*) Files for BNU

Purpose

Contains file transfer directions for the **uucico** daemon.

Description

Command (C.*) files contain the directions that the Basic Networking Utilities (BNU) **uucico** daemon follows when transferring files. The full path name of a command file is a form of the following:

/var/spool/uucp/SystemName/C.SystemNameNxxxx

The *SystemName* variable indicates the name of the remote system. The *N* character represents the grade of the work. The *xxxx* notation is the four-digit hexadecimal transfer-sequence number; for example, *C.merlinC3119*.

The grade of the work specifies when the file is to be transmitted during a particular connection. The grade notation characteristics are:

- A single number (0-9) or letter (A-Z, a-z)
- Lower sequence characters cause the file to be transmitted earlier in the connection than do higher sequence characters. Sequence is established using ASCII order, beginning with 0 and ending with z.
- The number 0 is the highest grade (that is, the lowest character in the sequence), signifying the earliest transmittal; z is the lowest grade, specifying the latest transmittal.
- The default grade is N.

A command file consists of a single line that includes the following kinds of information in the following order:

1. An S (send) or R (receive) notation.

Note: A send command file is created by the **uucp** or **uuto** commands; a receive command file is created by the **uux** command.

2. The full path name of the source file being transferred. A receive command file does not include this entry.
3. The full path name of the destination file, or a path name preceded by *~user*, where *user* is a login name on the specified system. Here, the ~ (tilde) is shorthand for the name of the user's home directory.
4. The sender's login name.
5. A list of the options, if any, included with the **uucp**, **uuto**, or **uux** command.
6. The name of the data file associated with the command file in the spooling directory. This field must contain an entry. If one of the data-transfer commands (such as the **uucp** command with the default **-c** flag) does not create a data file, the BNU program instead creates a placeholder with the name **D.0** for send files or the name **dummy** for receive files.
7. The source file permissions code, specified as a three-digit octal number (for example, 777).
8. The login name of the user on the remote system who is to be notified when the transfer is complete.

Examples

The following are two examples of using the command (C.*) files.

Two Send Command Files

1. The send command file /var/spool/uucp/venus/C.heraN1133, created with the **uucp** command, contains the following fields:
`S /home/amy/f1 /var/spool/uucppublic/f2 amy -dC D.herae73655 777 1gh`
where:
 - a. S denotes that the **uucp** command is sending the file.
 - b. The full path name of the source file is /home/amy/f1.
 - c. The full path name of the destination is /var/spool/uucppublic/f2, where /var/spool/uucppublic is the name of the BNU public spooling directory on the remote computer and f2 is the new name of the file.
2. The /var/spool/uucp/hera/C.zeusN3130 send command file, produced by the **uuto** command, is as follows:

```
S /home/amy/out ~/receive/msg/zeus amy -dcn D.0 777 msg
```

The S denotes that the /home/amy/out source file was sent to the receive/msg subdirectory in the public spooling directory on system zeus by user amy.

Note: The **uuto** command creates the **receive/msg** directory if it does not already exist.

The **uuto** command used the default flags **-d** (create directories), **-c** (transfer directly, no spooling directory or data file), and **-n** (notify recipient). The **D.0** notation is a placeholder, 777 is the permissions code, and **msg** is the recipient.

Receive Command File

The format of a receive command file is somewhat different from that of a send command file. When files required to run a specified command on a remote system are not present on that system, the **uux** command creates a receive command file.

For example, the following command:

```
uux - "diff /home/amy/out hera!/home/amy/out2 > ~/DF"
```

produces the /var/spool/uucp/zeus/C.heraR1e94 receive command file.

Note: The command in this example invokes the **uux** command to run a **diff** command on the local system, comparing file /home/amy/out with file /home/amy/out2, which is stored on the remote system hera. The output of the comparison is placed in the DF file in the public directory on the local system.

The actual receive command file looks like this:

```
R /home/amy/out2 D.hera1e954fd amy - dummy 0666 amy
```

The R denotes a receive file. The **uucico** daemon, called by the **uux** command, gets the `/home/amy/out2` file from system hera and places it in a data file called `D.hera1e954fd` for the transfer. Once the files are transferred, the **uuxqt** daemon executes the command on the specified system.

User amy issued the **uux** command with the - (minus sign) flag, which makes the standard input to the **uux** command the standard input to the actual command string. No data file was created in the local spooling directory, so the BNU program uses **dummy** as a placeholder. The permissions code is 666 (the BNU program prefixes the three-digit octal code with a 0), and user amy is to be notified when the command has finished executing.

Files

| Item | Description |
|---|---|
| <code>/etc/uucp/Permissions</code> | Describes access permissions for remote systems. |
| <code>/etc/uucp/Systems</code> | Describes accessible remote systems. |
| <code>/etc/uucp/Sysfiles</code> file | Specifies possible alternative files for <code>/etc/uucp/Systems</code> . |
| <code>/var/spool/uucp/SystemName/D.*</code> | Contains data to be transferred. |
| <code>/var/spool/uucp/SystemName</code> directory | Contains BNU command, data, and execute files. |
| <code>/var/spool/uucppublic/*</code> directory | Contains transferred files. |

[BNU File and Directory Structure](#)

compver File

Purpose

Describes the format of a compatible versions file.

Description

The **compver** file is an ASCII file used to specify previous versions of the associated package which are upward compatible. It is created by a package developer.

Each line of the file specifies a previous version of the associated package with which the current version is backward compatible.

Since some packages may require installation of a specific version of another software package, compatibility information is extremely crucial. Consider, for example, a package called "A" which requires version "1.0" of application "B" as a prerequisite for installation. If the customer installing "A" has a newer version of "B" (1.3), the **compver** file for "B" must indicate that "1.3" is compatible with version "1.0" in order for the customer to install package "A."

The comparison of the version string disregards white space and tabs. It is performed on a word-by-word basis. Thus **Version 1.3** and **Version 1.3** would be considered the same.

Examples

An example of a **compver** file is shown below.

Version 1.3
Version 1.0

Related reference:

"depend File" on page 72

config File

Purpose

Contains audit system configuration information.

Description

The **/etc/security/audit/config** file is an ASCII stanza file that contains audit system configuration information. This file contains five stanzas: **start**, **bin**, **stream**, **classes**, and **users**.

start Stanza

The **start** stanza contains the attributes used by the **audit start** command to initialize the audit system. The format follows:

```
start:  
  fullpath = off | on  
  binmode = off | on | panic  
  streammode = off | on
```

The attributes are defined as follows:

| Attribute | Definition |
|-------------------|---|
| binmode | Controls whether bin collection, as defined in the bin stanza, is used. off Bin collection is not used. This is the default value. on Bin collection is used. This value starts the auditbin daemon. panic Bin collection is used. This value starts the auditbin daemon. If an audit record cannot be written to a bin, the kernel shuts down the operating system. This mode should be specified for conditions during which the system must be working properly. |
| fullpath | Captures the full path name of a file for the FILE_Open, FILE_Read, and FILE_Write auditing events. off Full path name is not recorded. This is the default value. on Full path name is recorded. |
| streammode | Controls whether stream data collection, as defined in the file specified in the stream stanza (normally the /etc/security/audit/streamcmds file), is configured at the start up of the audit system. off Stream data collection is not enabled. This is the default value. on Stream data collection is enabled. |

Note: If neither collection mode is defined or if both modes are in the **off** state, only subsystem configuration is done.

bin Stanza

The **bin** stanza contains the attributes used by the **auditbin** daemon to set up bin mode auditing. The format follows:

```
bin:  
  trail = PathName  
  bin1 = PathName  
  bin2 = PathName  
  binsize = DecimalString  
  cmds = PathName
```

```

bytethreshold = DecimalString
eventthreshold = DecimalString
freespace = DecimalString
backuppath = DirectoryPath
backupsize = DecimalString
virtual_log = PathName
bincompact = off | on

```

Bin mode parameters are defined as follows:

| Parameter | Definition |
|-----------------------|---|
| <i>trail</i> | Specifies the path name of the audit trail file. When this is defined, the auditbin daemon can substitute the path name of the audit trail file for the \$trail string in the backend commands that it calls. |
| <i>bin1</i> | Specifies the path name that the auditbin daemon uses for its primary bin file. If the \$bin string is the parameter value, the auditbin daemon substitutes the name of the current bin file. |
| <i>bin2</i> | Specifies the path name that the auditbin daemon uses for its secondary bin file. If the \$bin string is the parameter value, the auditbin daemon substitutes the name of the current bin file. |
| <i>bincompact</i> | Specifies if compact audit log mode should be enabled for the bin mode auditing. The two possible values are on and off. The default value is off. |
| <i>binsize</i> | Specifies a decimal integer string that defines the threshold size (in bytes) of each audit bin. If the <i>binsize</i> parameter is set to 0, no bin switching will occur, and all bin collection will go to <i>bin1</i> . |
| <i>cmds</i> | Specifies the path name of the file that contains the audit backend commands called by the auditbin daemon. The file contains command lines, each composed of one or more backend commands with input and output that can be piped together or redirected. See the description of the <i>/etc/security/audit/bincmds</i> file for more information. |
| <i>bytethreshold</i> | Specifies the decimal integer string that defines the approximate number of bytes written to an audit bin before a synchronous update is performed. If the bytethreshold is set to 0, this function is disabled. Both bytethreshold and eventthreshold can be used simultaneously. |
| <i>eventthreshold</i> | Specifies a decimal integer string that defines the maximum number of events written to an audit bin before a synchronous update is performed. If the eventthreshold is set to 0, this function is disabled. Both eventthreshold and bytethreshold can be used simultaneously. |
| <i>freespace</i> | Specifies a decimal integer string that defines the recommended number of 512-byte free blocks in the file system where the audit trail file is located. If the free space of file system is below this value, audit generates a warning message through the syslog subsystem every time that the audit bin is switched. The default value is 65536 blocks (64 megabytes). The maximum possible value is 4194303 (about 2GB of free disk space). If this value is set to 0, no warning message is generated. If the valid backuppath is mentioned and free space of file system is below this value, auditcat will take the backup of the trail file in this path every time auditbin invokes the auditcat . |
| <i>backuppath</i> | Specifies the absolute path name of the directory, where the backup of the trail file is need to be copied, when it reaches to backupsize. See the description of the auditcat command for more information. |
| <i>backupsize</i> | Specifies a decimal integer string that defines the recommended number of 512-byte blocks in the trail file. If the trail file size is equal to or greater than this value, backup of the trail is taken. The default value is empty (backup is disable). The maximum possible value is 4194303 (about 2GB of free disk space). If this value is set to <=0 or any invalid value this parameter will be ignored. See the description of the auditcat command for more information. |
| <i>virtual_log</i> | Specifies the path name for a <i>virtual_log</i> device. The virtual log facility can be used by the auditbin daemon to write audit records into an attached VIOS system. To enable the <i>virtual_log</i> device on a client LPAR, first configure the corresponding vlog device on attached VIOS system, and then specify a newly created device on a client (for example, <i>/dev/vlog0</i> device can be specified). |

stream Stanza

The **stream** stanza contains the attributes that the **audit start** command uses to set up initial stream mode auditing. The format follows:

```
cmds = PathName
```

The *PathName* parameter identifies the file that contains the stream commands that are executed at the initialization of the audit system. These commands can use shell piping and redirection, but no substitution of path names is performed on **\$trail** or **\$bin** strings.

classes Stanza

The **classes** stanza defines audit classes (sets of audit events) to the system.

Each audit class name must be less than 16 characters and be unique on the system. Each class definition must be contained in a single line, with a new line acting as a delimiter between classes. The system supports up to 32 audit classes, with ALL as the last class. The audit events in the class must be defined in the **/etc/security/audit/events** file.

```
classes:  
    auditclass = auditevent, ...auditevent
```

users Stanza

The **users** stanza defines audit classes (sets of events) for each user. The classes are defined to the operating system kernel.

The format is as follows:

```
users:  
    UserName = auditclass, ... auditclass
```

Each **UserName** attribute must be the login name of a system user or the string **default**, and each **auditclass** parameter should be defined in the **classes** stanza.

To establish the audit activities for a user, use the **chuser** command with the **auditclasses** attribute.

role Stanza

The role stanza defines audit classes (sets of events) for each role. The classes are defined for the operating system kernel.

The format of the role stanza is as follows:

```
role:  
    RoleName = auditclass, ... auditclass
```

Each **RoleName** attribute must be the name of a system role or the string **default**, and each **auditclass** parameter must be defined in the **classes** stanza.

To establish the audit activities for a role, use the **chrole** command with the **auditclasses** attribute.

WPARS Stanza

The **WPARS** stanza defines audit classes (sets of events) for each workload partition (WPAR). The classes are defined to the operating system kernel.

The **WPARS** stanza has the following format:

```
WPARS:  
    wpar_name = auditclass, ... auditclass
```

Each **wpar_name** must be the WPAR name of a system. You must define each **auditclass** parameter in the **classes** stanza.

Security

Access Control: This file should grant read (r) access to the root user and members of the audit group and write (w) access only to the root user.

| Event | Information |
|---------------|-------------|
| AUD_CONFIG_WR | file name |

Examples

1. To define audit classes, add a line to the **classes** stanza of the **/etc/security/audit/config** file for each set of events that you want to assign to a class:

```
classes:
  general = USER_SU,PASSWORD_Change,FILE_Unlink,
             FILE_Link,FILE_Remove
  system = USER_Change,GROUP_Change,USER_Create,
            GROUP_Create
  init = USER_Login, USER_Logout
```

These specific audit events and audit classes are described in "Setting Up Auditing" in *Operating system and device management*.

2. To establish the audit activities for each user, use the **chuser** command with the **auditclasses** attribute for each user for whom you want to define audit classes (sets of audit events):

```
chuser "auditclasses=general,init,system" dave
chuser "auditclasses=general,init" mary
```

These **chuser** commands create the following lines in the **users** stanza of the **/etc/security/audit/config** file:

```
users:
  dave=general,init,system
  mary=general,init
```

This configuration includes dave, the administrator of the system, and mary, an employee who updates information.

3. To enable the auditing system, turn on bin data collection, and turn off initial stream data collection, add the following to the **start** stanza of the **/etc/security/audit/config** file:

```
start:
  binmode = on
  streammode = off
```

4. To enable the **auditbin** daemon to set up bin collection, add attributes to the **bin** stanza of the **/etc/security/audit/config** file:

```
bin:
  trail = /audit/trail
  bin1 = /audit/bin1
  bin2 = /audit/bin2
  binsize = 25000
  cmd = /etc/security/audit/bincmds
```

The attribute values in the preceding stanza enable the audit system to collect bin files of data and store the records in a long-term audit trail.

5. To enable the **auditbin** daemon to set up stream collection, add lines to the **start** and **stream** stanzas of the **/etc/security/audit/config** file:

```
start:
  streammode = on
stream:
  cmd = /etc/security/audit/streamcmds
```

6. To enable the wpar1 WPAR to audit the general, tcpip, and lvm classes, add the following lines to the **WPARS** stanza of the **/etc/security/audit/config** file:

```
WPARS:
  wpar1 = general,tcpip,lvm
```

7. To enable the virtual logs in the **auditbin** daemon for capturing audit records in a centralized place, such as a Virtual I/O Server (VIOS) system, add the following attribute to the **bin** stanza of the **/etc/security/audit/config** file:

```
bin:  
virtual_log = /dev/vlog0
```

Note: The `/dev/vlog0` device path is an example. The real device name might be different on each client logical partition (LPAR), based on how the virtual logs are configured from an attached VIOS system.

Files

| Item | Description |
|---|--|
| <code>/etc/security/audit/config</code> | Specifies the path to the file. |
| <code>/etc/security/audit/objects</code> | Contains audit events for audited objects. |
| <code>/etc/security/audit/events</code> | Contains the audit events of the system. |
| <code>/etc/security/audit/bincmds</code> | Contains auditbin backend commands. |
| <code>/etc/security/audit/streamcmds</code> | Contains auditstream commands. |

consdef File

Purpose

Enables asynchronous tty devices to be console candidates at system boot when no console device is defined or available.

Description

The `/etc/consdef` file enables tty devices such as terminals and modems to be chosen as the console device. When the console device is undefined, the system displays a message on all natively attached graphics displays and the tty on native serial port S1. The console device is undefined when:

- The system is first installed and started.
- The console definition has been deleted from the ODM database.
- The console device has been physically removed from the system.

If any of these conditions occur, the system displays the following message:

```
***** Please define the System Console. *****  
Type a Number and press <Enter> to use this terminal as the system console.
```

For high function terminals (HFTs)graphics displays, the *Number* variable refers to a function key. For asynchronous ttys, this variable is a number.

The selected item becomes the system console. To choose a non-default tty device as the system console, you must first configure the `/etc/consdef` file. This file contains stanzas that define various console attributes. Each line, or entry, in a stanza must take the form of *Attribute=Value*, and the line must not exceed 80 characters. The following attributes must be defined for each terminal device:

| Attribute | Definition |
|-------------------|--|
| connection | Identifies the type of tty interface. Valid values are rs232 and rs422. |
| location | Specifies the location code of the terminal. Location codes of 00-00-S1-00 or 00-00-S2-00 indicate that the tty device is attached to the S1 or S2 serial port, respectively. Any other location code indicates the tty device is attached to an adapter card other than the standard I/O planar. You can display valid location values with the lsdev -C grep tty command. |

You can also specify other terminal attributes such as **speed**, **bpc**, **stops**, **parity**, and **term**. If you do not define these attributes, the system uses the default values stored in the ODM database. The **consdef** file contains a sample stanza for the S1 port. To enable this stanza, or parts of it, remove the comment delimiters (#) from each applicable line.

Examples

To display the console selection message on the ttys attached to the S1 and S2 ports:

```
ALTTTY:
connection=rs232
location=00-00-S1-00
speed=9600
bpc=8
stops=1
parity=none
term=ibm3163

ALTTTY:
connection=rs232
location=00-00-S2-00
speed=9600
bpc=8
stops=1
parity=none
term=ibm3163
```

Note: For compatibility with earlier versions, the ALTTTY: keyword is not required for the first entry.

Files

copyright File

Purpose

Describes the format of a copyright information file.

Description

The **copyright** file is an ASCII file used to provide a copyright notice for a package. The text may be in any format. The full file contents (including comment lines) is displayed on the terminal at the time of package installation.

ct_class_ids File

Purpose

Contains the mapping of resource class names to resource class IDs for the RMC subsystem.

Description

The **ct_class_ids** file contains the mapping of resource class names to resource class IDs for the RMC subsystem. This file is a read-only file; the contents cannot be modified.

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Location

/opt/rsct/cfg/ct_class_ids

Related information:

mkcimreg Command

ct_cssk.kf File

Purpose

Contains the cluster shared secret key.

Description

In a peer domain with the cluster shared secret key (CSSK) function enabled, the configuration resource manager creates a file called **ct_cssk.kf** in the **/var/ctl/domain_name/cfg** directory and stores the initial CSSK in it. A **ct_cssk.kf** file is then created on each node that is online in the peer domain.

The topology services subsystem uses the CSSK to provide message authentication, which ensures the integrity of messages that are sent between nodes within the peer domain. Once the CSSK function is enabled for a peer domain, all RMC, topology services, and group services message traffic is signed for authentication using the CSSK.

Any changes to the CSSK are coordinated across all nodes that are online in the peer domain and any offline nodes when they join the peer domain. The new key is distributed to all online nodes in the peer domain using the current CSSK. On each online node, the configuration resource manager replaces the key value in **/var/ctl/domain_name/cfg/ct_cssk.kf** with the new value, and then refreshes the topology services subsystem to pick up the new key. Once refreshed, the new key is in effect for message authentication.

Security

The permissions of this file are **000**. Effectively, only **root** has read and write access to this file.

Restrictions

The configuration resource manager manages this file automatically. It must not be modified by any other user or program.

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

rmrpdomain Command

startrpdomain Command

ct_has.pkf File

Purpose

Default location for the local node's cluster security services public key file.

Description

The `/var/ct/cfg/ct_has.pkf` file is the default location where the `ctcasd` daemon will expect to find the local node's public key file. The public key is stored in a proprietary binary format.

The `ctcasd.cfg` file permits the system administrator to specify an alternate location for this file. The `ctskeygen -p` command permits the administrator to create this file in an alternate location. If an alternate location is used, the file must meet all the criteria listed in the **Security** section of this man page. The file must not be recorded to a read-only file system, because this will prohibit the system administrator from modifying the contents of this file in the future.

If the `ctcasd` daemon cannot locate this file during its startup, it will check for the presence of the `ct_has.qkf` file. If both files are missing, the daemon assumes that it is being started for the first time after installation, and create an initial private and public key file for the node. The daemon also creates the initial trusted host list file for this node. This file contains an entry for `localhost` and the host names (or IP addresses) associated with all AF_INET-configured adapters that the daemon can detect. This may cause inadvertent authentication failures if the public and private key files were accidentally or intentionally removed from the local system before the daemon was restarted. `ctcasd` will create new keys for the node, which will not match the keys stored on the other cluster nodes. If UNIX-identity-based authentication suddenly fails after a system restart, this is a possible source of the failure.

If the public key file is missing but the private key file is detected, the daemon concludes that the local node is misconfigured and terminates. A record is made to persistent storage to indicate the source of the failure.

Security

This file is readable to all users on the local system. Write permission is not granted to any system user.

By default, this file is stored in a locally-mounted file system. The `ctcasd.cfg` file permits system administrators to change the location of the file. Should system administrators use a different location, it is the administrator's responsibility to assure that the file is always accessible to the local node, and that

all users from this local node can read the file. If the storage location does not meet these criteria, users and applications will be unable to authenticate to trusted services using UNIX-identity-based authentication.

If the system administrator chooses to place this file in a networked file system, the administrator must assure that no two nodes are attempting to use the same physical file as their own public key file. Because public keys differ between nodes, if two nodes attempt to use the same public key file, at least one of them will always obtain the incorrect value for its public key. This will cause applications and users from that node to fail authentication to trusted services within the cluster.

Restrictions

Cluster security services supports only its own private and public key formats and file formats. Secured Remote Shell formats are currently unsupported. Settings for the HBA_USING_SSH_KEYS attribute are ignored.

Examples

This example shows the default contents of the configuration file:

```
TRACE= ON

```

Location

/var/ct/cfg/ct_has.pkf
Contains the **ct_has.pkf** file

Files

/opt/rsct/cfg/ctcasd.cfg
Default location of the **ctcasd.cfg** file

ct_has.qkf File

Purpose

Default location for the cluster security services private key file for the local node.

Description

The **/var/ct/cfg/ct_has.qkf** file is the default location where the **ctcasd** demon expects to find the local node's private key file. The private key is stored in a proprietary binary format.

The **ctcasd.cfg** file permits the system administrator to specify an alternate location for this file. The **ctskeygen -q** command permits the administrator to create this file in an alternate location. If an alternate location is used, the file must meet all the criteria listed in the **Security** section of this man page. The file must not be recorded to a read-only file system, because this will prohibit the system administrator for modifying the contents of this file in the future

If the **ctcasd** demon cannot locate this file during its startup, it will check for the presence of the **ct_has.pkf** file. If both files are missing, the demon will assume that it is being started for the first time after installation, and create an initial private and public key file for the node. The demon also creates the initial trusted host list file for this node. This file contains an entry for **localhost** and the host names (or IP addresses) associated with all AF_INET-configured adapters that the demon can detect. This may cause inadvertent authentication failures if the public and private key files were accidentally or intentionally removed from the local system before the demon was restarted. **ctcasd** will create new keys for the node, which will not match the keys stored on the other cluster nodes. If UNIX-identity-based authentication suddenly fails after a system restart, this is a possible source of the failure.

If the private key file is missing but the public key file is detected, the demon concludes that the local node is not configured accurately and terminates. A record is made to persistent storage to indicate the source of the failure.

Security

This file is readable and accessible only to the root user. Access to all other users is not provided.

By default, this file is stored in a locally mounted file system. The **ctcasd.cfg** file permits system administrators to change the location of the file. Should system administrators use a different location, it is the administrator's responsibility to assure that the file is always accessible to the local node, and that only the root user from this local node can access the file. If the storage location does not meet these criteria, the security of the node and the cluster should be considered compromised.

Restrictions

Cluster security services supports only its own private and public key formats and file formats. Secured Remote Shell formats are currently unsupported. Settings for the HBA_USING_SSH_KEYS attribute are ignored.

Examples

This example shows the default contents of the configuration file:

```

```

Location

/opt/rsct/bin/ct_has.qkf

Location of the **ct_has.qkf** file.

Files

/opt/rsct/cfg/ctcasd.cfg

Default location of the **ctcasd.cfg** file

ct_has.thl File

Purpose

Default location for the local node's cluster security services trusted host list file.

Description

The **/var/ct/cfg/ct_has.thl** file is the default location where the **ctcasd** daemon expects to find the local node's trusted host list file. The contents of this file are stored in a proprietary binary format.

The trusted host list maps each host identity within the peer domain or management domain to the host's cluster security services public key. The **ctcasd** daemon uses this list to determine which nodes on the network are trusted, and to locate the public keys for these nodes in order to decrypt UNIX-identity-based credentials transmitted from another host within the cluster. If a host is not listed in a node's trusted host list, or if the public key recorded for that host is incorrect, the host will not be able to authenticate to that node using UNIX-identity-based authentication.

The **ctcasd.cfg** file permits the system administrator to specify an alternate location for this file. If an alternate location is used, the file must meet all the criteria listed in the **Security** section of this man page. The file must not be recorded to a read-only file system, because this will prohibit the system administrator for modifying the contents of this file in the future.

If the **ctcasd** daemon cannot locate this file during its startup, it will check for the presence of the **ct_has.pkf** file. If both files are missing, the daemon will assume that it is being started for the first time after installation, and create an initial private and public key file for the node. The daemon also creates the initial trusted host list file for this node. This file contains an entry for **localhost**, along with the IP

addresses and the host names associated with all AF_INET-configured adapters that the daemon can detect. This may cause inadvertent authentication failures if the public and private key files were accidentally or intentionally removed from the local system before the daemon was restarted. The **ctcasd** daemon creates new keys for the node, which will not match the keys stored on the other cluster nodes. If UNIX-identity-based authentication suddenly fails after a system restart, this is a possible source of the failure.

Security

This file is readable by all users on the local system. Write access is not provided to any system user.

By default, this file is stored in a locally-mounted file system. The **ctcasd.cfg** file permits system administrators to change the location of the file. If the system administrator uses a different location, it is the administrator's responsibility to make sure the file is always accessible to the local node, and that all users from this local node can access the file. If the storage location does not meet these criteria, users and applications will be unable to authenticate to trusted services using UNIX-identity-based authentication.

If the system administrator chooses to place this file in a networked file system, the administrator must assure that no two nodes are attempting to use the same physical file as their own trusted host list file, or that the file does not contain an entry for localhost. By default, the trusted host list contains an entry for **localhost**, which maps the local system's public key to this value. If multiple hosts share the same trusted host list file, attempts by users or applications to contact localhost for trusted services may fail because the entry maps to an incorrect public key value.

Restrictions

- Cluster security services supports only its own private and public key formats and file formats.
- Cluster security services does not provide an automated utility for creating, managing, and maintaining trusted host lists throughout the cluster. This is a procedure left to either the system administrator or the cluster management software.

Examples

This example shows the default contents of the configuration file:

```
TRACE= ON
TRACEFILE= /var/ct/IW/log/ctsec/ctcasd/trace

Location of the **ct_has.thl** file.

Files

/opt/rsct/cfg/ctcasd.cfg

Default location of the **ctcasd.cfg** file

ctfile.cfg File

Purpose

Controls tracing and logging for various RSCT components.

Description

To initiate tracing and logging control, system administrators can create the RSCT file configuration (RFC) file, **/etc/ctfile.cfg**. A system administrator can copy a sample configuration file, **/opt/rsct/cfg/ctfile.cfg**, to the **/etc** directory, and then modify it. The control information in the configuration file takes effect the next time a specified component, a daemon, for example, is started.

RSCT components that support tracing and logging control, which are listed in the sample configuration file, obtain the following information from **/etc/ctfile.cfg**:

- An absolute path to a directory tree under which the component trace files and log files are to be written. This path can refer to a remote file system.
- A flag that indicates whether tracing is to be disabled for each component.
- A flag that indicates whether tracing is to be disabled for all RSCT components.
- When tracing is enabled, the size of a trace file for each component and each trace file. Some components write to several trace files.
- The amount of information to be traced.
- A flag that indicates whether logging is to be disabled for each component.
- A flag that indicates whether logging is to be disabled for all RSCT components.

Lines that consist of only the characters NL or white space are ignored. If the first non-white-space character of a line is the number sign character (#), the line is a comment, so it is ignored. All other lines must contain one or more tokens. If there is more than one token on a line, the tokens must be separated by white space. A token line can contain leading or trailing white space. White space is any mix of the blank and tab characters.

The trace and log root directory token

The trace and log root directory token is a name/value pair. The format is:

CT_TRACE_LOG_ROOT_DIR=path_name

The path name must be absolute. If this token is not specified, the trace and log root directory is assumed to be **/var/ct**. In either case, all trace and log file path names are constructed with the trace and log root directory as the path name prefix.

The trace disable token

The trace disable token is a name/value pair followed by an optional component name. The format is:

```
CT_TRACE_DISABLE={true|false} [component_name]
```

This token can be specified more than once, each on a separate line. If this token is not specified then tracing is enabled for all components that reference this file and are not otherwise specified in another trace disable token line. If this token is specified with a value of true, and no component name is specified, tracing is disabled for all components that reference this file and are not otherwise specified in another trace disable token line. If this token is specified with a value of false, and no component name is specified, then tracing is enabled for all components that reference this file and are not otherwise specified in another trace disable token line. If a component name is specified then tracing for that component is enabled or disabled to match the value false or true, respectively. For a component, the token line that specifies that component has precedence over any token line that does not specify a component. If more than one token line specifies the same component, the last such token line has precedence. Component names are the resource manager names in the case of resource managers (as derived from the resource manager .mdef file), mc in the case of the RMC daemon and ctcasd in the case of the cluster authentication services daemon. Specifically, the component name must be the name used in constructing the full path name of a trace file. Here is an example:

```
CT_TRACE_DISABLE=true  
CT_TRACE_DISABLE=false mc  
CT_TRACE_DISABLE=false IBM.MgmtDomainRM
```

Tracing is enabled for the management domain resource manager and the RMC daemon. For all other components trace is disabled.

The trace file size token

The trace file size token is a name/value pair followed by a component name and trace file name. It has the following form:

```
CT_TRACE_FILE_SIZE=nnn[K] component_name file_name
```

where *nnn* is the size of the specified trace file in bytes. If the optional K suffix is specified, the size is specified in units of 1024 bytes. The RSCT trace facility rounds up file sizes to a page boundary. If a trace file size token is not specified, components use the file sizes that are programmed into the component.

The trace level token

The trace level token is a name/value pair followed by a component name. The format is:

```
CT_TRACE_LEVELS=string component_name
```

The level string is in standard trace facility format, for example, Comp_ID:category=level. If a trace level token is not specified, components use the trace levels programmed into the component. Trace levels determine the amount of information recorded in a trace file.

The logging disable token

The logging disable token is a name/value pair followed by an optional component name. The format is:

```
CT_LOGGING_DISABLE={true|false} [component_name]
```

This token can be specified more than once, each on a separate line. If this token is not specified, logging is enabled for all components that refer to this file and are not otherwise specified in another logging disable token line. If this token is specified with a value of true and no component name is specified, logging is disabled for all components that refer to this file and are not otherwise specified in another logging disable token line. If this token is specified with a value of false and no component name is

specified, logging is enabled for all components that refer to this file and are not otherwise specified in another logging disable token line. If a component name is specified, logging for that component is enabled or disabled to match the value **false** or **true**, respectively. For a component, the token line that specifies that component has precedence over any token line that does not specify a component. If more than one token line specifies the same component, the last such token line has precedence. Component names are the resource manager names in the case of resource managers (as derived from the resource manager's **.mdef** file), **mc** in the case of the RMC daemon and **ctcasd** in the case of the cluster authentication services daemon. Specifically, the component name must be the name that is used in constructing the full path name of a logging file.

Files

/etc/ctfile.cfg

Location of the RSCT file configuration (RFC) file that is created by the system administrator

/opt/rsct/cfg/ctfile.cfg

Location of the sample **ctfile.cfg** file

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) filesset for AIX.

Location

/etc/ctfile.cfg

Related information:

ctsnap Command

ctgroups File

Purpose

Contains the group name of the cluster administration group.

Description

The **ctgroups** file stores the group name of the cluster administration group. In addition, **ctgroups** caches the corresponding group ID.

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) cluster security services. It is shipped as part of the **rsct.core.sec** filesset for AIX.

Location

/var/ct/cfg/ctgroups

Contains the **ctgroups** file

Related information:

ctadmingroup Command

ctcas_hba2.map File

Purpose

Defines the operating system identity that the RSCT enhanced host-based authentication (HBA2) security mechanism uses for service provider applications on a node.

Description

Applications that use the cluster security services library must obtain an identity from the security mechanisms supported by the library. These identities are specific to the individual security mechanisms supported by cluster security services. Because cluster security services support multiple security mechanisms and multiple applications, the cluster security services library must be informed of which identity to use for an application when interacting with a specific security mechanism on its behalf.

The **ctcas_hba2.map** file defines the identities that the core cluster applications use when they interact with RSCT HBA2. The cluster security services library expects to find this file in **/var/ct/cfg/ctcas_hba2.map** (preferred) or **/opt/rsct/cfg/ctcas_hba2.map** (default).

This file is ASCII-text formatted, and can be modified with a standard text editor. However, this file must not be modified unless the administrator is instructed to do so by the cluster software service provider. If this configuration file is to be modified, the default **/opt/rsct/cfg/ctcas_hba2.map** file must not be modified directly. Instead, the file must be copied to **/var/ct/cfg/ctcas_hba2.map**, and modifications must be made to this copy. The default configuration file must never be modified.

All entries within this file use the following format:

SERVICE:service_name:user_name_running_the_service

| Attribute | Definition |
|--------------------------------------|--|
| SERVICE | Required keyword |
| <i>service_name</i> | Specifies the name commonly used to refer to the application. For example, it can be the name used by the system resource controller to refer to this application. |
| <i>user_name_running_the_service</i> | Specifies the operating system user identity used to run the application process. It is the owner identity that would be seen for the application process in the ps command output. |

Files

/var/ct/cfg/ctcas_hba2.map

Restrictions

This file must not be modified unless the administrator is instructed to do so by the cluster software service provider. Incorrect modification of this file results in authentication failures for the applications listed in this file and possibly their client applications. If this configuration file is to be modified, the default **/opt/rsct/cfg/ctcas_hba2.map** file must not be modified directly. Instead, the file must be copied to **/var/ct/cfg/ctcas_hba2.map**, and modifications must be made to this copy. The default configuration file must never be modified.

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) cluster security services. It is shipped as part of the **rsct.core.sec** fileset for AIX.

Location

/opt/rsct/cfg/ctcas_hba2.map

Examples

This example shows the default contents of the configuration file:

```
SERVICE:ctrmc:root  
SERVICE:rmc:root  
SERVICE:ctloadl:loadl  
SERVICE:ctdpcl:root  
SERVICE:ctpmd:root
```

Related information:

ps Command
ctcasd Command

ctcasd.cfg File

Purpose

Provides operational parameters to the cluster security services daemon **ctcasd**.

Description

The **ctcasd.cfg** configuration file defines the operational parameters to the cluster security services daemon **ctcasd**. The **ctcasd** daemon reads this file when it (the daemon) initializes. The **ctcasd** daemon expects to find this configuration file in either the **/var/ct/cfg** directory (preferred) or in the **/opt/rsct/cfg** directory (default). System administrators can modify the contents of the file stored in the **/var/ct/cfg** directory, but should not modify the default version of the file in **/opt/rsct/cfg** unless instructed to do so by the cluster software service provider.

This file is ASCII-formatted, and can be modified using any available text editor. One attribute can be defined per line within this file. Attributes are specified as follows:

attribute=value

The following attributes are defined:

| Attribute | Definition |
|-----------|------------|
|-----------|------------|

TRACE

Indicates whether daemon tracing is activated. Acceptable values are **ON** and **OFF**. If the **TRACE** attribute is not listed in the **ctcasd.cfg** file, tracing is not activated. For coexistence with earlier versions of RSCT, **TRACE=false** is interpreted as **TRACE=OFF**.

TRACEFILE

Specifies the fully-qualified path name where daemon tracing information is to be recorded.

TRACELEVELS

Indicates the tracing granularity employed by the daemon when tracing is activated. The possible trace categories are:

_SEC:Errors

Captures error information in the trace log. Possible values are: **1**, **2**, **4**, and **8**.

_SEC:API

Tracks the entry and exit of subroutines within the daemon. Possible values are: **1** and **8**.

_SEC:Perf

Captures performance-related information. Possible values are: **1**, **4**, and **8**.

_SEC:Info

Traces the general execution progress of the daemon. Possible values are: **1**, **2**, **3**, **4**, and **7**.

When setting the values of these trace categories, keep in mind that the lower the number is, the less intrusive (and less detailed) the trace will be. Multiple traces can be enabled at once. For

example, if an administrator wants to enable a trace that captures basic performance data and highly-detailed error data, the specification for TRACELEVELS would be:

```
TRACELEVELS=_SEC:Perf=1,_SEC:Errors=8
```

TRACESIZE

Specifies the size of the trace file in bytes. The default value is 1 megabyte.

RQUEUESIZE

Indicates the maximum length permitted for the daemon's internal run queue. If this value is not set, a default value of 64 is used.

MAXTHREADS

The limit to the number of working threads that the daemon may create and use at any given time (the "high water mark"). If this value is not set, a default value of 10 is used.

MINTHREADS

The number of idle threads that the daemon will retain if the daemon is awaiting further work (the "low water mark"). If this value is not set, a default value of 4 is used.

THREADSTACK

Sets the internal memory used by the daemon for thread stack space. The value is expressed in bytes. If no value is specified, the default system thread stack size is used. This value should not be modified by the administrator unless instructed to do so by IBM® Service.

HBA_USING_SSH_KEYS

Indicates whether the daemon is making use of Secured Remote Shell keys. Acceptable values are **true** and **false**. If this value is not defined, a default value of **false** is used. See **Restrictions**.

HBA_PRVKEYFILE

Provides the full path name of the file that contains the local node's private key. If this value is not set, the default location of **/var/ct/cfg/ct_has.qkf** is used.

HBA_PUBKEYFILE

Provides the full path name of the file that contains the local node's public key. If this value is not set, the default location of **/var/ct/cfg/ct_has.pkf** is used.

HBA_THLFILE

Provides the full path name of the file that contains the local node's trusted host list. If this value is not set, the default location of **/var/ct/cfg/ct_has.thl** is used.

HBA_KEYGEN_METHOD

Indicates the method to be used by **ctcasd** to generate the private and public keys of the local node if the files containing these keys do not exist. Acceptable values are those that can be provided as arguments to the **ctskeygen -m** command. If no value is provided for this attribute, the default value of **rsa1024** is used.

SERVICES

Lists the internal cluster security services library services that the daemon supports. This entry should not be modified by system administrators unless they are explicitly instructed to do so by the cluster security software service provider.

Restrictions

Cluster security services supports only its own private and public key formats and file formats. Secured Remote Shell formats are currently unsupported. Settings for the HBA_USING_SSH_KEYS attribute are ignored.

Examples

This example shows the default contents of the configuration file:

```
TRACE= ON
TRACEFILE= /var/ct/IW/log/ctsec/ctcasd/trace
TRACELEVELS= _SEC:Info=1,_SEC:Errors=1
TRACESIZE= 1003520
RQUEUESIZE=
MAXTHREADS=
MINTHREADS=
THREADSTACK= 131072
HBA_USING_SSH_KEYS= false
HBA_PVKFILE=
HBA_PUBKEYFILE=
HBA_THLFILE=
HBA_KEYGEN_METHOD= rsa512
SERVICES=hba CAS
```

After modification, the contents of the configuration file might look like this:

```
TRACE= ON
TRACEFILE= /var/ct/IW/log/ctsec/ctcasd/trace
TRACELEVELS= _SEC:Perf=1,_SEC:Errors=8
TRACESIZE= 1003520
RQUEUESIZE= 64
MAXTHREADS= 10
MINTHREADS= 4
THREADSTACK= 131072
HBA_USING_SSH_KEYS= false
HBA_PVKFILE= /var/ct/cfg/qkey
HBA_PUBKEYFILE= /var/ct/cfg/pkey
HBA_THLFILE= /var/ct/cfg/thl
HBA_KEYGEN_METHOD= rsa512
SERVICES= hba CAS
```

Location

/var/ct/cfg/ctcasd.cfg
Contains the **ctcasd.cfg** file

Files

/opt/rsct/cfg/ctcasd.cfg
Default location of the **ctcasd.cfg** file

ctrmc.acls File

Purpose

Contains a node's resource monitoring and control (RMC) access control list (ACL).

Description

RMC implements authorization using an access control list (ACL) file. Specifically, RMC uses the ACL file on a particular node to determine the permissions that a user must have in order to access resource classes and their resource instances. A node's RMC ACL file is named **ctrmc.acls** and is installed in the directory **/opt/rsct/cfg**. You can allow RMC to use the default permissions set in this file, or you can modify the file after copying it to the directory **/var/ct/cfg/**. For more information, see the *RSCT: Administration Guide*.

For information about how access controls are implemented for the **IBM.LPCommands** resource class and its resources, see the **Ipacl** information file.

Implementation Specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Location

/var/ct/cfg/ctrmc.acls

Contains the **ctrmc.acls** file

Files

/opt/rsct/cfg/ctrmc.acls

Default location of the **ctrmc.acls** file

/var/ct/IW/log/mc/default

Location of any errors found in the modified **ctrmc.acls** file

ctrmc.rio File

Purpose

Adjusts reporting intervals for resource dynamic attributes.

Description

To adjust the reporting intervals for resource dynamic attributes that are defined in a class definition file, you can create a *reporting interval override file* called **ctrmc.rio**. A *reporting interval* is the amount of time between a resource manager's sampling of values. You can set reporting intervals for all classes, a single class, or a single attribute of a class. Information in the **ctrmc.rio** file applies only to resource dynamic attributes that have reporting intervals, which have a variable type of **Counter** or **Quantity**.

The **ctrmc.rio** file is a plain text file, in which a line in the file contains two white-space-separated tokens, as follows:

class_name[:attr_name] reporting_interval

The first token is a class name as returned by the **lsrsrc** command, or, a class name followed immediately by a colon, which is followed by an optional resource dynamic attribute name as returned by the **lssrcdef** command. If only a class name is specified, the reporting interval applies to all resource dynamic attributes of the class that have reporting intervals. If a class name and attribute name are specified, the reporting interval applies to the named attribute only, if appropriate. If the attribute does not have a reporting interval, the line is ignored. The second token, the reporting interval, is an unsigned integral value that is interpreted as a number of seconds. If the class name, without any attribute names, is the keyword **ALL**, the reporting interval applies to all dynamic resource attributes of all resource classes. The last specification for an attribute applies.

In the following example:

```
Foo:larry      10
Foo          15
Foo:curly     20
```

the reporting interval would be **15** for **larry** and **20** for **curly**. All other dynamic attributes of the **Foo** class would have a reporting interval of **15**. Blank lines, lines that begin with the number sign (#), and lines that contain unrecognized tokens are ignored.

The reporting interval override file is read by the RMC daemon upon start. If the **refresh -s ctrmc** command is started, the file is reread. In this case, any new reporting intervals apply only to future event registrations.

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) fileset for AIX.

Location

/var/ct/cfg/ctrmc.rio

ctsec.cfg File

Purpose

Provides configuration information about the authentication methods that cluster security services can use for client or server authentication.

Description

The **ctsec.cfg** configuration file provides configuration information about the authentication methods that cluster security services can use for client-server authentication. Each authentication method is handled by a mechanism pluggable module (MPM). Each MPM configuration is defined by a one-line entry in the **ctsec.cfg** file. The entry contains information about:

- The priority of the MPM when cluster security services choose the authentication method for the client-server authentication
- The numeric code of the MPM, which is unique among all of the MPMs in the configuration file
- The mnemonic of the MPM, which is unique among all of the MPMs in the configuration file
- The name of the binary module that implements the function of the MPM
- Miscellaneous flags used by cluster security services mechanism abstract layer (MAL) when handling the MPM

Cluster security services include a default **ctsec.cfg** file in the **/opt/rsct/cfg/** directory. Use the **ctscfg** command to modify a working copy of this configuration file. **ctscfg** does not modify the default configuration file in **/opt/rsct/cfg/**. Instead, **ctscfg** makes a copy (if one does not exist already) of the default **ctsec.cfg** file and copies it to the **/var/ct/cfg/** directory. If a working copy of this file does exist already and there is enough space, the previous version is recorded to **/var/ct/cfg/ctsec.cfg.bak**.

Files

/var/ct/cfg/ctsec.cfg

Working copy of the MAL configuration file

/var/ct/cfg/ctsec.cfg.bak

Backup of the working copy of the MAL configuration file

Implementation specifics

This file is part of the Reliable Scalable Cluster Technology (RSCT) cluster security services. It is shipped as part of the **rsct.core.sec** fileset for AIX.

Location

/opt/rsct/cfg/ctsec.cfg

ctsec_map.global File

Purpose

Associates operating system user identifiers on the local system with network security identifiers for authorization purposes.

Description

RSCT trusted services use the identity mapping definition files **ctsec_map.global** and **ctsec_map.local** to determine whether an RSCT client application's user should be granted access to specific RSCT functions and resources. The file is used to associate security network identifiers that are used by RSCT's cluster security services with user identifiers on the local system. RSCT trusted services use these files to determine what association, if any, exists for the RSCT client, and then use this association while examining the RSCT access controls to determine whether the RSCT client should be granted access.

Two identity mapping definition files can be used:

- The **ctsec_map.global** file contains associations that are to be recognized on all nodes within the cluster configuration
- The **ctsec_map.local** file contains associations that are specific to a particular node

In a cluster configuration, all **ctsec_map.global** files should be the same. Any local system additions that are required for that specific system should be made in the **ctsec_map.local** file.

RSCT provides a default **ctsec_map.global** file in the **/opt/rsct/cfg** directory. Do *not* change this file. If you need to add more associations for the cluster, copy this file to the **/var/ct/cfg** directory. Make any changes to this new file: **/var/ct/cfg/ctsec_map.global**. Any entries that exist in the default **ctsec_map.global** file must exist in the replacement version of the file in the **/var/ct/cfg** directory, or the RSCT trusted services may refuse access to other RSCT trusted services peers. RSCT does not provide a default **ctsec_map.local** file. The administrator can create this file, which must reside in the **/var/ct/cfg** directory as well.

ctsec_map.global and **ctsec_map.local** are ASCII-formatted files that can be viewed and modified using a text editor. Each line in the file constitutes an entry. Blank lines and lines that start with a pound sign (#) are ignored. Each entry is used to either associate a security network identifier with a local operating system user identifier, or to expressly state that no association is allowed for a security network identifier.

Ordering of entries within these files is important. Cluster security services parses the **ctsec_map.global** and **ctsec_map.local** files as follows:

1. If the **/var/ct/cfg/ctsec_map.local** file exists, cluster security services checks for associations in this file
2. If the **/var/ct/cfg/ctsec_map.global** file exists, cluster security services checks for associations in this file
3. Otherwise, cluster security services checks for associations within the **/opt/rsct/cfg/ctsec_map.global**, if this file exists

The first entry that successfully grants or denies an association for a security network identifier in this search path is the one that cluster security services uses. If entries in both the **ctsec_map.global** and **ctsec_map.local** files grant differing associations to the same security network identifier, cluster security services will use the association stated by the entry in the **ctsec_map.local** file. Also, if two entries within the **ctsec_map.global** file grant different associations to the same security network identifier, cluster security services will use the association granted by the entry listed earlier in the **ctsec_map.global** file. You can use the **ctsidmck** command to verify the association rule that is used by cluster security services for specific security network identifiers.

Cluster security services recognizes these characters as reserved: <, >, :, =, !, @, *, and considers these, along with white space characters, as token separators. The wildcard character * is permitted, but should not be used multiple times between other token separator characters. Contents of the identity mapping definition files use the following Backus-Nour format:

```
<mapping_entry> ::= <mechanism_mnemonic> ':' <mapping>  
<mechanism_mnemonic> ::= 'unix', 'krb5'  
<mapping> ::= <explicit_mapping> | <mapping_rule>  
<explicit_mapping> ::= <source_mapping> '=' <local_user_identity>
```

```

| '!' <source_mapping>

<source_mapping> ::= <network_identity> | <match_pattern>'*'
<target_mapping> ::= <mapped_identity> | '*'
<network_identity> ::= <user_name>'@<registry_name>
<user_name> ::= <match_pattern>'*' | '*'
<registry_name> ::= <match_pattern> | '*' | <mpm_defined_reserved_word>
<mpm_defined_reserved_word> ::= '<'<alphanumeric_string>'>'
<mapped_identity> ::= <alphanumeric_string>
<match_pattern> ::= null string | <alphanumeric_string>
<alphanumeric_string> ::= any non-empty array of alphanumeric characters not
                           consisting of the reserved token separator characters

```

An <mpm_defined_reserved_word> is a special instruction to the underlying security mechanism associated with the security network identifier that instructs the mechanism to interpret the identifier in a specific manner. The following reserved words are defined:

<iw> A reserved word for security network identities using the RSCT host-based authentication (HBA) security mechanism. This keyword maps the HBA **root** network identity of the local node to the **root** user. When the cluster security services identity mapping program processes the **ctsec_map.global** file, it replaces the <iw> keyword with the node ID of the node.

<cluster>

A reserved word for security network identities using the HBA security mechanism. The mapping entry is applied to a security network identifier if the identifier is known to originate from any host within the cluster that is currently active for the local node.

<any_cluster>

A reserved word for security network identities using the HBA security mechanism. The mapping entry is applied to a security network identifier if the identifier is known to originate from any host within any cluster that the local node is currently defined. The local node does not need to be active within that cluster when the mapping is applied.

<realm>

A reserved word for security network identities using the Kerberos version 5 mechanism. The mapping entry is applied to a security network identity if the identifier is known to originate within the Kerberos realm that is currently active. See **Restrictions**.

Security

- The default identity mapping definition file **/opt/rsct/cfg/ctsec_map.global** is readable by all system users, but permissions prevent this file from being modified by any system user.
- When creating the override identity mapping definition files **/var/ct/cfg/ctsec_map.global** and **/var/ct/cfg/ctsec_map.local**, make sure that the files can be read by any system user, but that they can only be modified by the root user or other restrictive user identity not granted to normal system users.
- By default, these files reside in locally-mounted file systems. While it is possible to mount the **/var/ct/cfg** directory on a networked file system, this practice is discouraged. If the **/var/ct/cfg/ctsec_map.local** file were to reside in a networked file system, any node with access to that networked directory would assume that these definitions were specific to that node alone when in reality they would be shared.

Restrictions

RSCT does not support the Kerberos version 5 mechanism. Any entries using the mechanism mnemonic `krb5` or the reserved word `<realm>` will not be applied.

Implementation Specifics

These files are part of the Reliable Scalable Cluster Technology (RSCT) cluster security services. The default file is shipped as part of the `rsct.core.sec` fileset for AIX.

Location

`/opt/rsct/cfg/ctsec_map.global`

Contains the default identity mapping definition file.

`/var/ct/cfg/ctsec_map.global`

Contains the replacement for the default global identity mapping definition file. Any entries that exist in the default `ctsec_map.global` file must be replicated in this file, or necessary access required by RSCT trusted services clients will be refused. This file contains identity mapping definitions expected to be recognized by all nodes within the cluster. It is expected that this file will have the same contents for each node within the cluster.

`/var/ct/cfg/ctsec_map.local`

Contains additional identity mapping definitions specific to the local node. This file adds identity mapping definitions to the set recognized for the entire cluster. Entries within this file are applied before entries from the `ctsec_map.global` file. It is expected that the contents of this file will vary from node to node within the cluster, and provide mappings required for clients that access the local node only.

Example

These reserved characters: `<`, `>`, `:`, `=`, `!`, and `@`, are interpreted as token separators, as are white space characters.

Examples of valid identity mapping definition entries:

`unix:zathras@epsilon3.ibm.com=zathras`

This entry grants the association for the RSCT HBA or HBA2 security mechanism identity `zathras@epsilon3.ibm.com` to the local user identifier `zathras`. This entry is not applied to other RSCT HBA or HBA2 identities.

`unix:!zathras@greatmachine.net`

This entry denies any local user identity association for the RSCT HBA or HBA2 identity `zathras@greatmachine.net`. This entry is not applied to other RSCT HBA or HBA2 identities.

`unix:entilzah@cluster=root`

The `cluster` reserved word matches any RSCT HBA or HBA2 identity containing the user name `entilzah` that originates from any host within the currently-active cluster. This grants associations for such RSCT HBA or HBA2 identities as `entilzah@anglashok.ibm.com` and `entilzah@mimbar.ibm.com` to the local user `root` when the local node is active within the cluster that also contains the hosts `anglashok.ibm.com` and `mimbar.ibm.com`. Associations will not be granted for such RSCT HBA or HBA2 identities as `entilzah@whitestar.ibm.com` if the host `whitestar.ibm.com` is not part of the cluster that is currently active.

`unix:entilzah@any_cluster=root`

The `cluster` reserved word matches any RSCT HBA or HBA2 identity containing the user name `entilzah` that originates from any host within the currently-active cluster. This grants associations for RSCT HBA or HBA2 identities such as `entilzah@anglashok.ibm.com` and `entilzah@mimbar.ibm.com` to the local user `root` when the local node is active within the cluster

that also contains the hosts `anglashok.ibm.com` and `mimbar.ibm.com`. Associations will also be granted for RSCT HBA or HBA2 identities such as `entilzah@whitestar.ibm.com` to the local user `root` if the host `whitestar.ibm.com` is part of any cluster known to the local host.

unix:zathras@*=zathras

The * character in this entry matches any RSCT HBA or HBA2 identity that contains the user name `zathras` from any host to the local user identifier `zathras`. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `zathras@greatmachine.net` to the local user identifier `zathras`.

unix:zathras@*.ibm.com=zathras

The * character in this entry will match any RSCT HBA or HBA2 identity that contains the user name `zathras` and a host name ending with an `ibm.com`® network domain to the local user identifier `zathras`. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `zathras@newibm.com` to the local user identifier `zathras`.

unix: *@epsilon3.ibm.com=zathras

The * character in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and associate that client to the local user `zathras`. This will grant associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `draal@epsilon3.ibm.com` to the local user identifier `zathras`.

unix: *@epsilon3.ibm.com=*

The * characters in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and associate that client to the local user whose name matches the user name from the security network identifier. This will grant associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` to the local user `zathras` and `draal@epsilon3.ibm.com` to the local user identifier `draal`.

unix:!*@epsilon3.ibm.com

The * characters in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and deny any association for that client to any local user. This will deny associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `draal@epsilon3.ibm.com`, but will not deny associations for the UNIX HBA network identifier `zathras@greatmachine.net`.

unix: *@*=*

The * characters in this entry matches any RSCT HBA or HBA2 identity from any host and associate that client to the local user whose name matches the user name from the security network identifier. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` to the local user `zathras` and `entilzah@anglashok.ibm.com` to the local user identifier `entilzah`.

Examples of identity mapping definition entries that are not valid:

***:zathras@epsilon3.ibm.com=zathras**

The security mechanism cannot be determined. Each entry must explicitly name a security mechanism that needs to be applied to interpret the entry.

unix:zathras@epsilon3.ibm.com=z*

The local user identity to use is ambiguous.

unix:zathras@*.ibm.*=zathras

This entry repeats wildcard characters between the token separators @ and =, which makes the entry ambiguous.

unix: *athra*@epsilon3.ibm.com=zathras

This entry repeats wildcard characters between the token separators : and @, which makes the entry ambiguous.

unix:*=*

The wildcard character * is ambiguous. It cannot be determined if the wildcard character applies to the identity name or the identity location.

ctsec_map.local File

Purpose

Associates operating system user identifiers on the local system with network security identifiers for authorization purposes.

Description

RSCT trusted services use the identity mapping definition files **ctsec_map.global** and **ctsec_map.local** to determine whether an RSCT client application's user should be granted access to specific RSCT functions and resources. The file is used to associate security network identifiers that are used by RSCT's cluster security services with user identifiers on the local system. RSCT trusted services use these files to determine what association, if any, exists for the RSCT client, and then use this association while examining the RSCT access controls to determine whether the RSCT client should be granted access.

Two identity mapping definition files can be used:

- The **ctsec_map.global** file contains associations that are to be recognized on all nodes within the cluster configuration
- The **ctsec_map.local** file contains associations that are specific to a particular node

In a cluster configuration, all **ctsec_map.global** files should be the same. Any local system additions that are required for that specific system should be made in the **ctsec_map.local** file.

RSCT provides a default **ctsec_map.global** file in the **/opt/rsct/cfg** directory. Do *not* change this file. If you need to add more associations for the cluster, copy this file to the **/var/ct/cfg** directory. Make any changes to this new file: **/var/ct/cfg/ctsec_map.global**. Any entries that exist in the default **ctsec_map.global** file must exist in the replacement version of the file in the **/var/ct/cfg** directory, or the RSCT trusted services may refuse access to other RSCT trusted services peers. RSCT does not provide a default **ctsec_map.local** file. The administrator can create this file, which must reside in the **/var/ct/cfg** directory as well.

ctsec_map.global and **ctsec_map.local** are ASCII-formatted files that can be viewed and modified using a text editor. Each line in the file constitutes an entry. Blank lines and lines that start with a pound sign (#) are ignored. Each entry is used to either associate a security network identifier with a local operating system user identifier, or to expressly state that no association is allowed for a security network identifier.

Ordering of entries within these files is important. Cluster security services parses the **ctsec_map.global** and **ctsec_map.local** files as follows:

1. If the **/var/ct/cfg/ctsec_map.local** file exists, cluster security services checks for associations in this file
2. If the **/var/ct/cfg/ctsec_map.global** file exists, cluster security services checks for associations in this file
3. Otherwise, cluster security services checks for associations within the **/opt/rsct/cfg/ctsec_map.global**, if this file exists

The first entry that successfully grants or denies an association for a security network identifier in this search path is the one that cluster security services uses. If entries in both the **ctsec_map.global** and **ctsec_map.local** files grant differing associations to the same security network identifier, cluster security services will use the association stated by the entry in the **ctsec_map.local** file. Also, if two entries within the **ctsec_map.global** file grant different associations to the same security network identifier, cluster security services will use the association granted by the entry listed earlier in the **ctsec_map.global** file. You can use the **ctsidmck** command to verify the association rule that is used by cluster security services for specific security network identifiers.

Cluster security services recognizes these characters as reserved: <, >, :, =, !, @, *, and considers these, along with white space characters, as token separators. The wildcard character * is permitted, but should not be used multiple times between other token separator characters. Contents of the identity mapping definition files use the following Backus-Nour format:

```
<mapping_entry> ::= <mechanism_mnemonic> ':' <mapping>>  
<mechanism_mnemonic> ::= 'unix', 'krb5'  
<mapping> ::= <explicit_mapping> | <mapping_rule>  
<explicit_mapping> ::= <source_mapping> '=' <local_user_identity>  
    | '!' <source_mapping>  
<source_mapping> ::= <network_identity> | <match_pattern>'*'  
<target_mapping> ::= <mapped_identity> | '*'  
<network_identity> ::= <user_name> '@' <registry_name>  
<user_name> ::= <match_pattern>'*' | '*'  
<registry_name> ::= <match_pattern> | '*' | <mpm_defined_reserved_word>  
<mpm_defined_reserved_word> ::= '<'<alphanumeric_string>'>'  
<mapped_identity> ::= <alphanumeric_string>  
<match_pattern> ::= null string | <alphanumeric_string>  
<alphanumeric_string> ::= any non-empty array of alphanumeric characters not  
    consisting of the reserved token separator characters
```

An <mpm_defined_reserved_word> is a special instruction to the underlying security mechanism associated with the security network identifier that instructs the mechanism to interpret the identifier in a specific manner. The following reserved words are defined:

<iw> A reserved word for security network identities using the RSCT host-based authentication (HBA) security mechanism. This keyword maps the HBA **root** network identity of the local node to the **root** user. When the cluster security services identity mapping program processes the **ctsec_map.global** file, it replaces the **<iw>** keyword with the node ID of the node.

<cluster>

A reserved word for security network identities using the HBA security mechanism. The mapping entry is applied to a security network identifier if the identifier is known to originate from any host within the cluster that is currently active for the local node.

<any_cluster>

A reserved word for security network identities using the HBA security mechanism. The mapping entry is applied to a security network identifier if the identifier is known to originate from any host within any cluster that the local node is currently defined. The local node does not need to be active within that cluster when the mapping is applied.

<realm>

A reserved word for security network identities using the Kerberos version 5 mechanism. The mapping entry is applied to a security network identity if the identifier is known to originate within the Kerberos realm that is currently active. See **Restrictions**.

Security

- The default identity mapping definition file **/opt/rsct/cfg/ctsec_map.global** is readable by all system users, but permissions prevent this file from being modified by any system user.

- When creating the override identity mapping definition files **/var/ct/cfg/ctsec_map.global** and **/var/ct/cfg/ctsec_map.local**, make sure that the files can be read by any system user, but that they can only be modified by the root user or other restrictive user identity not granted to normal system users.
- By default, these files reside in locally-mounted file systems. While it is possible to mount the **/var/ct/cfg** directory on a networked file system, this practice is discouraged. If the **/var/ct/cfg/ctsec_map.local** file were to reside in a networked file system, any node with access to that networked directory would assume that these definitions were specific to that node alone when in reality they would be shared.

Restrictions

RSCT does not support the Kerberos version 5 mechanism. Any entries using the mechanism mnemonic **krb5** or the reserved word **<realm>** will not be applied.

Implementation Specifics

These files are part of the Reliable Scalable Cluster Technology (RSCT) cluster security services. The default file is shipped as part of the **rsct.core.sec** fileset for AIX.

Location

/opt/rsct/cfg/ctsec_map.global

Contains the default identity mapping definition file.

/var/ct/cfg/ctsec_map.global

Contains the replacement for the default global identity mapping definition file. Any entries that exist in the default **ctsec_map.global** file must be replicated in this file, or necessary access required by RSCT trusted services clients will be refused. This file contains identity mapping definitions expected to be recognized by all nodes within the cluster. It is expected that this file will have the same contents for each node within the cluster.

/var/ct/cfg/ctsec_map.local

Contains additional identity mapping definitions specific to the local node. This file adds identity mapping definitions to the set recognized for the entire cluster. Entries within this file are applied before entries from the **ctsec_map.global** file. It is expected that the contents of this file will vary from node to node within the cluster, and provide mappings required for clients that access the local node only.

Example

These reserved characters: **<**, **>**, **:**, **=**, **!**, and **@**, are interpreted as token separators, as are white space characters.

Examples of valid identity mapping definition entries:

unix:zathras@epsilon3.ibm.com=zathras

This entry grants the association for the RSCT HBA or HBA2 security mechanism identity **zathras@epsilon3.ibm.com** to the local user identifier **zathras**. This entry is not applied to other RSCT HBA or HBA2 identities.

unix:!zathras@greatmachine.net

This entry denies any local user identity association for the RSCT HBA or HBA2 identity **zathras@greatmachine.net**. This entry is not applied to other RSCT HBA or HBA2 identities.

unix:entilzah@cluster=root

The **cluster** reserved word matches any RSCT HBA or HBA2 identity containing the user name **entilzah** that originates from any host within the currently-active cluster. This grants associations for such RSCT HBA or HBA2 identities as **entilzah@anglashok.ibm.com** and **entilzah@mimbar.ibm.com** to the local user **root** when the local node is active within the cluster

that also contains the hosts `anglashok.ibm.com` and `mimbar.ibm.com`. Associations will not be granted for such RSCT HBA or HBA2 identities as `entilzah@whitestar.ibm.com` if the host `whitestar.ibm.com` is not part of the cluster that is currently active.

unix:entilzah@any_cluster=root

The `cluster` reserved word matches any RSCT HBA or HBA2 identity containing the user name `entilzah` that originates from any host within the currently-active cluster. This grants associations for RSCT HBA or HBA2 identities such as `entilzah@anglashok.ibm.com` and `entilzah@mimbar.ibm.com` to the local user `root` when the local node is active within the cluster that also contains the hosts `anglashok.ibm.com` and `mimbar.ibm.com`. Associations will also be granted for RSCT HBA or HBA2 identities such as `entilzah@whitestar.ibm.com` to the local user `root` if the host `whitestar.ibm.com` is part of any cluster known to the local host.

unix:zathras@*=zathras

The `*` character in this entry matches any RSCT HBA or HBA2 identity that contains the user name `zathras` from any host to the local user identifier `zathras`. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `zathras@greatmachine.net` to the local user identifier `zathras`.

unix:zathras@*.ibm.com=zathras

The `*` character in this entry will match any RSCT HBA or HBA2 identity that contains the user name `zathras` and a host name ending with an `.ibm.com` network domain to the local user identifier `zathras`. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `zathras@newibm.com` to the local user identifier `zathras`.

unix: *@epsilon3.ibm.com=zathras

The `*` character in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and associate that client to the local user `zathras`. This will grant associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `draal@epsilon3.ibm.com` to the local user identifier `zathras`.

unix: *@epsilon3.ibm.com=*

The `*` characters in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and associate that client to the local user whose name matches the user name from the security network identifier. This will grant associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` to the local user `zathras` and `draal@epsilon3.ibm.com` to the local user identifier `draal`.

unix:!*@epsilon3.ibm.com

The `*` characters in this entry matches any RSCT HBA or HBA2 identity from the host `epsilon3.ibm.com` and deny any association for that client to any local user. This will deny associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` and `draal@epsilon3.ibm.com`, but will not deny associations for the UNIX HBA network identifier `zathras@greatmachine.net`.

unix: *@*=*

The `*` characters in this entry matches any RSCT HBA or HBA2 identity from any host and associate that client to the local user whose name matches the user name from the security network identifier. This grants associations for RSCT HBA or HBA2 identities such as `zathras@epsilon3.ibm.com` to the local user `zathras` and `entilzah@anglashok.ibm.com` to the local user identifier `entilzah`.

Examples of identity mapping definition entries that are not valid:

***:zathras@epsilon3.ibm.com=zathras**

The security mechanism cannot be determined. Each entry must explicitly name a security mechanism that needs to be applied to interpret the entry.

unix:zathras@epsilon3.ibm.com=z*

The local user identity to use is ambiguous.

unix:zathras@*.ibm.*=zathras

This entry repeats wildcard characters between the token separators @ and =, which makes the entry ambiguous.

unix:athra*@epsilon3.ibm.com=zathras

This entry repeats wildcard characters between the token separators : and @, which makes the entry ambiguous.

unix:*=*

The wildcard character * is ambiguous. It cannot be determined if the wildcard character applies to the identity name or the identity location.

Data (D.*) Files for BNU

Purpose

Contain data to be sent to remote systems.

Description

Data (D.*) files contain the data to be sent to remote systems by the Basic Networking Utilities (BNU) **uucico** daemon. The full path name of a data file is a form of the following:

/var/spool/uucp/SystemName/D.SystemNamexxx###

where the *SystemName* directory and the *SystemName* portion of the file name indicate the name of the remote system. The xxxx### notation is the hexadecimal sequence number of the command (C.*) file associated with that data file, for example: D.venus471af8.

After a set period of time (specified by the **uusched** daemon), the **uucico** daemon transfers the data file to the designated system. It places the original data file in a subdirectory of the BNU spooling directory named **/var/spool/uucp/SystemName**, where the *SystemName* directory is named for the computer that is transmitting the file, and creates a temporary (TM.*) file to hold the original data file.

After receiving the entire file, the BNU program takes one of the three following actions:

- If the file was sent with the **uucp** command and there were no transfer problems, the program immediately renames the TM.* file with the appropriate data file name, such as D.venus471af8, and sends it to the specified destination.
- If the file was sent with the **uuto** command, the BNU program also renames the temporary data file with the appropriate D.* file name. The program then places the data file in the **/var/spool/uucppublic** public directory, where the user receives the data file and handles it with one of the **uupick** command options.
- If there were transfer problems (such as a failed login or an unavailable device), the temporary data file remains in the spooling subdirectory. The **uudemon.cleanu** command, a shell procedure, removes these files automatically at specified intervals. They can also be removed manually.

Files

| Item | Description |
|--|--|
| /etc/uucp/Systems | Describes accessible remote systems. |
| /var/spool/uucp/ <i>SystemName</i> directory | Contains BNU command, data, and execute files. |
| /var/spool/uucp/ <i>SystemName</i> /C.* | Contains instructions for file transfers. |
| /var/spool/uucp/ <i>SystemName</i> /TM.* | Stores data files temporarily after they have been transferred to a remote system. |
| /var/spool/uucppublic/* directory | Contains files that the BNU program has transferred. |

/dev/hty File

Purpose

Defines the Network Terminal Accelerator adapter tty interface.

Description

The */dev/hty** device files define, for the host computer, the interface-to-host adapter communication channels. For each I/O device connected to the host computer through a host adapter, there must be a */dev/hty** device file created to allow communication between the host computer and the I/O device.

To allow for future expansion, there may be more */dev/hty** files than actual physical devices connected through the host adapter.

The hty ports are functionally equivalent to */dev/tty** device files. The minor number corresponds to the channel number, as defined in the **hty_config** file.

Files

| Item | Description |
|------------------|---------------------------------|
| <i>/dev/hty</i> | Specifies the path to the file. |
| <i>/dev/rhp*</i> | Adapter raw device. |

Related reference:

“/dev/rhp File”

/dev/rhp File

Purpose

Defines the Network Terminal Accelerator adapter raw interface.

Description

The */dev/rhp** device files define, for the host computer, the interface to the host adapters. For each host adapter installed in the host computer, there must be a */dev/rhp** device file created in order to allow communication between the host computer and the host adapter board.

The */dev/rhp** device file corresponding to a respective host adapter is used as an argument in many of the utility programs.

Files

| Item | Description |
|----------|---|
| /dev/rhp | Specifies the path to the file |
| /dev/hty | Defines the Network Terminal Accelerator adapter tty interface. |

Related reference:

DHCP Client Configuration File

Purpose

Default configuration information for the Dynamic Host Configuration Protocol (DHCP) client program (dhpcd).

Description

The **dhpcd** configuration file contains entries for logging information, requested options, interfaces to configure, and other items.

Following are the formats for the data in the configuration file.

Comment line

The # character means that there is a comment from that point to the end of the line.

numLogFile n

Specifies the number of log files. If 0 is specified, no log file will be maintained and no log message is displayed anywhere. *n* is the maximum number of log files maintained as the size of the most recent log file reaches its maximum size and a new log file is created.

logFileSize n

Maximum size of a log file. When the size of the most recent log file reaches this value, it is renamed and a new log file is created. *n* is measured in kilobytes(KB).

logFileName filename

Name and path of the most recent log file. Less recent log files have the number 1 to (*n* - 1) appended to their names; the larger the number, the older the file.

logItem <option name>

One item that will be logged. Multiple of these lines are allowed. This allows for the specified logging level to be turned on. The following are option names:

SYSERR

System error, at the interface to the platform

OBJERR

Object error, in between objects in the process

PROTERR

Protocol error, between client and server

WARNING

Warning, worth attention from the user

EVENT

Event occurred to the process

ACTION

Action taken by the process

INFO

Information that might be useful

ACNTING

Who was served, and when

TRACE

Code flow, for debugging.

interface <ifName>

The interface to configure DHCP on. This may be the interface that is to be configured. Multiples of these are allowed. There is a special entry, any. This tells the DHCP client to configure the first one it finds and completes successfully. If the any option is used, there should not be any other interface specified. The interface statement may be immediately followed by a pair of curly braces, in which the options requested for this interface can be specified. Options requested within interface curly braces apply only to this interface. See DHCP Server Configuration File for a list of options and formats.

clientid <MAC | HOSTNAME>

Specifies the client id to use in all communication with the server. MAC denotes that the hardware address for the particular interface should be used as the client id. HOSTNAME denotes that the domain host name should be used as the client id. The default is MAC.

sniffer <exec string>

Specifies a string enclosed in quotes, indicating a program to execute to detect hardware failure/recovery for an interface. The **dhcp** client will look for signal 23(SIGIO) to indicate that the network interface is up and signal 16(SIGURG) to indicate that the network interface is down.

option <code> [<value>] [<exec <string>>]

Specifies an option requested by this client. Its scope is determined by whether it is inside a set of curly braces for a particular interface, or if it is outside all curly braces. If outside, it applies to all interfaces. code is the option code of the option requested. value is the requested value for that option. This value is passed to the server with the option. The value is not required. The keyword exec denotes a string following which should be executed if this option is returned by the server. This string is expected to be an executable shell script or program. An "%s" may be included in the string. If present, the value returned by the server will be provided in ascii.

vendor

Specifies the special syntax for the specification of the vendor extensions field. It is followed by a set of curly braces. Inside the curly braces, the options and values for the vendor extensions field are specified. The exec string on an option inside the vendor extensions options is not valid. It is ignored.

reject <code>

Specifies that if this option code is returned by the server, this option should be ignored by the client. Its value should not be used.

otherOptions <accept | reject>

Specifies how all other options should be handled by the client. This refers to any options not specifically requested with an "option" statement or rejected with a "reject" statement. The default is that all options are accepted.

updateDNS <string>

A string enclosed in quotes, indicating a program to execute to update the DNS server with the new inverse mapping for the IP address and names served by **dhcp**. This string should include four %'s to indicate the placement of the following information from the **dhcp** client:

hostname

Value of option 12. The value returned by the **dhcp** server is used, if one is supplied. Else, if the client specified a value in *this* file, the client-requested value is used. If neither the client specified a requested hostname nor the server supplied one, this exec string will not be executed.

domainname

Value of option 15. The value returned by the **dhcp** server is used, if one is supplied.

Else, if the client specified a value in *this* file, the client-requested value is used. If neither the client specified a requested hostname nor the server supplied one, a null string (" ") will be supplied by **dhcp**. Therefore, this value is optional.

Ip Address

IP address leased to this client by the server. The string is supplied in dotted notation, for example, 9.2.23.43.

leasetime

Lease time granted by the server. This string is a decimal number representing the number of seconds of the lease.

These values are output by **dhcp** in this order:

```
hostname domainname Ip Address leasetime
```

A script **/usr/sbin/dhcpaction** has been provided with this function, as well as actions to help NIM interact with DHCP clients. Run the script as follows:

```
/usr/sbin/dhcpaction hostname domainname ipaddress  
leasetime < A | PTR | BOTH | NONE > NONIM
```

The first four parameters are what will be used to update the DNS server. The fifth parameter tells **dhcpaction** to update the A record, the PTR record, or both, or none. The options are A, PTR, BOTH, NONE. The sixth parameter is used to tell servers that NIM is being used, and processing needs to be done when a client changes address. The options for this are NIM and NONIM. On clients, this must be set to NONIM.

An example follows:

```
updateDNS "/usr/sbin/dhcpaction %s %s %s %s %s PTR  
NONIM 2>&1 >>/tmp/updns.out"
```

initTimeout <timeout>

Specifies the timeout value in minutes. If the **dhcp** client fails to configure an address for an interface within this timeout value, it stops making further attempts. This entry applies to systems running the AIX operating system.

This file is part of TCP/IP in Network Support Facilities in Base Operating System (BOS) Runtime.

Example

This example tells the **dhcpcd** daemon to use log files of a maximum of 100Kb in size and at most four of them.

The base name for the log files is **/usr/tmp/dhcpsd.log**. The user also would like to only log four of the nine possible log entry types. The user also specified a string to use for updating the Dynamic Domain Name Server. The user also specified that the clientId to the server should be based on the mac-address of the interface adapter that is trying to be configured. The user also specified that all options should be accepted and instantiated (**otheroptions accept**), except for option 9 (reject 9).

The options the user specified were the domain (option 15), but since this option is global to the interface keywords, it applies to both interfaces.

Inside each interface, the hostname is specified with option 12.

```
numLogFile 4  
logFileSize 100  
logFileName /usr/tmp/dhcpsd.log  
logItem SYSERR  
logItem OBJERR  
logItem PROTERR  
logItem TRACE  
updateDNS "nsupdate -h% -d% -i% %s"
```

```

clientid MAC
otheroptions accept
reject 9
option 15 "austin.ibm.com"
interface en0
{
    option 12 "e-chisos"
}
interface tr0
{
    option 12 "t-chisos"
}

```

"DHCP Server Configuration File"

Related information:

dhpcd command

TCP/IP address and parameter Assignment - Dynamic Host Configuration Protocol

DHCP Server Configuration File

Purpose

Defines default configuration information for the Dynamic Host Configuration Protocol (DHCP) server program (dhcpsd).

Description

The dhcpsd configuration file contains entries for logging information, options to return, machines to configure, and other items.

Following are the formats for the data in the configuration file.

Comment line

The # character means that there is a comment from that point to the end of the line.

"Name of Resource" "<Keyword> <value> <value> ..."

The ## characters denote a named resource. This is used by the **dhcpsconf** program to allow the user to create specific resources. The data is stored in the server file so that it can be read in with the configuration file and displayed as the name and not the value in the viewing window of **dhcpsconf**.

The format of the ## line is a quoted string that is the name of the resource followed by a double-quoted string representing a valid possible line for a configuration file. The second quoted string should be syntactically correct for a line in a DHCP server configuration file. The keyword can only be option, network, subnet, class, and client.

"DHCP Server" "Any line from a server file"

The ### characters denote a server configuration file. This allows for multiple server files to be saved in one file. The **dhcpsconf** program uses this to present multiple server datasets in a master. This would be useful, if you were to define a network with 10 servers and wanted to save all the server information in one file and maintain a default server. The default server would go into the master file, and the servers would be saved in the master file with the ### characters.

The **dhcpsconf** program has a function that allows you to create a specific server configuration out of the master file.

numLogFile n

Specifies the number of log files. If 0 is specified, no log file will be maintained and no log message is displayed anywhere. n is the maximum number of log files maintained as the size of the most recent log file reaches its maximum size and a new log file is created.

logFileSize n

Maximum size of a log file. When the size of the most recent log file reaches this value, it is renamed and a new log file is created. *n* is measured in kilobytes(KB).

logFileName filename

Name and path of the most recent log file. Less recent log files have the number 1 to (n - 1) appended to their names; the larger the number, the older the file.

logItem <option name>

One item that will be logged. Multiple of these lines are allowed. This allows for the specified logging level to be turned on. The following are option names:

SYSERR

System error, at the interface to the platform

OBJERR

Object error, in between objects in the process

PROTERR

Protocol error, between client and server

WARNING

Warning, worth attention from the user

EVENT

Event occurred to the process

ACTION

Action taken by the process

INFO Information that might be useful**ACNTING**

Who was served, and when

TRACE

Code flow, for debugging.

clientrecorddb <filename>

This is the path to a file to substitute for /etc/dhcps.cr. Configurations that support a large number of addresses should set **clientrecorddb** and **addressrecorddb** database files in a file system with substantial free space.

addressrecorddb <filename>

This is the path to a file to substitute for /etc/dhcps.ar.

network <Network address> [<Subnet Mask>|<range>]

Specifies one network administered by this server. Network address is the address of this network. This address is specified in the dotted notation (for example, 9.0.0.0, 128.81.0.0, or 192.81.20.0). Full four-byte value should be specified (for example, 9, 128.81, or 192.81.20 is not legal).

Network address may optionally be followed by the subnet mask, a range, or nothing.

If a subnet mask is specified, one or more subnet statements should appear in the succeeding lines within a pair of curly braces. The subnet mask may be specified either in the dotted notation (for example, 255.255.255.128) or as a number indicating the number of 1 bits in the mask (for example, 25, which is equivalent to 255.255.255.128). The means that a network is not a collection of all subnet for a network, but all subnets with the same length subnet for that network "prefix."

If a range is specified, it determines, within the network, the range of hosts that are administered by this server, and it implies that there is no subnetting. A range is specified by the host

addresses, in the dotted notation, at the lower end and the higher end of the range, respectively, separated by a hyphen with no spaces before or after it (for example, 192.81.20.1-129.81.20.128). A range must encompass all addresses to be administered because multiple network statements to define the same network are not allowed. Use the "client" statement to exclude any addresses in the range that the server should not administer.

If nothing is specified after Network address, all hosts in that network are administered by this server.

A network statement may be immediately followed by a pair of curly braces, in which parameters (for example, options) particular to this network can be specified.

subnet <Subnet address> [<range>]

One or more subnet statements are enclosed by a pair of curly braces that immediately follows a network statement with subnet mask. A subnet statement specifies one subnet within that network.

Subnet address is the address of this subnet. This address is specified in the dotted notation (for example, 9.17.32.0 or 128.81.22.0).

Subnet address may be followed by a range or nothing.

If a range is specified, it determines, within the subnet, the range of hosts that are administered by this server. A range is specified by the host addresses, in the dotted notation, at the lower end and the higher end of the range, respectively, separated by a hyphen with no spaces before or after it. A range must encompass all addresses to be administered since multiple subnet statements to define the same subnet are not allowed. Use the "client" statement to exclude any addresses in the range which the server should not administer.

If nothing is specified after Subnet address, all hosts in that subnet are administered by this server.

The ranges in two servers administering the same subnet cannot overlap. Otherwise, two hosts may be assigned the same address.

A subnet statement may be immediately followed by a pair of curly braces, in which parameters (for example, options) particular to this subnet can be specified.

class <class_name> [<range>]

Specifies a class. The class name is a simple ascii string. A class's scope is determined by the curly braces in which it is enclosed. If it is outside all curly braces, then its scope is the entire file.

A class name may be followed by a range or nothing. If a range of Ip Addresses is specified, then only addresses in that range will be assigned to clients who request this class. Note that clients who request this class, for which the subnet does not match the range, will not be processed. Bad addresses will not be given out by the server. If an address range is not specified, then addresses will be given to clients using the usual rules of assignment (by network clauses).

The class statement may be immediately followed by a pair of curly braces, in which the options particular to this class can be specified. A class may be defined within the curly braces of a subnet, but a subnet may not be defined within the curly braces of a class.

Options set up in the network or subnet containing a class definition will also apply to the class.

client <id_type> <id_value> <address>

Specifies a definition of client/address processing.

<id_type> is 0 for a string, otherwise it is one of the hardware types defined in RFC 1340 (for example, 6 for IEEE 802 networks.)

<id_value> is a character string for <id_type>=0. Typically, this would be a domain name. For a non-zero <id_type>, the <id_value> is a hexadecimal string representing the hardware address of the client.

Note: An <id_type> of 0 and an <id_value> of 0 indicates that the <address> specified should not be distributed by this server.

The <address> can be the string "none" to indicate that the client with <id_type> and <id_value> should not be serviced by this server. The <address> can be the string "any" to indicate that the server should choose an appropriate address for this client. The <address> can be an internet address in dotted notation (for example, 9.2.15.82). This will be the Ip address given to the particular client specified by <id_type> and <id_value>. As mentioned above, an <id_type> of 0 and an <id_value> of 0 indicates that the <address> specified should not be distributed by this server.

Note: If a client is configured in this way on the server, then any class information requested by the client will be ignored. No class-specific information will be processed for these clients.

The client statement may be immediately followed by a pair of curly braces, in which the options particular to this client can be specified.

A client statement with an address specified that is not part of the address pool specified in a network/subnet elsewhere in this file must contain the subnet mask option(1). For all other clients, the server will compute the subnet mask option to send the client based on the network/subnet definitions.

Note: All clients inherit all globally defined options. A client defined in a network scope will inherit options defined for that network. A client defined in a subnet scope, will inherit options defined for that subnet and encompassing network.

A class definition inside a client scope is not allowed.

The client statement may be used to configure **bootp** clients. To do this, specify all the **bootp** options using the option syntax defined below. In addition, specify an infinite lease time in the client scope with "option 51 0xffffffff". DHCP options will not be served to the **bootp** client.

nakoutofrange <option>

Specifies the behavior of the DHCP server when a client requests an IP address that this server does not administer.

When a DHCP client moves from one DHCP domain to a new DHCP domain, the client requests its previous IP address from the new DHCP server. By default, the DHCP server ignores such requests without sending a refusal (DHCP NAK). The **nakoutofrange** policy in the AIX DHCP server enables the DHCP administrator to force the server to send refusals to clients in such situations, and to force the clients to request new addresses and configurations.

You can place the **nakoutofrange** option either inside a subnet scope or in the global scope. Each option and its placement have specific implications to the behavior of the DHCP server. The following options are available:

none This is the default setting when the **nakoutofrange** keyword is not present. A DHCP server sends a DHCP NAK response when a client asks for an address that the server controls and that the client cannot use. For example, a client requests an address that another client is using.

Note: To use a policy other than **none** in the global area, you must understand the network topology and ensure that clients of the DHCP server can reach the DHCP server from any network access point.

insubnet

If a client requests an address that matches the subnet from which the client is broadcasting, but the address does not fall within the controlled IP address ranges of that subnet, the DHCP server sends a DHCP NAK response to the client.

Note: Do not use this option when multiple DHCP servers are controlling separate IP address ranges on the same subnet, unless every access point to the subnet can only reach one of the DHCP servers.

notinsubnet

The DHCP server sends a DHCP NAK response to a client that is requesting an address that does not match the subnet from which the client is broadcasting. When this option is placed outside the subnet scope, the DHCP NAK response is sent when the client's broadcast is received from a subnet that is not controlled by the server.

Note: When this option is placed inside the subnet scope, it should be used when there are no other logical subnets on the client's network segment that are administered through any DHCP server.

- both** The DHCP server sends a DHCP NAK response to a client that is requesting an address that the server cannot assign to the client. Placing this option inside a subnet scope combines the implications of placing the **notinsubnet** option and the **insubnet** option inside the subnet scope. Place this option inside a subnet scope when the configured DHCP server is the only DHCP server capable of assigning an address to a client broadcasting from any of the network access points on the subnet. This option should be placed globally only when the configured DHCP server is the only reachable DHCP server from any of the network access points.

The following is an example of the **nakoutofrange** option:

```
nakoutofrange none
subnet 192.1.1.0 255.255.255.0 192.1.1.5-192.1.1.254
{
    nakoutofrange both
    # ... options ...
}
subnet 12.1.10.0 255.255.255.0 12.1.10.5-12.1.10.150
{
    # another server controls addresses 12.1.10.151-12.1.10.254
    nakoutofrange notinsubnet
    # ... options ...
}
```

Note: A typical configuration is to use the **both** option inside all subnet scopes and to leave the default **none** option enforced in the global scope.

option <code> <value>

This parameter specifies the value of an option defined in "DHCP Options and BOOTP Vendor Extensions" (RFC 1533) and supported by this server.

An option is specified by the "option" keyword followed by the option code of this option and its data field, in a single line. One or more of this parameter may be specified.

The scope within which an option applies is delimited by a pair of curly braces ({, }) surrounding this parameter.

Two or more options with the same option code may be specified. Their data fields are concatenated in a single option in a packet generated by the server if the options have the same scope or one's scope includes that of another.

Some of the defined options do not need to be specified by this parameter. These options are either mandated by the protocol or this implementation to be present in proper packets, or only generated by a client. These options are:

| Option Code | Name |
|-------------|----------------------------|
| 0 | Pad Option |
| 255 | End Option |
| 1 | Subnet Mask |
| 50 | Request IP Address |
| 51 | IP Address Lease Time |
| 52 | Option Overload |
| 53 | DHCP Message Type |
| 54 | Server Identifier |
| 55 | Parameter Request List |
| 57 | Maximum DHCP Message Size |
| 58 | Renewal (T1) Time Value |
| 59 | Rebinding (T2) Time Value |
| 60 | Class identifier of client |
| 61 | Client identifier |

The other options may be specified by this parameter.

When specifying an option, its data field takes one of the following formats:

IP Address

xxx.xxx.xxx.xxx

IP Addresses

[xxx.xxx.xxx.xxx ...]

IP Address Pair

[ip address:ip address]

IP Address Pairs

[[ip address:ip address] ...]

Boolean

[0, 1]

Byte

[-128, 127]

Unsigned Byte

[0, 255]

Unsigned Bytes

[[0, 255] [0, 255] ...]

Short

[-32768, 32767]

Unsigned Short

[0, 65535]

Unsigned Shorts

[[0, 65535] [0, 65536]]

Long

[-2147483648, 2147483647]

Unsigned Long

[0, 4294967295]

String

"Value Here"

Note: All IP addresses are specified in dotted-decimal form.

Each of the defined options is listed below by its code and name, followed by the format of its data field. These are specified in latest Vendor Extensions RFC.

| Code | Name | Data Field Format and Notes |
|-------------|---------------------------------|------------------------------------|
| 0 | Pad Option | No need to specify |
| 255 | End Option | No need to specify |
| 1 | Subnet Mask | Unsigned Long |
| 2 | Time Offset | Long |
| 3 | Router Option | IP Addresses |
| 4 | Timer Server Option | IP Addresses |
| 5 | Name Server Option | IP Addresses |
| 6 | Domain Name Server Option | IP Addresses |
| 7 | Log Server Option | IP Addresses |
| 8 | Cookie Server Option | IP Addresses |
| 9 | LPR Server Option | IP Addresses |
| 10 | Impress Server Option | IP Addresses |
| 11 | Resource Location Server Option | IP Addresses |
| 12 | Host Name Option | String |
| 13 | Boot File Size Option | Unsigned Short |
| 14 | Merit Dump File | String |
| 15 | Domain Name | String |
| 16 | Swap Server | IP Address |
| 17 | Root Path | String |
| 18 | Extensions Path | String |

IP Layer Parameters per Host

| Code | Name | Data Field Format and Notes |
|-------------|--|------------------------------------|
| 19 | IP Forwarding Enable/Disable Option | Boolean |
| 20 | Non-local Source Routing Enable/Disable Option | Boolean |
| 21 | Policy Filter Option | IP Address Pairs |
| 22 | Maximum Datagram Reassembly Size | Unsigned Short |
| 23 | Default IP Time-to-live | Unsigned Byte |
| 24 | Path MTU Aging Timeout Option | Unsigned Long |
| 25 | Path MTU Plateau Table | Unsigned Shorts |

IP Layer Parameters per Interface

| Code | Name | Data Field Format and Notes |
|-------------|------------------------------------|------------------------------------|
| 26 | Interface MTU Option | Unsigned Short |
| 27 | All Subnets are Local Option | Boolean |
| 28 | Broadcast Address Option | IP Address |
| 29 | Perform Mask Discovery Option | Boolean |
| 30 | Mask Supplier Option | Boolean |
| 31 | Perform Router Discovery Option | Boolean |
| 32 | Router Solicitation Address Option | IP Address |
| 33 | Static Route Option | IP Address Pairs |

Link Layer Parameters per Interface

| Code | Name | Data Field Format and Notes |
|------|-------------------------------|-----------------------------|
| 34 | Trailer Encapsulation Option | Boolean |
| 35 | ARP Cache Timeout Option | Unsigned Long |
| 36 | Ethernet Encapsulation Option | Boolean |

TCP Parameters

| Code | Name | Data Field Format and Notes |
|------|-------------------------------|-----------------------------|
| 37 | TCP Default TTL Option | Unsigned Byte |
| 38 | TCP Keepalive Interval Option | Unsigned Long |
| 39 | TCP Keepalive Garbage Option | Boolean |

Application and Service Parameters

| Code | Name | Data Field Format and Notes |
|------|--|-----------------------------|
| 40 | NIS Domain Option | String |
| 41 | NIS Option | IP Addresses |
| 42 | Network Time Protocol Servers Option | IP Addresses |
| 43 | Vendor Specific Information | Unsigned Bytes |
| 44 | NetBIOS over TCP/IP Name Server Option | IP Addresses |
| 45 | NetBIOS over TCP/IP Datagram Distribution Server | IP Addresses |
| 46 | NetBIOS over TCP/IP Node Type Option | Unsigned Byte |
| 47 | NetBIOS over TCP/IP Scope Option | Unsigned Bytes |
| 48 | X Window System Font Server Option | IP Addresses |
| 49 | X Window System Display Manager Option | IP Addresses |

DHCP Extensions

| Code | Name | Data Field Format and Notes |
|------|----------------------------|-----------------------------|
| 50 | Request IP Address | No need to specify |
| 51 | IP Address Lease Time | Unsigned Long |
| 52 | Option Overload | No need to specify |
| 53 | DHCP Message Type | No need to specify |
| 54 | Server Identifier | No need to specify |
| 55 | Parameter Request List | No need to specify |
| 56 | Message | String |
| 57 | Maximum DHCP Message Size | No need to specify |
| 58 | Renewal (T1) Time Value | No need to specify |
| 59 | Rebinding (T2) Time Value | No need to specify |
| 60 | Class Identifier of Client | Generated by client |
| 61 | Client Identifier | Generated by client |

BOOTP Specific Options

| Code | Name | Data Field Format and Notes |
|------|--|-----------------------------|
| sa | Server Address for the BOOTP client to use | IP Address |
| bf | Bootfile for the BOOTP client to use | String |
| hd | Home Directory for the BOOTP client to search for the bootfile | String |

Following is an example of BOOTP specific options:

```
option sa 1.1.2.2
option hd "/vikings/native"
option bf "bootfile.asdg"
```

Other option numbers may be specified, up to a maximum of 255. The options not listed above must be specified with the unsigned byte list type. Following is an example:

```
option 178 01 34 53 # Means place tag 178 with value
0x013553
```

leaseTimeDefault <amount>[<unit>]

Specifies the default lease duration for the leases issued by this server. In the absence of any more specific lease duration (for example, lease duration for specific client(s) or class of clients), the lease duration specified by this parameter takes effect.

The amount is specified by a decimal number. The unit is one of the following (plural is accepted):

- year
- month
- week
- day
- hour
- minute (default if unit is absent)
- second

There is at least one white space in between the amount and unit. Only the first amount following the keyword has effect.

If this parameter is not specified, the default lease duration is one (1) hour.

This parameter should appear outside of any pair of curly braces, for example, it applies to all leases issued by this server.

Note: This keyword only applies to the default for all addresses. To specify a specific lease time for a subnet, network, class or client, use the usual "option 51 value" to specify that lease time (in seconds).

leaseExpireInterval <amount> [<unit>]

Specifies the time interval at which the lease expiration condition is examined, and if a running lease meets such condition, it is expired. The value of this parameter applies to all leases administered by this server.

The amount is specified by a decimal number. The unit is one of the following (plural is accepted):

- year
- month
- week
- day

- hour
- minute (default if unit is absent)
- second

There is at least one white space in between the amount and unit. Only the first amount following the keyword has effect.

If this parameter is not specified, the default interval is one (1) minute.

This parameter should appear outside of any pair of curly braces, for example it applies to all leases issued by this server.

The value of this parameter *should* be in proportion with that of parameter `leaseTimeDefault` so that the expirations of leases are recognized in time.

supportBOOTP [yes | no]

Indicates to the server whether or not to support requests from BOOTP clients.

If yes is specified, the server will support BOOTP clients.

If the value field is not a yes, or the keyword is omitted, the server will not support BOOTP clients.

The scope of this parameter covers all the networks and subnets administered by this server.

If the server previously supported BOOTP clients and has been reconfigured not to support BOOTP clients, the address binding for a BOOTP client established before the reconfiguration, if any, will still be maintained until the time when that BOOTP client sends a request again (when it is rebooting.) At that time, the server will not respond, and the binding will be removed.

supportunlistedClients [yes | no]

Indicates to the server whether or not to support requests from clients that are not specifically configured with their own individual client statements in the server.

If yes is specified, the server will support unlisted clients.

If the value field is anything other than yes, the server will not support unlisted clients.

If this keyword is not found in the file, the server *will* support clients not specifically configured with a client statement.

updateDNS <string>

A string enclosed in quotes, indicating a program to execute to update the DNS server with the new inverse mapping for the IP address and names served by `dhcp`. This string should include four %'s to indicate the placement of the following information from the `dhcp` client:

hostname

Value of option 12. The value returned by the `dhcp` server is used, if one is supplied. Else, if the client specified a value in *this* file, the client-requested value is used. If neither the client specified a requested hostname nor the server supplied one, this exec string will not be executed.

domainname

Value of option 15. The value returned by the `dhcp` server is used, if one is supplied. Else, if the client specified a value in *this* file, the client-requested value is used. If neither the client specified a requested hostname nor the server supplied one, a null string (" ") is supplied by `dhcp`. This may cause the update of address records to fail.

Ip Address

IP address leased to this client by the server. The string is supplied in dotted notation, for example, 9.2.23.43.

leasetime

Lease time granted by the server. This string is a decimal number representing the number of seconds of the lease.

These values are output by **dhcp** in this order:

```
hostname domainname Ip Address leasetime
```

A script **/usr/sbin/dhcpaction** has been provided with this function, as well as actions to help NIM interact with DHCP clients. Run the script as follows:

```
/usr/sbin/dhcpaction hostname domainname ipaddress  
leasetime < A | PTR | BOTH | NONE > < NONIM | NIM >
```

The first four parameters are what will be used to update the DNS server. The fifth parameter tells **dhcpaction** to update the A record, the PTR record, or both, or none. The options are A, PTR, BOTH, NONE. The sixth parameter is used to tell servers that NIM is being used, and processing needs to be done when a client changes address. The options for this are NIM and NONIM.

An example follows:

```
updateDNS "/usr/sbin/dhcpaction %s %s %s %s %s PTR  
NONIM 2>&1 >>/tmp/updns.out"
```

Examples

1. In this example, we are setting up a server with a default lease time of 30 minutes. This means that any address that doesn't explicitly have a lease time set in a network, class, client, or subnet scope, will get 30 minutes. We are also setting the time between server address expiration checks to 3 minutes. This means that every 3 minutes, the server will check to see if an address has expired and mark it as expired. We are also saying the server should accept BOOTP requests and accept any client that matches the normal address assignment scheme. The normal address assignment scheme means that an address and options are assigned based on the network/subnet that the client is on.

We are also setting up two global options that should apply to all clients we serve. We are saying that there is a printer at 10.11.12.13 for everyone to use and the global domain name is **dreampark**. We are defining one network that has subnetting on the first 24 bits.

Thus, the network we are defining has some number of subnets and all the subnets we are specifying in this network scope have netmask of 255.255.255.0. Under that network, we are defining some options for that network and some subnets. The subnets define the actual addresses available for distribution. There are two subnets. Inside the second subnet, there is a class. The class information only applies to hosts on the second subnet that request that class. If that class is asked for the host, it will get two netbios options. If the address is in the first subnet, it will get the options in the subnet clause, which are nothing. If the host is in the second subnet, it will get all the options in the clause for the second subnet. If it also has the class, it will get the class options. If options are repeated with the same scope or a sub-scope, these options are concatenated together and set as one option. All hosts given an address from one of the two subnets will receive the options that are in the network scope.

```
leaseTimeDefault          30 minutes  
leaseExpireInterval      3 minutes  
supportBOOTP              yes  
supportUnlistedClients    yes  
  
option 9                  10.11.12.13          # printer for all  
option 15                 dreampark           # domain  
name  
  
network 9.0.0.0 24  
{  
    subnet 9.2.218.0        9.2.218.1-9.2.218.128  
    subnet 9.67.112.0        9.67.112.1-9.67.112.64  
    {  
        option 28            9.67.112.127       # broadcast address
```

```

option 9          9.67.112.1      # printer 1
option 9          9.67.112.2      # printer 2
option 15         sandbox.        # domain name
class netbios_host
{
    #Netbi over tcp/ip name server
    option 44 9.67.112.125
    Netbi over tcp/ip node type
    option 46 2
}
}

option 15         toyland         # domain name
option 9          9.68.111.128   # printer 3
option 33         1.2.3.4:9.8.7.1 # route to the moon
option 33         5.6.7.8:9.8.7.2 # route to the mars
# routes to black holes
option 3          11.22.33.44    55.66.77.88
}

```

2. In this example, we see the output of the **dhcpsconf** command. This format is more used by the **dhcpsconf** GUI to store information. This format allows for multiple configurations. The **dhcpsconf** GUI can in turn generate the specific server files for an individual server. The file specifies two of DHCP Servers, Greg and Fred. Each contain the definitions for the two servers. The **dhcpsconf** command can generate files specifically for Greg or Fred. The **dhcpsconf** command will also use the named resources (## sections) to display network pieces that have been named by the administrator. The DHCP server Greg is responsible for network 9.3.145.0, subnet mask 255.255.255.192. The DHCP server Fred is responsible for network 9.3.146.128, subnet mask 255.255.255.240. Each server provides its own domain name. Other options named and unnamed may be placed in the server's configuration section.

Note: This format is used by **dhcpsconf**, which generates the appropriate configuration files for DHCP servers Greg and Fred.

```

# Named resources Section

[dhcpsd command](#)

depend File

Purpose

Describes the format of a software dependencies file.

Description

The **depend** file is an ASCII file used to specify information concerning software dependencies for a particular package. The file is created by a software developer.

Each entry in the **depend** file describes a single software package. The instance of the package is described after the entry line by giving the package architecture and/or version. The format of each entry and subsequent instance definition is:

type pkg name

The fields are:

Entry Definition

type Defines the dependency type. This must be one of the following:

- P** Indicates a prerequisite for installation, for example, the referenced package or versions must be installed.
- I** Implies that the existence of the indicated package or version is incompatible. See also the **X** tag.
- X** Implies that the existence of the indicated package or version is incompatible. This tag should be used instead of the **I** tag.
- R** Indicates a reverse dependency. Instead of defining the packages own dependencies, this designates that another package depends on this one. This type should be used only when an old package does not have a *depend* file but it relies on the newer package nonetheless. Therefore, the present package should not be removed if the designated old package is still on the system since, if it is removed, the old package will no longer work.
- S** Indicates a superseding dependency. It should be used when an earlier package has been superseded by the current package.

pkg Indicates the package abbreviation.

name Specifies the full package name.

Dependency checks may be disabled using the **admin** file.

Examples

Shown below is an example of a *depend* file (for the NFS package):

```
P base Base System
P nsu Networking Support Utilities
P inet Internet Utilities
P rpc Remote Procedure Call Utilities
P dfs Distributed File System Utilities
```

devexports File

Purpose

Lists all devices that can be exported into workload partitions, and lists the devices that are exported by default.

Description

A **devexports** file is a stanza file containing a list of global devices that can be legally exported to workload partitions (WPAR). Devices are specified by **name**, which can contain shell-style wildcards. **devexports** stanzas have the following format:

```
name:  
  value = "{/dev/devname}"  
  auto = "{yes|no}"
```

The stanza header is always **name**. The **value** attribute contains the full path to the device (for example, `/dev/null`) or a shell-style pattern representing multiple devices (for example, `/dev/*random`). The existence of the stanza in the file indicates that one or more devices can be exported. The **auto** attribute indicates whether the device is exported by default. If the **auto** attribute is not specified, `auto=yes` is assumed.

You can configure a workload partition with a **devexports** file using the **-b** flag of the **mkwpar** command or the **restwpar** command. If you do not specify the file, the `/etc/wpars/devexports` file is used by default.

The **-D** flag of the **mkwpar** command can override the default exporting behavior that the **auto** attribute indicates. However, devices that are not represented in the **devexports** file related to the WPAR cannot be exported.

Device exports are synchronized when you run the **startwpar** command, in case configurations have changed since the last run command. Device exports are resynchronized when you run the **chwpar** command to change device-related settings using the **-D** flag.

[restwpar command](#)
[startwpar command](#)
[wparexec command](#)

dir File

Purpose

Describes the format of a directory.

Syntax

```
#include <sys/dir.h>
```

Description

A directory is a file that contains information and structures necessary to define a file hierarchy. A file is interpreted as a directory by the system if it has the **S_IFDIR** file mode. All modifications to the structure of a directory must be performed under the control of the operating system.

The directory file format accommodates component names of up to 256 characters. This is accomplished through the use of a variable-length structure to describe individual directory entries. The structure of a directory entry follows.

Note: This structure is a file system-specific data structure. It is recommended that file system-independent application programs use the file system-independent **direct** structure and its associated library support routines.

```
struct direct {  
    ino_t      d_ino;  
    ushort     d_reclen;  
    ushort     d_namelen;  
    char       d_name[256];  
};
```

By convention, the first two entries in each directory are . (dot) and .. (dot dot). The . (dot) is an entry for the directory itself. The .. (dot dot) entry is for the parent directory. Within the root (/) directory the meaning of .. (dot dot) is modified; because there is no parent directory, the .. (dot dot) entry has the same meaning as the . (dot) entry.

The **DIRSIZ (dp)** macro gives the amount of space required to represent a directory entry. The *dp* argument is a pointer to a **direct** structure.

File systems

/etc/security/domains File

Purpose

Contains the list of valid domains.

Description

The /etc/security/domains file stores the list of valid, user-defined domains available on a system. A domain administrator can modify domains. You can add new domains to this file using the **mkdom** command and modify authorizations using the **chdom** command.

A maximum of 1024 domains are supported.

The /etc/security/domains is an ASCII file that uses a stanza for each domain. Each stanza is identified by the domain name followed by a colon (:). You can list domain attributes individually as Attribute=Value pairs on subsequent lines. Each attribute pair ends with a newline character, as does each stanza. For an example of a stanza, see "Examples" on page 75.

When the system is operating in EnhancedRBAC Mode, changes that you make to the domains file do not impact security considerations until you send the entire domain database to the Kernel Security Tables using the **setkst** command, or until the system is rebooted.

Modifying and listing entries in the domains file

Do not directly edit the /etc/security/domobs file file. Use the following commands and subroutines to manipulate the authorization database:

mkdom

Adds new domains to the **/etc/security/domains** file.

chdom

Changes domain attributes.

lsdom

Displays domain that are defined in this file.

rmdom

Removes entries from this file.

To write programs that affect entries in the **/etc/security/domains** use one or more of the following subroutines:

- **getdomattr**
- **getdomattrs**
- **putdomattr**
- **putdomattrs**

Attributes

A stanza in **/etc/security/domains** file contains one or more of the following attributes :

| Attribute | Definition |
|----------------|--|
| id | Specifies the unique numeric ID of the domain. This is a required attribute and is used internally for security decisions. Do not modify this ID after creating the domain. The value is a unique decimal integer greater than 0. The maximum value of the id can be 1024. |
| dfltmsg | Specifies the default domain-description text if message catalogs are not in use. The value is a character string. |
| msgcat | Specifies the file name of the message catalog that contains the one-line description of the authorization. The value is a character string. |
| msgset | Specifies the message set that contains the authorization description in the message catalog. The value is a decimal integer. |
| msgnum | Specifies the message ID that contains the domain description in the message catalog. The value is a decimal integer. |

Security

The root user and the security group own this file. This files grants read and write access to the root user. Access for other users and groups depends on the security policy for the system.

Examples

The following example for the custom authorization displays a typical stanza in the file:

```
INTRANET:  
id = 1  
dfltmsg = "Custom Authorization"  
msgcat = "custom_auths.cat"  
msgset = 1  
msgnum = 5
```

getdomattr subroutine

mkdom command

chdom command

rmdom command

Role Based Access Control (RBAC)

/etc/security/domobjs File

Purpose

Contains security attributes for domain-assigned objects.

Description

The **/etc/security/domobjs** file is an ASCII stanza file that contains domain-assigned objects and their security attributes. Each stanza in the **/etc/security/domobjs** file is identified by the full path name to the command, followed by a colon (:). Each stanza contains attributes in the Attribute=Value form. The path name must be the absolute path to the objects if the object is of type file or device and cannot contain symbolic links. Each Attribute=Value pair is ended by a newline character, and each stanza is ended by an additional newline character. For an example of a stanza, see "Examples" on page 77.

Note: Domains are not inheritable.

Changes made to the **domobjs** file do not impact security considerations until the entire domain-assigned object database is sent to the Kernel Security Tables through the **setkst** command or until the system is rebooted.

Modifying and Listing Entries in the privcmds File

Do not directly edit the **/etc/security/domobjs** file. Use the following commands and subroutines to manipulate the authorization database:

setsecattr

Adds a command entry to, or changes a command entry in, the **/etc/security/domobjs** file.

lssecattr

Displays attributes and their values.

rmsecattr

Removes a command from the **domobjs** file.

To write programs that affect entries in the **/etc/security/domobjs** file, use one or more of the following subroutines:

- **getobjattr**
- **getobjattrs**
- **putobjattr**
- **putobjattrs**

Attributes

A stanza in this file contains one or more of the following security attributes:

| Attribute | Definition |
|---------------------|--|
| domains | Defines the list of domains that are allowed access to the object. |
| conflictsets | Defines the list of domains that are forbidden from accessing the object. |
| objtype | Defines the type of the object. Valid values are : netint For network interfaces device For block and other devices. The full path to the device should be provided. files For regular files and directories. The full path should be provided to the object name. netport For ports and port ranges. The port number or range of ports should be prefixed with TCP_ or UDP_ |

| Attribute | Definition |
|------------------|---|
| secflags | The security flags for the object. Valid values are FSF_DOM_ALL and FSF_DOM_ANY . It modifies the access behaviour only for the domains attribute. If the value is FSF_DOM_ANY any user/process having any of the domains listed in the attribute domains can access the object. The FSF_DOM_ALL mandates that the user/process accessing the object must have all the domains as listed in the domains attribute. If not provided the default of FSF_DOM_ALL is assumed. |

Security

The root user and the security group own this file. Read and write access is granted to the root user. Access for other users and groups depends on the security policy for the system.

Examples

The following example for an object displays a typical stanza in the file:

```
/usr/local/share/myfile:
domains=INTRANET,APPLICATION
conflictsets=INTERNET
objtype=file
secflags=FSF_DOM_ANY
```

This entry indicates that a user or process desiring access to this object must belong to one of the domains INTRANET or APPLICATION and should not belong to the INTERNET domain

dpid2.conf File

Purpose

Defines the configuration parameters for the **dpid2** daemon.

Description

The **dpid2.conf** file provides the configuration information for the **dpid2** daemon. Stop the daemon using the **stopsrc** command and start it using the **startsrc** command if there are changes to the configuration file. The daemon should be under the System Resource Control (SRC) for issuing these start or stop commands.

Keywords

The directives are specified in the form **<keyword>=<value>**. The following keyword is case-insensitive:

dpiTimeOut

Specifies the timeout in seconds that the **dpid2** daemon waits for the arrival of data from subagents. The default value is 8 seconds. The maximum timeout value is 600 seconds. If you specify any value less than or equal to zero, the default value is taken for processing.

Note: This sample configuration file is in the **/usr/samples/snmpd/dpi2** directory. You must copy the configuration file to the **/etc** directory to use the configurable parameter **dpiTimeOut**.

Examples

The following example sets the configurable parameter *dpiTimeOut* to the maximum value of 600 seconds.

```
dpiTimeOut=600
```

dsinfo File

Purpose

Contains the terminal descriptions for the **Dynamic Screen** utility.

Description

The **dsinfo** file is a database of terminal descriptions used by the **Dynamic Screen** utility. A terminal description typically contains the following configuration information:

- Keys defined for specific use with the **Dynamic Screen** utility and their function
- Number of pages of screen memory available to the terminal
- Code sequences that must be sent or received to access and use Dynamic Screen features

The **dscreen** command reads the appropriate configuration information from the **dsinfo** file to start the **Dynamic Screen** utility.

Entry Format

Line entries in the **dsinfo** file consist of a number of definition fields separated by commas. The first-line field entries are alternate screen names for the terminal. The screen name fields are separated by a | (pipe symbol).

Other line fields are strings describing the capabilities of the terminal definition to the **Dynamic Screen** utility. The following escape codes are recognized within these strings:

| Escape Code | Meaning |
|-------------|---------------------------------------|
| \E,\e | Escape |
| \n,\l | New line |
| \r | Carriage return |
| \t | Tab |
| \b | Backspace |
| \f | Form feed |
| \s | Space |
| \nnn | Character with octal value <i>nnn</i> |
| ^x | Ctrl-x for any appropriate x. |

Any other character preceded by a \ (backslash) yields the character itself.

Strings must be entered as the *type*=*string* parameter, where *type* is the string type and *string* is the string value.

If information is not entered into a string field, a comma is still used to designate the existence of the field.

String Types and String Values

The following string types are available:

String

Type Meaning

dskx Describes the action assigned to a key. This string type contains 4 characters. The 4th character indicates the action to be taken when the keystroke is received by the screen:

Key Type

Action

| | |
|-------------|--|
| dskb | Block input and output. |
| dskc | Start a new screen. |
| dske | End the Dynamic Screen utility (exit code 0). |
| dskl | List keys and actions. |
| dskp | Switch to previous screen. |
| dskq | Quit Dynamic Screen utility (exit code 1). |
| dsks | Select a specific screen. |

Currently, the only valid **dsk** string type endings are b, c, e, l, p, q, and s. Any other key definitions used at this time are interpreted as null values and cause no internal Dynamic Screen action for the terminal definition. Other keys may be assigned values within the **Dynamic Screen** utility at a later time.

Note: The **dskn** string type (n for null or no operation) is guaranteed not to be used for any function assignments in future versions. It is recommended that the **dskn** string type be used instead of other null characters when no internal Dynamic Screen action is desired for a terminal definition.

The value string for each **dskx** string type has three substrings, separated by a | (pipe symbol). (To include a | in one of the substrings, use \\| [backslash, pipe symbol].)

The first substring is the sequence of characters the terminal sends when the key is pressed. The second substring is a label for the key as displayed in the key listing (for example, the Shift-F1 key sequence). The third substring is a sequence of characters the **Dynamic Screen** utility sends to the terminal when the key is pressed, before performing the requested action.

dsp

Describes a physical screen in the terminal. A **dsp** string type must be present for each physical screen in the terminal.

The value string for each physical screen has two substrings, separated by a | (pipe symbol). (To include a | in one of the substrings, use \\| [backslash, pipe symbol].)

The first substring is the sequence of characters to send to the terminal to display and output to the particular named physical page on the terminal. The second substring is usually set to clear the screen sequence. It is sent under the following two conditions:

- The creation of new terminal session
- More terminals are running than there are physical screens.

If your selection of a terminal causes the **Dynamic Screen** utility to reuse one of the physical screens, the clear-the-screen sequence is sent to the screen to indicate that the screen content does not match the output of the terminal connected to it.

Note: Running with more terminals than there are physical screens is not recommended. Avoid this situation by defining no more screen selection keys (**dsks=...**) than physical screens (**dsp=...**).

dst

Adjusts the **Dynamic Screen** utility's input timeout. The value of the string must be a decimal number. The timeout value is in tenths of a second and has a maximum value of 255. The default timeout value is 1, or one tenth of a second.

When the **Dynamic Screen** utility recognizes a prefix of an input sequence but has not yet received all the characters in the sequence, it waits for more characters. If the timeout occurs before more characters are received, the received characters are sent to the screen, and the **Dynamic Screen** utility does not consider these characters as part of an input key sequence. Consider increasing the value of the **dsp** string if one or more of the keys to which the utility has to respond is actually a number of key combinations (for example, <Ctrl-Z> 1, <Ctrl-Z> 2, <Ctrl-Z> 3, and so on, for screen selection, or <Ctrl-Z> N, for new screen).

Examples

1. The following **dsinfo** entry describes a WYSE 60 terminal with three screens:

```
wy60|wyse60|wyse model 60,
  dsks=^A~^M|Shift-F1|,
  dsks=^Aa^M|Shift-F2|,
  dsks=^Ab^M|Shift-F3|,
  dskc=\200|Ctrl-F1|,
  dske=\201|Ctrl-F2|\Ew0\E+,
  dskl=\202|Ctrl-F3|,
  dsp=\Ew0|\E+,
  dsp=\Ew1|\E+,
  dsp=\Ew2|\E+,
```

The <Shift-F1> through <Shift-F3> key combinations are used for selecting screens 1 through 3. <Ctrl-F1> creates a new screen. <Ctrl-F2> sends the key sequence <Esc> w 0 <Esc> + to the screen. As a result, the terminal switches to window 0, the screen is cleared, and the **Dynamic Screen** utility ends. <Ctrl-F3> lists the keys and their functions. The three physical screens are displayed by sending the key sequences <Esc> w 0, <Esc> w 1, and <Esc> w 2, respectively. Each time a physical screen is used for a new screen the <Esc> + key sequence is sent to the terminal to clear the screen.

2. The following **dsinfo** entry describes a WYSE 60 terminal with three screens, one of which is on a second computer communicating through the second serial port on the terminal. The **Dynamic Screen** utility must be run on both computers, with terminal type WY60-1 on the first computer and terminal type WY60-2 on the second computer (to do so specify the **-t** flag in the **dscreen** command).

```
wy60-1|wyse60-1|wyse model 60 - first
serial port
  dsks=^A~^M|Shift-F1|,
  dsks=^Aa^M|Shift-F2|,
  dskb=^Ab^M|Shift-F3|\Ed#^Ab\r^T\Ee9,
  dskc=\200|Ctrl-F1|,
  dske=\201|Ctrl-F2|\Ed#\201^T\Ew0\E+,
  dskl=\202|Ctrl-F3|,
  dsp=\Ew0|\E+,dsp=\Ew1|\E+,
wy60-2|wyse60-2|wyse model 60 - second
serial port
  dskb=^A~^M|Shift-F1|\Ed#^A`\r^T\Ee8,
  dskb=^Aa^M|Shift-F2|\Ed#^Aa\r^T\Ee8,
  dsks=^Ab^M|Shift-F3|
  dskc=\200|Ctrl-F1|,
  dske=\201|Ctrl-F2|\Ed#\201^T\Ew0\E+,
  dskl=\202|Ctrl-F3|,
  dsp=\Ew2|\E+,
```

The first two key entries for terminal type WY60-1 are identical to the entry in example 1. The third key entry, of type dskb, specifies that input and output are blocked when the <Esc> d # <Ctrl-A> b <CR> <Ctrl-T> <Esc> e 9 key sequence is sent to the terminal. As a result, output is blocked, and the **Dynamic Screen** utility continues to scan input for key sequences but discards

all other input. The <Esc> d # sequence puts the terminal in transparent print mode, which echoes all keystrokes up to <Ctrl-T> out the other serial port. The <Ctrl-A> b <CR> key sequence is sent out to the other serial port, informing the **Dynamic Screen** utility on the second computer that it should activate the window associated with the <Shift-F3> key. The <Ctrl-T> key sequence takes the terminal out of transparent print mode, and the <Esc> e 9 key sequence informs the terminal to switch to the other serial port for data communications.

The other computer takes over and sends the <Esc> w 2 key sequence to switch to the third physical screen and then resumes normal communication.

The WY60-2 entry follows the same general pattern for the <Shift-F1> and <Shift-F2> key combinations, which switch to transparent print mode, send a function key string to the other computer, switch transparent print off, and switch to the other serial port.

The end key <Ctrl-F2> works the same for both computers. It sends the end key sequence to the other computer through the transparent print mechanism, switches the terminal to window 0, clears the screen, and exits.

dumpdates File

Purpose

Describes the format of the **dumpdates** file.

Description

The **/etc/dumpdates** file holds filesystem backup information for the **backup** and **rdump** commands. The **dumpdates** file is maintained by using the **-u** option when performing file system backups. The following is the **dumpdates** data structure:

```
struct idates {
    char id_name[MAXNAMLEN+3];
    char id_incno;
    time_t id_ddate;
}
```

The **struct idates** describes an entry in the **/etc/dumpdates** file where the backup history is kept. The fields of the structure are:

| Item | Description |
|-----------|--|
| id_name | The name of the file system. |
| id_incno | The level number of the last backup. |
| id_ddate | The date of the incremental backup in system format. |
| MAXNAMLEN | The maximum value of this variable is 255. |

e789_ctbl File for HCON

Purpose

Contains the default binary color definition table for HCON.

Description

The `/usr/lib/hcon/e789_ctbl` file contains the default color definition table for the Host Connection Program (HCON) in binary form.

Instances of the `e789_ctbl` file can also occur in user `$HOME` directories. The color definition table can be customized using the `hconutil` command. If the user issuing the `hconutil` command does not specify a name for the new table, the command names the `e789_ctbl` table and places it in the user `$HOME` directory. To use a customized table, an HCON user must specify the file name of the table in an HCON session profile.

`chhcons` command

e789_ktbl File for HCON

Purpose

Contains the default binary keyboard definition table used by HCON.

Description

The `/usr/lib/hcon/e789_ktbl` file contains the default keyboard definition table used by the Host Connection Program (HCON) in binary form.

HCON key names are mapped to specific keys on each supported keyboard. The HCON emulator program uses these key mappings to generate the correct key function on all the supported keyboards. HCON key mappings can be customized using the `hconutil` command.

Instances of the `e789_ktbl` file can also occur in user `$HOME` directories. The keyboard definition table can be customized using the `hconutil` command. If the user issuing the `hconutil` command does not specify a name for the new table, the command names the `e789_ktbl` table and places it in the user `$HOME` directory. To use a customized table, an HCON user must specify the file name of the table in an HCON session profile.

`chhcons` command

eimadmin.conf File

Purpose

Stores system Enterprise Identity Mapping (EIM) connection information from the `eimadmin` command.

Description

This file is used to store system Enterprise Identity Mapping (EIM) connection information from the **eimadmin** command. Use the **eimadmin** command to create and update this file. The connection information stored by the **eimadmin.conf** file includes the EIM domain and its controlling server, the identity with which to authenticate (bind) to the server, and the authentication method.

The meanings of the **eimadmin.conf** file's fields are as follows:

| Item | Description |
|--------------------------------|---|
| LdapURL | Specifies the URL and port for the LDAP server controlling the EIM data. This field takes the following format: <code>ldap://some.ldap.host:389</code> <code>ldaps://secure.ldap.host:636</code> |
| KerberosRegistry | Specifies the name of a Kerberos registry. |
| LocalRegistry EimDomain | Specifies the full distinguished name (DN) of the EIM domain. This name begins with <code>ibm-eimDomainName=</code> and consists of the following elements: <i>domainName</i> The name of the EIM domain you are creating. For example, <code>MyDomain</code> . <i>parent distinguished name</i> The distinguished name for the entry immediately above the given entry in the directory information tree hierarchy, such as <code>o=ibm,c=us</code> . For example: <code>ibm-eimDomainName=MyDomain,o=ibm,c=us</code> |
| ConnectionMethod | Specifies the method of authentication to the LDAP server. You can select one of the following methods: <ul style="list-style-type: none">• SIMPLE (bind DN and password). (DEFAULT method).• CRAM-MD5 (bind DN and protected password).• EXTERNAL (digital certificate).• GSSAPI (Kerberos). Uses the default Kerberos credential. The credential must be established using a service such as kinit before running EIM. |
| BindDn | The distinguished name to use for the simple bind to LDAP. For example, <code>cn=admin</code> . The bind distinguished name has one of the following EIM authorities: <ul style="list-style-type: none">• EIM administrator• EIM registries administrator• EIM registry X administrator• EIM identifiers administrator |
| BindPassword | Specifies the password associated with the bind DN. |
| SSLKeyFile | The name of the SSL key database file, including the full path name. If the file cannot be found, the name of a RACF® key ring that contains authentication certificates is used. This value is required for SSL communications with a secure LDAP host. For example: <code>/u/eimuser/ldap.kdb</code> |
| SSLKeyPassword | The password required to access the encrypted information in the key database file. As an alternative, you can specify an SSL password stash file by prefixing the stash file name with <code>file://</code> . For example: <code>file:///u/eimuser/ldapclient.sth</code> |
| SSLKeyCert | Identifies which certificate to use from the key database file or RACF key ring. If a certificate label is not specified, the default certificate in the file or ring is used. |

Example

```
-> /usr/bin/eimadmin -X -d ibm-eimDomainName='ibm-eimDomainName=MyDomain,o=ibm,c=us'  
      -h 'ldap://keystone.austin.ibm.com:389' -S 'SIMPLE'-b 'cn=admin' -w 'secret'  
-> cat /etc/eimadmin.conf  
EimConfiguration:  
  LdapURL="ldap://keystone.austin.ibm.com:389"  
  KerberosRegistry=""  
  LocalRegistry=""  
  EimDomain="ibm-eimDomainName=MyDomain,o=ibm,c=us"  
  ConnectionMethod="SIMPLE-b"
```

```

BindDn=""
BindPassword=""
SSLKeyFile=""
SSLKeyPassword=""
SSLKeyCert=""

->

```

Location

| Item | Description |
|--------------------|---|
| /etc/eimadmin.conf | Contains the eimadmin.conf file. |

Related information:
eimadmin command

environ File

Purpose

Defines the environment attributes for users.

Description

The **/etc/security/environ** file is an ASCII file that contains stanzas with the environment attributes for users. Each stanza is identified by a user name and contains attributes in the *Attribute=Value* form, with a comma separating the attributes. Each attribute is ended by a new-line character, and each stanza is ended by an additional new-line character.

If environment attributes are not defined, the system uses default values. Each user stanza can have the following attributes:

| Attribute | Definition |
|---------------|--|
| usrenv | Defines variables to be placed in the user environment when the initial login command is given or when the su command resets the environment. The value is a list of comma-separated attributes. The default value is an empty string. |
| sysenv | Defines variables to be placed in the user protected state environment when the initial login command is given or when the su command resets the environment. These variables are protected from access by unprivileged programs so other programs can depend on their values. The default value is an empty string. |

For a description of environment variables, refer to the **/etc/environment** file.

Access to all the user database files should be through the system commands and subroutines defined for this purpose. Access through other commands or subroutines may not be supported in future releases.

The **mkuser** command creates a user stanza in this file. The initialization of the attributes depends upon their values in the **/usr/lib/security/mkuser.default** file. The **chuser** command can change these attributes, and the **lsuser** command can display them. The **rmuser** command removes the entire record for a user.

Security

Access Control:

This command should grant read (r) access to the root user, members of the security group, and others consistent with the security policy for the system. Only the root user should have write (w) access.

Auditing Events:

| Event | Information |
|-----------------|-------------|
| S_ENVIRON_WRITE | file name |

Examples

A typical stanza looks like the following example for user dhs:

```
dhs:
  usrenv = "MAIL=/home/spool/mail/dhs,MAILCHECK=600"
  sysenv = "NAME=dhs@delos"
```

Files

| Item | Description |

chuser command

login command

rmuser command

File and system security

environment File

Purpose

Sets up the user environment.

Description

The **/etc/environment** file contains variables specifying the basic environment for all processes. When a new process begins, the **exec** subroutine makes an array of strings available that have the form *Name=Value*. This array of strings is called the environment. Each name defined by one of the strings is called an *environment variable* or *shell variable*. The **exec** subroutine allows the entire environment to be set at one time.

Environment variables are examined when a command starts running. The environment of a process is not changed by altering the **/etc/environment** file. Any processes that were started prior to the change to the **/etc/environment** file must be restarted if the change is to take effect for those processes. If the **TZ** variable is changed, the **cron** daemon must be restarted, because this variable is used to determine the current local time.

The following restrictions apply, when modifying the **environment** file:

- Ensure that newly created environment variables do not conflict with standard variables such as **MAIL**, **PS1**, **PS2**, and **IFS**.

- Ensure that the information in the **environment** file is in the *Name=Value* format. Unlike **profile** scripts, the **environment** file is not a shell script and does not accept data in any format other than the *Name=Value* format.

The Basic Environment

When you log in, the system sets environment variables from the **environment** file before reading your login profile, **.profile**.

The following variables make up the basic environment:

| Variable | Description |
|-------------------|---|
| HOME | The full path name of the user login or HOME directory. The login program sets this to the name specified in the /etc/passwd file. |
| LANG | The locale name currently in effect. The LANG variable is set in the /etc/environment file at installation time. |
| NLSPATH | The full path name for message catalogs. The default is: /usr/lib/nls/msg/%L/%N: /usr/lib/nls/msg/%L/%N.cat: |
| | where %L is the value of the LC_MESSAGES category and %N is the catalog file name. Note: See the chlang command for more information about changing message catalogs. |
| LC_FASTMSG | If LC_FASTMEG is set to false , POSIX-compliant message handling is performed. If LC_FASTMSG is set to true , it specifies that default messages should be used for the C and POSIX locales and that NLSPATH is ignored. If this variable is set to anything other than false or unset , it is considered the same as being set to true . The default value is LC_FASTMSG=true in the /etc/environment file. |
| LOCPATH | The full path name of the location of National Language Support tables. The default is /usr/lib/nls/loc and is set in the /etc/profile file. If the LOCPATH variable is a null value, it assumes that the current directory contains the locale files. Note: All setuid and setgid programs will ignore the LOCPATH environment variable. |
| PATH | The sequence of directories that commands such as the sh , time , nice and nohup commands search when looking for a command whose path name is incomplete. The directory names are separated by colons. |
| TZ | The time-zone information. The TZ environment variable is set by the /etc/environment file. The TZ environment variable has the following format (spaces inserted for readability): std offset dst offset , rule |
| | The fields within the TZ environment variable are defined as follows: |
| | std and dst Designate the standard (std) and summer (dst) time zones. Only the std value along with the appropriate offset value is required. If the dst value is not specified, summer time does not apply. The values specified may be no less than three and no more than TZNAME_MAX bytes in length. The length of the variables corresponds to the %Z field of the date command; for libc and libbsd , TZNAME_MAX equals three characters. Any nonnumeric ASCII characters except the following may be entered into each field: a leading : (colon), a , (comma), a - (minus sign), a + (plus sign), or the ASCII null character. Note: POSIX 1.0 reserves the leading : (colon) for an implementation-defined TZ specification. The operating system disallows the leading colon, selecting CUT0 and setting the %Z field to a null string. |
| | An example of std and dst format is as follows: EST5EDT |
| | Note: If the value set is invalid or unrecognized, the time zone defaults to UTC/GMT. |
| EST | Specifies Eastern U.S. standard time. |

| Variable | Description |
|-----------------|---|
| 5 | Specifies the offset, which is 5 hours behind Coordinated Universal Time (CUT). |
| | <p>EDT Specifies the corresponding summer time zone abbreviation.</p> <p>Note: See "Time Zones" for a list of time zone names defined for the system.</p> |
| | <p>offset Denotes the value added to local time to equal Coordinated Universal Time (CUT). CUT is the international time standard that has largely replaced Greenwich Mean Time. The offset variable has the following format:</p> <p>hh:mm:ss</p> <p>The fields within the offset variable are defined as follows:</p> |
| hh | Specifies the dst offset in hours. This field is required. The hh value can range between the integers -12 and +11. A negative value indicates the time zone is east of the prime meridian; a positive value or no value indicates the time zone is west of the prime meridian. |
| mm | Specifies the dst offset detailed to the minute. This field is optional. If the mm value is present, it must be specified between 0 and 59 and preceded by a : (colon). |
| ss | Specifies the dst offset detailed to the second. The ss field is optional. If the ss value is present, it must be specified between 0 and 59 and preceded by a : (colon). |
| | An offset variable must be specified with the std variable. An offset variable for the dst variable is optional. If no offset is specified with the dst variable, the system assumes that summer time is one hour ahead of standard time. |
| | As an example of offset syntax, Zurich is one hour ahead of CUT, so its offset is -1. Newfoundland is 1.5 hours ahead of eastern U.S. standard time zones. Its syntax can be stated as any of the following: 3:30, 03:30, +3:30, or 3:30:00. |
| | <p>rule The rule variable indicates when to change to and back from summer time. The rule variable has the following format:</p> <p>start/time,end/time</p> <p>The fields within the rule variable are defined as follows:</p> |
| start | Specifies the change from standard to summer time. |
| end | Specifies the return to standard time from summer time. |
| time | Specifies when the time changes occur within the time zone. For example, if the time variable is encoded for 2 a.m. then the time changes when the time zone reaches 2 a.m. on the date specified in the start variable. |

| Variable | Description |
|----------|--|
| / | Delimits the start date, end date, and time variables. |
| , | (Comma) Delimits two date and time pairs. |
| J | The start and end variables support a syntax for Julian time (J) and a syntax for leap years (M): |
| Jn | |
| Mm.n.d | |
| | In the J syntax, the n variable has the value of 1 through 365. Leap days are not counted. In the M syntax, m is the month, n the week, and d the day of the week starting from day 0 (Sunday). |
| | The rule variable has the same format as the offset variable except no leading - (minus sign) or + (plus sign) is allowed. The default of the start variable is 02:00:00 (2 a.m.). |
| | Note: The time zone offsets and time change points are interrelated and context-dependent. The rule variable's runtime execution semantics change as a function of the offsets. For example, if the summer time zone changes one hour, as in CST6CDT5, (the default 2 a.m.) summer time changes instantaneously from 2 a.m. to 3 a.m. CDT. The fall change is from 2 a.m. CDT to 1 a.m. CST. The respective changes for a time zone of CST6CDT4 are 2 a.m. CST to 4 a.m. CDT and 2 a.m. CDT to 12 a.m. CST. |
| | In an example of the rule variable, if the law changed so that the Central United States experienced summer time between Julian 129 and Julian 131, the TZ variable would be stated as follows: |
| | TZ=CST6CDT5,J129,J131 |
| | In this example, the dates indicated are May 09 and May 11, 1993, respectively. (Use the date +%j command to get the Julian date number.) |
| | In another example, if the time changes were to occur at 2 a.m. CST and 19:30 CDT, respectively, the variables would be stated as follows: |
| | TZ=CST6CDT5,J129,J131/19:30 |
| | In nonleap years, the fallback time change would be from 19:30 CDT to 18:30 CST on May 11 (1993). |
| | For the leap year (M) syntax, the spring ahead date would be 2 May and the fallback date is 9 May. The variables are stated as follows: |
| | TZ=CST6CDT5,M5.1.0,M5.2.0 |

Time Zones

The system defines the following time zones and time zone names:

Note: Coordinated Universal Time (CUT) is the international time standard.

Table 1. Time Zones Defined on the System

| Name | Time Zone | CUT Offset |
|-------------------|---------------------------------|------------|
| CUT0GDT | Coordinated Universal Time | CUT |
| GMT0BST | United Kingdom | CUT |
| WET0WEST | Western Europe | CUT |
| AZOREST1AZOREDT | Azores, Cape Verde | CUT -1 |
| FALKST2FALKDT | Falkland Islands | CUT -2 |
| GRNLNDST3GRNLNDDT | Greenland, East Brazil | CUT -3 |
| AST4ADT | Central Brazil | CUT -4 |
| EST5EDT | Eastern United States, Colombia | CUT -4 |
| CST6CDT | Central United States, Honduras | CUT -6 |
| MST7MDT | Mountain United States | CUT -7 |

Table 1. Time Zones Defined on the System (continued)

| Name | Time Zone | CUT Offset |
|-------------|------------------------------|------------|
| PST8PDT | Pacific United States, Yukon | CUT -8 |
| AST9ADT | Alaska | CUT -9 |
| HST10HDT | Hawaii, Aleutian Islands | CUT -10 |
| BST11BDT | Bering Strait | CUT -11 |
| NZST-12NZDT | New Zealand | CUT +12 |

| Item | Description | |
|----------------|---------------------------|---------|
| MET-11METDT | Solomon Islands | CUT +11 |
| EET-10EETDT | Eastern Australia | CUT +10 |
| JST-9JSTDT | Japan | CUT +9 |
| KORST-9KORDT | Korea | CUT +9 |
| WAUST-8WAUDT | Western Australia | CUT +8 |
| TAIST-8TAIDT | Taiwan | CUT +8 |
| THAIST-7THAIDT | Thailand | CUT +7 |
| TASHST-6TASHDT | Central Asia | CUT +6 |
| PAKST-5PAKDT | Pakistan | CUT +5 |
| WST-4WDT | Gorki, Central Asia, Oman | CUT +4 |
| MEST-3MEDT | Turkey | CUT +3 |
| SAUST-3SAUDT | Saudi Arabia | CUT +3 |
| EET-2EEST | Eastern Europe | CUT +2 |
| USAST-2USADT | South Africa | CUT +2 |
| CET-1CEST | Central Europe | CUT +1 |

Files

| Item | Description |
|------------------|--|
| /etc/profile | Specifies variables to be added to the environment by the shell. |
| /etc/environment | Specifies the basic environment for all processes. |
| \$HOME/.profile | Specifies the environment for specific user needs. |
| /etc/passwd | Specifies user IDs. |

errors File for BNU

Purpose

Contains a record of **uucico** daemon errors.

Description

The **/var/spool/uucp/.Admin/errors** file contains a record of **uucico** daemon errors that the Basic Networking Utilities (BNU) program cannot correct. For example, if the **uucico** daemon is unable to access a directory that is needed for a file transfer, the BNU program records this in the **errors** file.

If debugging is enabled for the **uucico** daemon, the BNU program sends the error messages to standard output instead of to the **errors** file.

Examples

The text of an error which might appear in the **errors** file is:

```
ASSERT ERROR (uucico) pid: 303 (7/18-8:25:09) SYSTAT OPEN FAIL /v  
ar/spool/uucp/.Status/ (21) [SCCSID: @(#)systat.c 7.2 87/07/08  
16:43:37, FILE: systat.c, LINE:100]
```

This error occurred on July 18 at 8:25:09 a.m. [(7/18-8:25:09)] when the **uucico** daemon, running as process 303 [(uucico) pid: 303], could not open the **/var/spool/uucp/.Status** directory [SYSTAT OPEN FAIL /var/spool/uucp/.Status/]. To prevent this error from occurring again, you should make sure the permissions for the **.Status** directory are correct. It should be owned by the **uucp** login ID and group **uucp**, with permissions of 777 (read, write, and execute for owner, group, and all others).

Files

| Item | Description |
|---|--|
| /var/spool/uucp/.Admin directory | Contains the errors file and other BNU administrative files. |
| /var/spool/uucp/.Status/SystemName | Lists the last time a remote system was contacted and the minimum time until the next retry. |
| /var/spool/uucp/.Admin/errors | Specifies the path of the errors file. |

ethers File for NIS

Purpose

Contains the Ethernet addresses of hosts on the Internet network.

Description

The **/etc/ethers** file contains information regarding the known (48-bit) Ethernet addresses of hosts on the Internet. The file contains an entry for each host. Each entry consists of the following information:

- Ethernet address
- Official host name

Items are separated by any number of blanks or tab characters. A # (pound sign) indicates the beginning of a comment that extends to the end of the line.

The standard form for Ethernet addresses is x:x:x:x:x:x: where x is a hexadecimal number between 0 and ff, representing one byte. The address bytes are always in network order. Host names may contain

any printable character other than a space, tab, new line, or comment character. It is intended that host names in the **/etc/ethers** file correspond to the host names in the **/etc/hosts** file.

This file is part of NFS in Network Support Facilities.

Files

| Item | Description |
|--------------------|---|
| /etc/ethers | Specifies the path of the ethers file. |
| /etc/hosts | Contains Internet addresses. |

NFS Services

Network Information Service Overview

events File

Purpose

Contains information about system audit events.

Description

The **/etc/security/audit/events** file is an ASCII stanza file that contains information about audit events. The file contains just one stanza, **auditpr**, which lists all the audit events in the system. The stanza also contains formatting information that the **auditpr** command needs to write an audit tail for each event.

Each attribute in the stanza is the name of an audit event, with the following format:

AuditEvent = FormatCommand

The root users can edit the events file using the **vi** editor. The comments in an events file begin with an asterisk sign (*).

The format command can have the following parameters:

| Parameter | Description |
|-----------------------------|--|
| (empty) | The event has no tail. |
| printf <i>Format</i> | The tail is formatted according to the string supplied for the <i>Format</i> parameter. The %x symbols within the string indicate places for the audit trail to supply data. |
| <i>Program -i n Arg ...</i> | The tail is formatted by the program specified by the <i>Program</i> parameter. The <i>-i n</i> parameter is passed to the program as its first parameter, indicating that the output is to be indented by <i>n</i> spaces. Other formatting information can be specified with the <i>Arg</i> parameter. The audit event name is passed as the last parameter. The tail is written to the standard input of the program. |

Audit Event Formatting Information

| Format | Description |
|--------|---|
| %A | Formatted output is similar to the acget command. |
| %c | Format a single byte as a character. |
| %D | Formatted as a device major and minor number. |
| %d | Formatted as a 32-bit signed decimal integer |
| %G | Formatted as a comma-separated list of group names or numerical identifiers. |
| %L | Formatted as a text string which describes the identity associated with an Internet socket and the socket itself. |
| %ld | Formatted as a 64-bit signed decimal integer |
| %lo | Formatted as a 64-bit octal value. |
| %lx | %lx Formatted as a 64-bit hexadecimal value. |
| %lX | Formatted as a 64-bit hexadecimal value with uppercase letters. |
| %o | Formatted as 32-bit octal integer. |
| %P | Formatted output is similar to the pclget command. |
| %S | Formatted as a text string which describes an Internet socket. |
| %s | Formatted as a text string. |
| %T | Formatted as a text string giving include date and time with 6 significant digits for the seconds DD Mmm YYYY HH:MM:SS:mmmuuu). |
| %u | Formatted as a 32-bit unsigned integer. |
| %x | Formatted as a 32-bit hexadecimal integer. |
| %X | Formatted as a 32-bit hexadecimal integer with upper case letters. |
| %% | A single '%' character. |

Security

Access Control: This file should grant read (r) access to the root user and members of the audit group, and grant write (w) access only to the root user.

Examples

To format the tail of an audit record for new audit events, such as FILE_Open and PROC_Create, add format specifications like the following to the **auditpr** stanza in the **/etc/security/audit/events** file:

```
auditpr:
  FILE_Open = printf "flags: %d mode: %o \
    fd: %d filename: %s"
  PROC_Create = printf "forked child process %d"
```

Files

| Item | Description |
|---------------------------------------|--|
| /etc/security/audit/events | Specifies the path to the file. |
| /etc/security/audit/config | Contains audit system configuration information. |
| /etc/security/audit/objects | Contains information about audited objects. |
| /etc/security/audit/bincmds | Contains auditbin backend commands. |
| /etc/security/audit/streamcmds | Contains auditstream commands. |

Setting Up Auditing

Security Administration

Execute (X.*) Files for BNU

Purpose

Contains instructions for running commands that require the resources of a remote system.

Description

The execute (X.*) files of the Basic Networking Utilities (BNU) contain instructions for running commands that require the resources of a remote system. They are created by the **uux** command.

The full path name of a **uux** command execute file is a form of the following:

/var/spool/uucp/SystemName/X.RemoteSystemNxxxx

where the *SystemName* directory is named for the local computer and the *RemoteSystem* directory is named for the remote system. The *N* character represents the grade of the work, and the *xxxx* notation is the four-digit hexadecimal transfer-sequence number; for example, X.zeusN2121.

Note: The grade of the work specifies when the file is to be transmitted during a particular connection. The grade notation is a single number (0-9) or letter (A-Z, a-z). Lower sequence characters cause the file to be transmitted earlier in the connection than do higher sequence characters. The number 0 is the highest grade, signifying the earliest transmittal; z is the lowest grade, specifying the latest transmittal. The default grade is N.

Standard Entries in an Execute File

An execute file consists of several lines, each with an identification character and one or more entries:

User Line

| Identification Character | Description |
|------------------------------|---|
| U <i>UserName SystemName</i> | Specifies the login name of the user issuing the uux command and the name of the system that issued the command. |

Error Status Line

| Identification Character | Description |
|--------------------------|---|
| N or Z | Indicates the error status. |
| N | Indicates that a failure message is <i>not</i> sent to the user issuing the uux command if the specified command does not execute successfully on the remote system. |
| Z | Indicates that a failure message is sent to the user issuing the uux command if the specified command does not execute successfully on the remote system. |

Requester Name

| Identification Character | Description |
|--------------------------|---|
| R <i>UserName</i> | Specifies the login ID of the user requesting the remote command execution. |

Required File Line

| Identification Character | Description |
|--------------------------|--|
| F <i>FileName</i> | <p>Contains the names of the files required to execute the specified command on the remote system. The <i>FileName</i> parameter can be either the complete path name of the file, including the unique transmission name assigned by the BNU program, or simply the transmission name without any path information.</p> <p>The required file line can contain zero or more file names. The uuxqt daemon checks for the existence of all listed files before running the specified command.</p> |

Standard Input Line

| Identification Character | Description |
|--------------------------|--|
| I <i>FileName</i> | <p>Specifies the standard input to be used.</p> <p>The standard input is either specified by a < (less than) symbol in the command string or inherited from the standard input of the uux command if that command was issued with the - (minus sign) flag.</p> <p>If standard input is specified, the input source is also listed in an F (Required File) line. If standard input is not specified, the BNU program uses the /dev/null device file.</p> |

Standard Output Line

| Identification Character | Description |
|------------------------------|--|
| O <i>FileName SystemName</i> | <p>Specifies the names of the file and system that are to receive standard output from the command execution. Standard output is specified by a > (greater than) symbol within the command string. (The >> sequence is not valid in uux commands.) As is the case with standard input, if standard output is not specified, the BNU program uses the /dev/null device file.</p> |

Command Line

| Identification Character | Description |
|--------------------------|---|
| C <i>CommandString</i> | <p>Gives the command string that the user requests to be run on the specified system. The BNU program checks the /etc/uucp/Permissions file on the designated computer to see whether the login ID can run the command on that system.</p> <p>All required files go to the execute file directory, usually /var/spool/uucp/.Xqtdir. After execution, the standard output is sent to the requested location.</p> |

Examples

1. User amy on local system zeus issued the following command:

```
uux - "diff /home/amy/out hera!/home/amy/out2 > ~/DF"
```

The command in this example invokes the **uux** command to run a **diff** command on the local system, comparing the **/home/amy/out** file with the **/home/amy/out2** file, which is stored on remote system **hera**. The output of the comparison is placed in the **DF** file in the public directory on the local system.

The preceding command produces the **/var/spool/uucp/hera/X.zeusN212F** execute file, which contains the following information:

The user line identifies the user **amy** on the system **zeus**. The error-status line indicates that **amy** will receive a failure status message if the **diff** command fails to execute. The requestor is **amy**, and the file required to execute the command is the following data file:

```

U amy zeus
# return status on failure
Z
# return address for status or input return
R amy
F /var/spool/uucp/hera/D.hera1e954fd out2
O ~/DF zeus
C diff /home/amy/out out2
/var/spool/uucp/hera/D.hera1e954fd out2

```

The output of the command is to be written to the public directory on the system zeus with the file name DF. (The ~ (tilde) is the shorthand way of specifying the public directory.) The final line is the command string that the user amy entered with the **uux** command.

2. The following is another example of an execute file:

```

U uucp hera
# don't return status on failure
N
# return address for status or input return
R uucp
F D.hera5eb7f7b
I D.hera5eb7f7b
C rmail amy

```

This indicates that user uucp on system hera is sending mail to user amy, who is also working on system hera.

Files

| Item | Description |
|--|--|
| /etc/uucp/Permissions | Describes access permissions for remote systems. |
| /etc/uucp/Systems | Describes accessible remote systems. |
| /var/spool/uucp/ <i>SystemName</i> directory | Contains BNU command, data, and execute files. |
| /var/spool/uucp/ <i>SystemName</i> /C.* | Contains instructions for transfers. |
| /var/spool/uucp/Xqtdir directory | Contains lists of commands that remote systems are permitted to execute. |
| /var/spool/uucppublic/* directory | Contains transferred files. |

[BNU File and Directory Structure](#)

exports File for NFS

Purpose

Contains a list of directories that can be exported to Network File System (NFS) clients.

Description

The **/etc/exports** file contains an entry for each directory that can be exported to NFS clients. This file is read automatically by the **exportfs** command. If you change this file, you must run the **exportfs** command before the changes can affect the way the daemon operates.

Only when this file is present during system startup does the **rc.nfs** script execute the **exportfs** command and start the **nfsd** and **mountd** daemons.

Restriction: You cannot export either a parent directory or a subdirectory of an exported directory within the same file system.

If there are two entries for the same directory with different NFS versions 2 (or 3) and NFS versions 4 in the **/etc(exports** file, the **exportfs** command exports both of the two entries.

If the options for NFS versions 2 (or 3) and 4 are the same for a directory, there can be one entry in the **/etc(exports** file specifying **-vers=3:4**.

Entries in the file are formatted as follows:

Directory-Option [, Option] ...

These entries are defined as follows:

| Entry | Definition |
|------------------|--|
| <i>Directory</i> | Specifies the directory name. |
| <i>Option</i> | Specifies the optional characteristics for the directory being exported. You can enter more than one variable by separating them with commas. For options taking a Client parameter, Client can specify a hostname, a dotted IP address, a network name, or a subnet designator. A subnet designator is of the form <i>@host/mask</i> , where host is either a hostname or a dotted IP address and mask specifies the number of bits to use when checking access. If <i>mask</i> is not specified, a full mask is used. For example, the designator <i>@client.group.company.com/16</i> will match all Clients on the company.com subnet. A designator of <i>@client.group.company.com/24</i> will match only the Clients on the group.company.com subnet. Choose from the following options: <i>ro</i> Exports the directory with read-only permission. If not specified, the directory is exported with read-write permission. <i>ro=Client[:Client]</i> Exports the directory with read-only permission to the specified Clients. Exports the directory with read-write permissions to Clients not specified in the list. A read-only list cannot be specified if a read-write list has been specified. <i>rw</i> Exports the directory with read-write permission to all Clients. <i>rw = Client [:Client]</i> Exports the directory with read-write permission to the specified Clients. Exports the directory read-only to Clients not in the list. A read-write list cannot be specified if a read-only list has been specified. <i>access = Client[:Client,...]</i> Gives mount access to each Client listed. If not specified, any Client is allowed to mount the specified directory. The ro option and the rw option can be combined on a single exports entry. See the following examples: access=x, ro=y indicates that x has the rw option and y has the ro option access=x, rw=y indicates that x has the ro option and y has the rw option <i>anon= UID</i> If a request comes from a root user, use the user identification (<i>UID</i>) value as the effective user ID. The default value for this option is -2. Setting the value of the <i>anon</i> option to -1 disables anonymous access. Note that, by default, secure NFS accepts nonsecure requests as anonymous, and users who want more security can disable this feature by setting <i>anon</i> to a value of -1. |

| Entry | Definition |
|-------------------------------|--|
| root=Client[:Client] | Allows root access from the specified clients in the list. Putting a host in the root list does not override the semantics of the other options. For example, this option denies the mount access from a host present in the root list but absent in the access list. |
| secure | Requires clients to use a more secure protocol when accessing the directory. |
| | A # (pound sign) anywhere in the file indicates a comment that extends to the end of the line. |
| deleg={yes no} | Enable or disable file delegation for the specified export. This option overrides the system-wide delegation enablement for this export. The system-wide enablement is done through the nfs0 command. |
| vers=version[:version] | Exports the directory for clients using the specified nfs protocol versions. Allowable values are 2, 3, and 4. Versions 2 and 3 cannot be enforced separately. Specifying version 2 or 3 allows access by clients using either nfs protocol versions 2 or 3. Version 4 can be specified independently and must be specified to allow access by clients using version 4 protocol. The default is 2 and 3. |
| exname=external-name | Exports the directory by the specified external name. The external name must begin with the nfsroot name. See below for a description of the nfsroot and nfspublic paths. This applies only to directories exported for access by version 4 protocol only. |

Entry*Option* (continued)**Definition****sec=flavor[;flavor...]**

This option is used to specify a list of security methods that may be used to access files under the exported directory. Most **exportfs** options can be clustered using the **sec** option. Options following a **sec** option are presumed to belong with the preceding **sec** option. Any number of **sec** stanzas may be specified, but each security method can be specified only once. Within each **sec** stanza the **ro**, **rw**, **root**, and **access** options may be specified once. Only the **public**, **anon** and **vers** options are considered global for the export. If the **sec** option is used to specify any security method, it must be used to specify all security methods. In the absence of any **sec** option, UNIX authentication is assumed.

Allowable flavor values are:

- sys** UNIX authentication.
- dh** DES authentication.
- krb5** Kerberos. Authentication only.
- krb5i** Kerberos. Authentication and integrity.
- krb5p** Kerberos. Authentication, integrity, and privacy.
- none** Allow mount requests to proceed with anonymous credentials if the mount request uses an authentication flavor not specified in the export. Otherwise a weak **auth** error is returned. By default, all flavors are allowed.

The **secure** option may be specified, but not in conjunction with a **sec** option. The **secure** option is deprecated and may be eliminated. Use **sec=dh** instead.

refer=rootpath@host [+host][::rootpath@host [+host]]

A namespace referral is created at the specified path. This referral directs clients to the specified alternate locations where the clients can continue operations. A referral is a special object. If a non-referral object exists at the specified path, the export is not allowed and an error message is printed. If nothing exists at the specified path, a referral object is created there; this referral object includes the pathname directories that lead to the object. Multiple referrals can be created within a file system. A referral cannot be specified for **nfsroot**. The name **localhost** cannot be used as a hostname.

Unexporting the referral object has the effect of removing the referral locations information from the referral object. Unexporting the referral object does not remove the referral object itself. The object can be removed using **rm** if desired. The administrator must ensure that appropriate data is available at the referral servers.

This option is available only on AIX version 5.3.0.30 or later, and is allowed only for version 4 exports. If the export specification allows version 2 or version 3 access, an error message will be printed and the export will be disallowed.

Note: A referral export can only be made if replication is enabled on the server. Use **chnfs -R on** to enable replication.

| Entry | Definition |
|--|--|
| <i>Option</i> (continued) | |
| replicas = <i>rootpath@host</i> [<i>+host</i>][: <i>rootpath@host</i> [<i>+host</i>]] | <p>Replica location information is associated with the export path. The replica information can be used by NFS version 4 clients to redirect operations to the specified alternate locations if the current server becomes unavailable. You should ensure that appropriate data is available at the replica servers. Since replica information applies to an entire file system, the specified path must be the root of a file system. If the path is not a file system root, the export is not allowed and an error message is printed. The name localhost cannot be used as a hostname.</p> <p>If the directory being exported is not in the replica list, the entry <i>ExportedDirectory@CurrentHost</i> is added as the first replica location. A replica export can only be made if replication is enabled on the server. By default, replication is not enabled. If replica exports are made at system boot, replication should be enabled using chnfs -R on. Replica locations can also be specified for the <i>nfsroot</i>. The chnfs command must be used for this purpose. In this case, the command is chnfs -R host [<i>+ host</i>]. If the current host is not specified in the list, it will be added as the first replica host. The <i>rootpath</i> is not needed or allowed in this case. The reason is that the <i>nfsroot</i> is replicated only to the <i>nfsroots</i> of the specified hosts. The replication mode can only be changed if there are no active NFS version 4 exports. If the server's replication mode is changed, any filehandles issued by the server during the previous replication mode will not be honored by the server. This can cause application errors on clients with old filehandles. Care must be taken when changing the replication mode of the server. If possible, all client mounts to the server should be unmounted before the server's replication mode is changed. The replica location information associated with the directory can be changed by modifying the replica list and reexporting the directory. The new replica information will replace the old replica information.</p> <p>NFS clients are expected to refresh replica information on a regular basis. If the server changes the replica information for an export, it may take some time for the client to refresh its replica information. This is not a serious problem if new replica locations are added, since clients with old replica information will still have correct, though possibly incomplete, replica information. Removing replica information can be problematic since it can result in clients having incorrect replica information for some period of time. To aid clients in detecting the new information, exportfs attempts to touch the replicated directory. This will change the timestamps on the directory, which in turn causes the client to refetch the directory's attributes. This operation may not be possible, however, if the replicated file system is read-only. When changing replica information for a directory, you should be aware that there may be a period of time between the changing of the replica information and clients getting the new replica information.</p> <p>This option is available only on AIX version 5.3.0.30 or later, and is meaningful only for version 4 exports. If the option is used on an export that allows version 2 or version 3 access, the operation is allowed, but the replica information is ignored by the version 2 and version 3 servers.</p> |
| noauto | Accepts the replicas specification as-is. Does not automatically insert the primary hostname as one of the replica locations if it has not been specified. |

nfsroot and nfspublic

In order to allow the NFS server administrator to hide some detail of the local file system from clients, the **nfsroot** and **nfspublic** attributes were added to the NFS version 4 implementation. The **nfsroot** and **nfspublic** may be specified independently, but **nfspublic** must be a subdirectory of **nfsroot**. When the **nfsroot** is set, a local directory can be exported so that it appears to the client to be a subdirectory of the **nfsroot**. Restrictions must be placed on the exported directories in order to avoid problems:

- The **nfsroot** must not be "/".
- Either all version 4 exports must specify an external name, or none must specify an external name.
- The external name must start with the **nfsroot** name. For example, if the **nfsroot** has been set to **/export/server**, the directory **/export/server/abc** can be used as an external name, but the directory **/abc** cannot be used as an external name. In this example, the **/tmp** directory might be exported as **/export/server/tmp**, but **/tmp** cannot be exported as **/xyz**.
- If the **-exname** option is used, only one directory can be exported per file system.
- If a directory is exported with an external name, any descendant of that directory that is also exported must maintain the same path between the two directories. For example, if **/a** is exported as

/export/dira, the directory **/a/b/c/d** can only be exported as **/export/dira/b/c/d**, provided **/a** and **/a/b/c/d** are different file systems or members of different file systems.

- If a directory is exported with an external name, any parent of that directory that is also exported must maintain the same path between the two directories. For example, if **/a/b** is exported as **/export/a/b**, the directory **/a** can only be exported as **/export/a**, provided **/a** and **/a/b** are different file systems or members of different file systems. Also, if **/a/b** is exported as **/export/b**, the directory **/a** cannot be exported because it does not exist in the path from the root node to export a pathname of **/b**.
- The **exportfs** command will only allow the **exname** option when the **-vers=4** options is also present.

Administration of **nfsroot**, **nfspublic**, and replication is performed using the **chnfs** command.

Examples

1. To export to **netgroup** clients, enter:

```
/usr -access=clients
```

2. To export to the world, enter:

```
/usr/local
```

3. To export to only these systems, enter:

```
/usr2 -access=hermes:zip:tutorial
```

4. To give root access only to these systems, enter:

```
/usr/tps -root=hermes:zip
```

5. To convert client root users to guest UID=100, enter:

```
/usr/new -anon=100
```

6. To export read-only to everyone, enter:

```
/usr/bin -ro
```

7. To allow several options on one line, enter:

```
/usr/stuff -access=zip,anon=-3,ro
```

8. To create a referral at **/usr/info** to the **/usr/info** directory on the host **infoserver**, add the following line to **/etc(exports** and then export **/usr/info**:

```
/usr/info -vers=4,refer=/usr/info@infoserver
```

9. To specify replicas for the directory **/common/info** at hosts **backup1** and **backup2**, add the following line to **/etc(exports** and then export **/common/info**:

```
/common/info -vers=4,replicas=/common/info@backup1:/common/info@backup2,<other options>
```

Files

filesystems File

Purpose

Centralizes file system characteristics.

Description

A file system is a complete directory structure, including a root (**/**) directory and any directories and files beneath it. A file system is confined to a logical volume. All of the information about the file system is centralized in the **/etc/filesystems** file. Most of the file system maintenance commands take their defaults from this file. The file is organized into stanza names that are file system names and contents that are attribute-value pairs specifying characteristics of the file system.

The **filesystems** file serves two purposes:

- It documents the layout characteristics of the file systems.
- It frees the person who sets up the file system from having to enter and remember items such as the device where the file system resides, because this information is defined in the file.

Requirements:

1. Name and value pairs must have some form of indentation. For example, a space or a tab.
2. Blank spaces and comma characters are not allowed in the file system mount point. Commas are used only as delimiters for multiple values to a name.
3. Do not place text before or after quotation marks. For example, `dev=abc"/dev/fd0"def` is not allowed and will result in undefined behavior.

File System Attributes

Each stanza names the directory where the file system is normally mounted. The file system attributes specify all the parameters of the file system. The attributes currently used are:

| Attribute | Description |
|----------------|---|
| account | Used by the dodisk command to determine the file systems to be processed by the accounting system. This value can be either the True or False value. |
| boot | Used by the mkfs command to initialize the boot block of a new file system. This specifies the name of the load module to be placed into the first block of the file system. |
| check | Used by the fsck command to determine the default file systems to be checked. The True value enables checking while the False value disables checking. If a number, rather than the True value is specified, the file system is checked in the specified pass of checking. Multiple pass checking, described in the fsck command, permits file systems on different drives to be checked in parallel. |
| dev | Identifies, for local mounts, either the block special file where the file system resides or the file or directory to be mounted. System management utilities use this attribute to map file system names to the corresponding device names. For remote mounts, it identifies the file or directory to be mounted. |

| Attribute | Description |
|------------------|--|
| free | This value can be either true or false. Obsolete and ignored. |
| mount | Used by the mount command to determine whether this file system should be mounted by default. The possible values of the mount attribute are: |
| automatic | Automatically mounts a file system when the system is started. Unlike the true value, filesystems which are mounted with the automatic value are not mounted with the mount all command or unmounted with the umount all command. By default, the ' / ', ' /usr ', ' /var ', and ' /tmp ' filesystems use the automatic value. |
| false | This file system is not mounted by default. |
| readonly | Mounts a file system as a read-only file system. |
| removable | Mounts a file system as a removable file system. While open files are on it, a removable mounted file system works the same as a normally mounted file system. However, when no files are open, and no process has a current directory on the file system, all of the file system disk buffers in the file system are written to the medium, and the operating system cannot access the file system. |
| true | This file system is mounted by the mount all command. It is unmounted by the umount all command. The mount all command is issued during system initialization to mount automatically all such file systems. |
| nodename | Used by the mount command to determine which node contains the remote file system. If this attribute is not present, the mount is a local mount. The value of the nodename attribute should be a valid node nickname. This value can be overridden with the mount -n command. |
| options | Comma-separated list of keywords that have meaning specific to a file system type. The options are passed to the file system at mount time. |
| size | Used by the mkfs command for reference and to build the file system. The value is the number of 512-byte blocks in the file system. |
| type | Used to group related mounts. When the mount -t String command is issued, all of the currently unmounted file systems with a type attribute equal to the <i>String</i> parameter are mounted. |
| vfs | Specifies the type of mount. For example, vfs=nfs specifies the virtual file system being mounted is an NFS file system. |
| vol | Used by the mkfs command when initializing the label on a new file system. The value is a volume or pack label using a maximum of 6 characters. |
| log | The <i>LVName</i> must be the full path name of the filesystem logging logical volume name to which log data is written as this file system is modified. This is only valid for journaled file systems. |

Examples

The following is an example of a typical **/etc/filesystems** file:

Note: Modifying this file can cause several effects to file systems.

```

*
* File system information
*
default:
    vol      = "OS"
    mount    = false
    check    = false

/:
    dev      = /dev/hd4
    vol      = "root"
    mount    = automatic
    check    = true
    log      = /dev/hd8

/home:
    dev      = /dev/hd1
    vol      = "u"
    mount    = true

```

```

check      = true
log       = /dev/hd8

/home/joe/1:
    dev      = /home/joe/1
    nodename = vance
    vfs      = nfs

/usr:
    dev      = /dev/hd2
    vol      = "usr"
    mount   = true
    check   = true
    log     = /dev/hd8

/tmp:
    dev      = /dev/hd3
    vol      = "tmp"
    mount   = true
    check   = true
    log     = dev/hd8

```

Note: The asterisk (*) is the comment character used in the **/etc/filesystems** file.

Foreign File for BNU

Purpose

Logs contact attempts from unknown systems.

Description

The **/var/spool/uucp/.Admin/Foreign** file lists access attempts by unknown systems. The **/usr/sbin/uucp/remote.unknown** shell script appends an entry to the **Foreign** file each time a remote computer that is not listed in the local **/etc/uucp/Systems** file attempts to communicate with that local system.

Someone with root user authority can customize entries in the **Foreign** file to fit the needs of a specific site by modifying the **remote.unknown** shell script.

Examples

This is a sample entry in the **Foreign** file:

Wed Sep 20 20:38:22 CDT 1989: call from the system merlin

System `merlin`, which is not listed in the `/etc/uucp/Systems` file, attempted to log in September 20 at 20:38 hours (10:38 p.m.). BNU did not allow the unknown system to log in.

Files

| Item | Description |
|---|---|
| <code>/var/spool/uucp/.Admin/Foreign</code> | Specifies the path of the Foreign file. |
| <code>/etc/uucp/Permissions</code> | Describes access permissions for remote systems. |
| <code>/etc/uucp/Systems</code> | Describes accessible remote systems. |
| <code>/usr/sbin/uucp/remote.unknown</code> | Records contacts from unknown systems in the Foreign file. |
| <code>/var/spool/uucp/.Admin</code> directory | Contains BNU administrative files. |

.forward File

Purpose

Automatically forwards mail as it is received.

Description

When mail is sent to a local user, the `sendmail` command checks for the `$HOME/.forward` file. The `$HOME/.forward` file can contain one or more addresses or aliases. If the file exists, the message is not sent to the user. The message is sent to the addresses or aliases in the `.forward` file. For example, if user `mickey`'s `.forward` file on host `disney` contains:

```
donald@wonderful.world.disney
pluto
```

Copies of messages sent to `mickey` are forwarded to user `donald` on host `wonderful.world.disney`, and to `pluto` on the local system.

Note:

1. The addresses listed in the `.forward` file can be a comma-separated list of addresses; for example:
`donald@wonderful.world.disney, pluto`
2. Addresses can specify programs. The following example forwards a message to the `vacation` command:
`mickey, "|/usr/bin/vacation mickey"`
This example sends a message to user `mickey` and to the `vacation` program.
3. This file must be created by the user in the `$HOME` directory.

To stop forwarding mail, use the `rm` command to remove the `.forward` file from your home directory:
`rm .forward`

The `.forward` file is deleted. Incoming mail is delivered to the user's system mailbox.

Files

| Item | Description |

ftpaccess.ctl File

Purpose

Specifies FTP host access parameters.

Description

The */etc/ftpaccess.ctl* file is searched for lines that start with **allow:**, **deny:**, **readonly:**, **writeonly:**, **readwrite:**, **useronly:**, **grouponly:**, **herald:** and/or **motd:**. Other lines are ignored. If the file doesn't exist, then ftp access is allowed for all hosts. The **allow:** and **deny:** lines are for restricting host access. The **readonly:**, **writeonly:** and **readwrite:** lines are for restricting ftp reads (get) and writes (put). The **useronly:** and **grouponly:** lines are for defining anonymous users. The **herald:** and **motd:** lines are for multiline messages before and after login.

Syntax

The syntax for all lines in */etc/ftpaccess.ctl* are in the form:

keyword: value, value, ...

where one can specify one or more values for every keyword. One can have multiple lines with the same keyword. The lines in */etc/ftpaccess.ctl* are limited to 1024 characters and anything greater than 1024 characters will be ignored. The syntax for the **allow:** and **deny:** lines are:

allow: host, host, ... **deny:** host, host, ...

If an **allow:** line is specified, than only the hosts listed in all the **allow:** lines are allowed ftp access. All other hosts will be refused ftp access. If there are no **allow:** line(s), then all hosts will be given ftp access except those hosts specified in the **deny:** line(s). The host can be specified as either a hostname or IP address.

The syntax for the **readonly:**, **writeonly:** and **readwrite:** lines are:

readonly: dirname, dirname, ... **writeonly:** dirname, dirname, ... **readwrite:** dirname, dirname, ...

The **readonly:** lines list the readonly directories and the **writeonly:** lines list the writeonly directories. If one wants read access in a writeonly directory or if one wants write access in a readonly directory, then access is denied. All other directories are granted access except when a **readwrite:** line(s) is specified. If a **readwrite:** line(s) is specified, only directories listed in the **readwrite:** line and/or listed in the **readonly:** line are granted access for reading, and only directories listed in the **readwrite:** line and/or listed in the **writeonly:** line are granted access for writing. Also, these lines can have a value of ALL or NONE.

The syntax for the **useronly:** and **grouponly:** lines are:

useronly: username, username, ... **grouponly:** groupname, groupname, ...

The username is from */etc/passwd* and the groupname is from */etc/group*. The **useronly:** line defines an anonymous user. The **grouponly:** line defines a group of anonymous users. These anonymous users are similar to the user anonymous in that ftp activity is restricted to their home directories.

The syntax for the **herald:** and **motd:** lines are:

```
herald: path motd: on|off
```

The path is the full path name of the file that contains the multiline herald that will be displayed before login. When the **motd:** line has a value of ON, then the **\$HOME/motd** file contains the multiline message that will be displayed after login. If the user is a defined anonymous user, then the **/etc/motd** file contains the multiline message that will be displayed after login. (Note that **/etc/motd** is in the anonymous user's chroot'ed home directory). The default for the **motd:** line is OFF.

/etc/group File

Purpose

Contains basic group attributes.

Description

The **/etc/group** file contains basic group attributes. This is an ASCII file that contains records for system groups. Each record appears on a single line and is the following format:

Name:Password:ID:User1,User2,...,Usern

You must separate each attribute with a colon. Records are separated by new-line characters. The attributes in a record have the following values:

| Attribute | Description |
|------------------------------|---|
| <i>Name</i> | Specifies a group name that is unique on the system. See the mkgroup command for information on the restrictions for naming groups. |
| <i>Password</i> | Not used. Group administrators are provided instead of group passwords. See the /etc/security/group file for more information. |
| <i>ID</i> | Specifies the group ID. The value is a unique decimal integer string. The maximum value is 4,294,967,295 (4 GB). |
| <i>User1,User2,...,Usern</i> | Identifies a list of one or more users. Separate group member names with commas. Each user must already be defined in the local database configuration files. |

Do not use a : (colon) in any of the attribute fields. For an example of a record, see the "Examples" section . Additional attributes are defined in the **/etc/security/group** file.

Note: Certain system-defined group and user names are required for proper installation and update of the system software. Exercise care before replacing the **/etc/group** file to ensure that no system-supplied groups or users are removed.

You should access the **/etc/group** file through the system commands and subroutines defined for this purpose. You can use the following commands to manage groups:

- **chgroup**
- **chgrpmem**
- **chuser**
- **lsgroup**
- **mkgroup**
- **mkuser**
- **rmgroup**

To change the *Name* parameter, you first use the **mkgroup** command to add a new entry. Then, you use the **rmgroup** command to remove the old group. To display all the attributes in the file, use the **lsgroup** command.

You can use the **chgroup**, **chgrpmem**, or **chuser** command to change all user and group attributes. The **mkuser** command adds a user whose primary group is defined in the **/usr/lib/security/mkuser.default** file and the **rmuser** command removes a user. Although you can change the group ID with the **chgroup** command, this is not recommended.

The following table lists all the possible group names and what functions the group controls.

| Group name | Description |
|------------|---|
| system | This group is used for configuration and maintenance for hardware and software. |
| printq | This group is used for managing queuing functions such as, enable, disable, qadm, and qpri. |
| security | This group is used for handling password and limits control. |
| adm | This group is used for monitoring functions such as, performance, cron, and accounting. |
| staff | This group is the default group assigned to all new users. |
| audit | This group is used for auditing. |
| shutdown | This group allows users access to the shutdown command. |
| bin | This group is used for the system internal group. |
| sys | This group is used for the system internal group. |
| uucp | This group manages the UUCP system. |
| mail | This group allows users to access the mail command. |
| cron | This group allows users to access the crontab command. |
| nobody | This group is for user that do not own any files and can be used as the default user for unprivileged operations. |
| kmem | This group allows users virtual memory read and write access such as, /dev/mem, /dev/port, and /dev/kmem. |
| log | This group allows users access to log files in /var/log. |
| lp | This group allows users access to the lp command. |
| network | This group allows users access to use the NetworkManager functions such as NM-Applet and KNetworkManager. |
| power | This group allows users access to suspend power. |
| root | This group allows users access to all system functions. |
| tty | This group allows users access to serial and USB devices. |
| users | This group is the default users group. This is the recommended group name you should use for users. |

Security

Access Control: This file should grant read (r) access to all users and grant write (w) access only to the root user and members of the security group.

Examples

A typical record looks like the following example for the staff group:

```
staff:!:1:shadow,cjf
```

In this example, the *GroupID* parameter is 1 and the users are defined to be shadow and cjf.

Files

/etc/security/group File

Purpose

Contains extended group attributes.

Description

The **/etc/security/group** file contains extended group attributes. This is an ASCII file that contains a stanza for each system group. Each stanza is identified by a group name from the **/etc/group** file followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute pair ends with a new-line character as does each stanza. The file supports a default stanza. If an attribute is not defined for a group, the default value for the attribute is used.

A stanza can contain one or more of the following attributes:

| Attribute | Description | | | | |
|-------------------|---|-------------|--|--------------|--|
| adms | Defines the group administrators. Administrators are users who can perform administrative tasks for the group, such as setting the members and administrators of the group. This attribute is ignored if admin = true , since only the root user can alter a group defined as administrative. The value is a list of comma-separated user login-names. The default value is an empty string. | | | | |
| admin | Defines the administrative status of the group. Possible values are: <table border="0"> <tr> <td>true</td> <td>Defines the group as administrative. Only the root user can change the attributes of groups defined as administrative.</td> </tr> <tr> <td>false</td> <td>Defines a standard group. The attributes of these groups can be changed by the root user or a member of the security group. This is the default value.</td> </tr> </table> | true | Defines the group as administrative. Only the root user can change the attributes of groups defined as administrative. | false | Defines a standard group. The attributes of these groups can be changed by the root user or a member of the security group. This is the default value. |
| true | Defines the group as administrative. Only the root user can change the attributes of groups defined as administrative. | | | | |
| false | Defines a standard group. The attributes of these groups can be changed by the root user or a member of the security group. This is the default value. | | | | |
| dce_export | Allows the DCE registry to overwrite the local group information with the DCE group information during a DCE export operation. Possible values are: <table border="0"> <tr> <td>true</td> <td>Local group information will be overwritten.</td> </tr> <tr> <td>false</td> <td>Local group information will not be overwritten.</td> </tr> </table> | true | Local group information will be overwritten. | false | Local group information will not be overwritten. |
| true | Local group information will be overwritten. | | | | |
| false | Local group information will not be overwritten. | | | | |

| Attribute | Description |
|----------------------------|---|
| efs_initialks_mode | Defines the initial mode of the group keystore. You can specify the following values: guard When a group keystore is in root guard mode, the keys contained in this keystore can be retrieved only with the correct access key of this keystore. admin When a keystore is in root admin mode, the keys contained in this keystore can be retrieved with the EFS (Encrypted File System) admin key. |
| | Notes: <ul style="list-style-type: none"> • This attribute is valid only if the system is EFS-enabled. • This attribute defines the initial mode of the keystore. Changing this value using the chuser command, the chgroup command, or the chsec command, or with manual editing, does not change the mode of the keystore. This attribute is used only when the keystore is created and is not used again until the keystore is deleted and a new one is created. To change the keystore mode, use the efskeymgr command. |
| efs_keystore_access | Defines the group keystore location. You can specify the following values: none There is no keystore. file Keystore is stored in the /var/efs/groups/ directory. Note: This attribute is valid only if the system is EFS-enabled. |
| efs_keystore_algo | Defines the algorithm that is used to generate the group private key. You can specify the following values: <ul style="list-style-type: none"> • RSA_1024 • RSA_2048 • RSA_4096 Notes: <ul style="list-style-type: none"> • This attribute is valid only if the system is EFS-enabled. • Changing the value of this attribute using the chuser command, the chgroup command, or the chsec command, or with manual editing, does not regenerate the private key. This attribute is used only when the keystore is created and is not used again until the keystore is deleted and a new one is created. To change the algorithm for the keys, use the efskeymgr command. |
| projects | Defines the list of projects that the user's processes can be assigned to. The value is a list of comma-separated project names and is evaluated from left to right. The project name should be a valid project name as defined in the system. If an invalid project name is found in the list, it will be reported as an error by the group commands. |

For a typical stanza, see the "Examples" section:

You should access the **/etc/security/group** file through the system commands and subroutines defined for this purpose. You can use the following commands to manage groups:

- **mkgroup**
- **chgroup**
- **chgrpmem**
- **lsgroup**
- **rmgroup**

The **mkgroup** command adds new groups to the **/etc/group** file and the **/etc/security/group** file. Use this command to create an administrative group. You can also use the **mkgroup** to set the group administrator.

Use the **chgroup** command to change all the attributes. If you are an administrator of a standard group, you can change the **adms** attribute for that group with the **chgrpmem** command.

The **lsgroup** command displays both the **adms** and the **admin** attributes. The **rmgroup** command removes the entry from both the **/etc/group** file and the **/etc/security/group** file.

To write programs that affect attributes in the **/etc/security/group** file, use the subroutines listed in Related Information.

Security

Access Control: This file should grant read (r) access to the root user and members of the security group, and to others as permitted by the security policy for the system. Only the root user should have write (w) access.

Auditing Events:

| Event | Information |
|---------------|-------------|
| S_GROUP_WRITE | file name |

Examples

A typical stanza looks like the following example for the finance group:

```
finance:
    admin = false
    adms = cjf, scott, sah
```

Files

| Item | Description |
|----------------------------|--|
| /etc/security/group | Specifies the path to the file. |
| /etc/group | Contains the basic attributes of groups. |
| /etc/passwd | Contains the basic attributes of users. |
| /etc/security/passwd | Contains password information. |
| /etc/security/user | Contains the extended attributes of users. |
| /etc/security/environ | Contains the environment attributes of users. |
| /etc/security/limits | Contains the process resource limits of users. |
| /etc/security/audit/config | Contains audit system configuration information. |
| /etc/security/lastlog | Contains last login information. |

Related information:

chgroup command
chgrpmem command
setgroups command
enduserdb subroutine

Workload Manager groupings File

Purpose

Defines attribute value groupings along with their associated values.

Description

The attribute value **groupings** file is in the configuration directory. It resides along with the **rules** file in the **SuperConf** and **SubConf** directories.

The attribute value **groupings** file is formatted as a flat ASCII file list with attribute grouping names followed by an equal (=) sign and the list of all attribute values in the group, separated by commas. The list of attribute values will be terminated by a carriage return. The list of attribute values can be continued onto multiple lines by preceding carriage returns with a backslash. The only whitespace that is

significant in the **groupings** file is a carriage return. Other whitespace characters are removed during file parsing. Comments are lines preceded by an asterisk.

Each attribute grouping definition is limited to **WLM_GROUPING_LEN** characters. The attribute grouping name and the list of attribute values cannot be an empty string.

Use of Attribute Groupings

Attribute groupings can be used as element of a selection criteria in the **rules** file for superclasses or subclasses. The attribute grouping name must be preceded by a dollar sign (\$) and will be replaced by the list of all attribute values associated with itself. No special character (*, [, -, ?, +]) except exclusion character '!' can be applied to an attribute grouping name. Attribute groupings cannot be used in the **class** field.

```
"rules" files:  
* class resvd user           group      application      type tag  
classA -   $trusted,!$nottrusted -         -          -      -  
classB -   -                   -         $shell,!/bin/zsh -      -  
classC -   -                   $rootgroup -
```

Syntax

The syntax of the attribute values is the same as in the **rules** file, including potential wildcards ([,]*,-,?,+). The use of the exclusion character '!' in the attribute values list is not allowed. This restriction is necessary to avoid a confusing interpretation of an attribute value grouping used in the **class** assignment file preceded by an exclusion character. Syntax is checked only when attribute groupings are used (rules processing during a configuration load or explicit check with **wlmcheck** command). The **groupings** file is not mandatory. By default, no attribute grouping is defined. Attribute value groupings of a **groupings** file are defined and usable only in the scope of their configuration directory (**SuperConfDir** or **SubConfDir** level). If it exists, the **groupings** file is copied in the **.running** directory when the configuration is loaded into the kernel as it is done with other configuration files. No command interface is provided to update the attribute **groupings** file.

Example

```
"groupings" file:  
* attribute groupings definition  
* will be used in the rules file  
trusted = user[0-9][0-9],admin*  
nottrusted = user23, user45  
shell=/bin/?sh,\  
       /bin/sh,\  
       /bin/tcsh  
rootgroup=system,bin,sys,security,cron,audit
```

"Workload Manager rules File" on page 370

hostmibd.conf File

Purpose

Defines the configuration parameters for **hostmibd dpi2** sub-agent.

Description

The **hostmibd.conf** file provides the configuration information for the **hostmibd dpi2** sub-agent. This file can be changed while the **hostmibd dpi2** sub-agent is running. If the **refresh** command is issued, the **hostmibd dpi2** sub-agent will reread this configuration file. The **hostmibd dpi2** sub-agent must be under System Resource Control (SRC) for the **refresh** command to force the reread. To accomplish the reread, as root user, run:

```
# refresh -s hostmibd
```

Keywords

The directives are specified in the form of <keyword>=<value>. The keyword is case-insensitive. The value passed is also case-sensitive.

LogFilename

The name of the most recent log file. Less recent log files have the number 1 to (n - 1) appended to their names. The larger the number, the less recent the file.

logFileSize

The Size of log files in K bytes. Maximum size of a log file. When the size of the most recent log file reaches this value, it is renamed and a new log file is created.

numLogFiles

The number of log files desired. The maximum value for **numLogFile**s is 4. A new file is created when the size of the log file is equal or more than the size specified by the keyword **logFileSize**. When the number of log files reaches the **numLogFile**s the log files start rotating.

requestTimeout

The timeout in seconds that the **snmpd** agent will wait for a response from this sub-agent. The default value is 60 seconds.

tracelevel

The tracing/debug level to do.

| |
|------------------------|
| 0 = Least level |
| 8 = DPI level 1 |
| 16 = DPI level 2 |
| 32 = Internal level 1 |
| 64 = Internal level 2 |
| 128 = Internal level 3 |

Add the numbers for multiple trace levels.

updateInterval

The interval, in seconds, that the sub-agent will use to refresh its internal table. The default value is 30 seconds.

Example

```
logFileName=/usr/tmp/hostmibd.log  
logFileSize=0  
numLogFile=0  
requestTimeout=180  
tracelevel=0  
updateInterval=120
```

image.data File

Purpose

Contains information on the image installed during the Base Operating System installation process.

Description

The **image.data** file contains information describing the image installed during the BOS installation process. This information includes the sizes, names, maps, and mount points of logical volumes and file systems in the root volume group. The **mkszfile** command generates the **image.data** file. It is not recommended that the user modify the file. Changing the value of one field without correctly modifying any related fields can result in a failed installation and a corrupted backup image. The only exception to this recommendation is the SHRINK field, which the user may modify to instruct the BOS installation routines to create the file systems as specified in the **image.data** file or to create the file systems only as large as is required to contain all the data in the file system.

The BOS installation process also takes input from the **image.data** file regarding defaults for the machine being installed. Any default values in the **image.data** file will override values obtained when the BOS installation queries the hardware topology and existing root volume group. The **image.data** file resides in the / directory.

This file is part of System Backup and BOS Install Utilities.

The **image.data** file is arranged in stanza format. Each stanza contains one or more fields. These stanzas include the following:

- image_data
- logical_volume_policy
- ils_data
- vg_data
- source_disk_data
- lv_data
- fs_data
- post_install_data
- post_restvg

image_data Stanza

| Field | Description |
|--------------|---|
| IMAGE_TYPE | Identifies the format of the image. Examples include backup file format (bff) and tar format. |
| DATE_TIME | Contains the date and time that the image was taken. |
| UNAME_INFO | Identifies the system and system level data associated with the image. |
| PRODUCT_TAPE | Specifies whether the image is a product image or a mksysb image. The possible field values are yes or no. |
| USERVG_LIST | Lists the user volume groups defined in the system. |
| OSLEVEL | Identifies the version.release.maintenance.fix level of the system at the time the image was taken |

Note: The PRODUCT_TAPE and USERVG_LIST fields are only present for the ROOTVG volume group.

logical_volume_policy Stanza

| Field | Description |
|-----------|--|
| SHRINK | Instructs BOS install routines to create the file systems as they are specified in the image.data file or create the smallest file systems required to contain all the data in the file system. The field value specified can be yes (shrink file systems) or no (use image.data file specifications). |
| EXACT_FIT | The field value specified can be yes or no. If yes is specified, the disk information listed in the source_disk_data stanza must match the actual disks found on the target machine during installation. |

ils_data Stanza

| Field | Description |
|-------|--|
| LANG | Sets the language used by the BOS Install program. |

vg_data Stanza

Note:

1. The **image.data** file can contain only one vg_data stanza.

| Field | Description |
|---------------------|---|
| VGNAME | Specifies the volume group name. |
| PPSIZE | Specifies the size of the physical partition for the volume group. |
| VARYON | Activates the volume group and all associated logical volumes so that the volume group is available for use. The field value can be yes or no. |
| VG_SOURCE_DISK_LIST | Lists the disks in the volume group. |
| QUORUM | If set to 1, indicates the volume group is to be automatically varied off after losing its quorum of physical volumes. |
| CONC_AUTO | Indicates a volume group is to be varied on automatically in concurrent mode. |
| BIGVG | Indicates a volume group is to be created as a big vg format volume group. This can accommodate up to 128 physical volumes and 512 logical volumes. |
| TFATOR | Indicates a change in the limit of the number of physical partitions per physical volume. |
| ENH_CONC_CAPABLE | Indicates a volume group is enhanced concurrent capable. |

source_disk_data Stanza

Note: The **image.data** file contains one source_disk_data stanza for each disk in the root volume group.

| Field | Description |
|------------|--|
| PVID | Specifies the 16 digit physical volume identifier for the disk. |
| CONNECTION | Specifies the combination of the parent and the connwhere attribute associated with a disk. The format for this field is: <i>parent attribute//connwhere attribute</i> . |
| LOCATION | Specifies the locations of the disks in the root volume group. |
| SIZE_MB | Specifies the size, in MB, of the disks in the root volume group. |
| HDISKNAME | Specifies the names of the disks in the root volume group. |

lv_data Stanza

Note: The **image.data** file contains one lv_data stanza for each logical volume created on the system.

| Field | Description |
|--------------------------|---|
| VOLUME_GROUP | Specifies the logical volume group name. Volume group names must be unique, system wide, and can range from 1 to 15 characters. |
| LV_SOURCE_DISK_LIST | Lists the disks in the logical volume. |
| LV_IDENTIFIER | Contains the identifier of the logical volume. |
| LOGICAL_VOLUME | Contains the name of the logical volume. |
| PERMISSION | Sets the access permissions. The field value can be read/write or read only . |
| VG_STAT | Indicates the state of the volume group. If the volume group is activated with the varyonvg command, the value of the VG_STAT field is either active/complete or active/partial . An active/complete field value indicates that all physical volumes are active, while an active/partial field value indicates that all physical volumes are not active. If the volume group is not activated with the varonvg command, the VG_STAT field value is inactive . |
| TYPE | Describes the logical volume type. |
| MAX_LPS | Sets the maximum number of logical partitions within the logical volume. |
| COPIES | Specifies the number of physical partitions created for each logical partition during the allocation process. |
| LPS | Specifies the number of logical partitions currently in the logical volume. |
| STALE_PPs | Specifies the number of physical partitions in the logical volume that are not current. |
| INTER_POLICY | Specifies the inter-physical allocation policy. The field value can be minimum or maximum . |
| INTRA_POLICY | Specifies the intra-physical allocation policy. The possible field values are either middle , center , or edge . |
| MOUNT_POINT | Specifies the file-system mount point for the logical volume, if applicable. |
| MIRROR_WRITE_CONSISTENCY | Specifies mirror-write consistency state. The field value can be off or on . |
| LV_SEPARATE_PV | Specifies a yes , no , or super field value for strict allocation. A yes value for strict allocation states that no copies for a logical partition are allocated on the same physical volume. A no value for strict allocation (non-strict) states that at least one occurrence of two physical partitions belong to the same logical partition. A super value for strict allocation (super strictness) states that no partition from one mirror copy may reside on the same disk as another mirror copy. |
| LV_STATE | Describes the state of the logical volume. An Opened/stale value indicates the logical volume is open but contains physical partitions that are not current. An Open/syncd value indicates the logical volume is open and its physical partitions are current, or synchronized. A Closed value indicates the logical volume has not been opened. |
| WRITE_VERIFY | Specifies the field value of the write verify state as on or off . |
| PP_SIZE | Provides the size physical partition. |
| SCHED_POLICY | Specifies a sequential or parallel scheduling policy. |
| PP | Specifies the number of physical partitions currently in the logical volume. |
| BB_POLICY | Specifies the bad block relocation policy. |
| RELOCATABLE | Indicates whether the partitions can be relocated if a reorganization of partition allocation takes place. The field value can be yes or no . |
| UPPER_BOUND | Specifies the maximum number of physical volumes for allocation. |
| LABEL | Specifies the label field for the logical volume. |
| MAPFILE | Provides the full path name to a map file to be used in creating the logical volume. |
| LV_MIN_LPS | Specifies the minimum size of the logical volume to use when shrinking the logical volume. |
| STRIPE_WIDTH | Specifies the number of physical volumes being striped across. |

| Field | Description |
|--------------|---|
| STRIPE_SIZE | Specifies the number of bytes per stripe. Stripe size multiplied by the number of disks in the array equals the stripe size. The field value must be a power of two, between 4KB and 128MB; for example, 4KB, 8KB, 16KB, 32KB, 64KB, 128KB, 256KB, 512KB, 1MB, 2MB, 4MB, 8MB, 16MB, 32MB, 64MB, or 128MB. |
| SERIALIZE_IO | Turns on/off serialization of overlapping IOs. If serialization is turned on, then overlapping IOs are not allowed on a block range and only a single IO in a block range is processed at any one time. Most applications (file systems and databases) do serialization, so serialization should be turned off. |

fs_data Stanza

| Field | Description |
|-----------------------|--|
| FS_NAME | Specifies the mount point of the file system. |
| FS_SIZE | Specifies the size, in 512-byte blocks, of the file system. |
| FS_MIN_SIZE | Specifies the minimum size required to contain the files of the file system. This size is used when the SHRINK field in the logical_volume_policy stanza has a field value of yes. |
| FS_LV | Provides the logical volume name. The name must contain the /dev/ prefix. An example of an appropriate name is /dev/hd4. |
| FS_FS | Specifies the fragmentation size of the system. This value is optional. |
| FS_NBPI | Specifies the number of bytes per i-node. This value is optional. |
| FS_COMPRESS | Designates whether the file system should be compressed or not. The field value can be LZ, which compresses the file system, or the no field value. |
| FS_BF | Enables the file system for files greater than 2 GB. The possible values are true or false. |
| FS_AGSIZE | Specifies the allocation group size. The possible values are 8, 16, 32, or 64. The allocation group size is specified in units of megabytes. |
| FS_JFS2_BS | Specifies the file system block size in bytes, 512, 1024, 2048, or 4096 bytes. |
| FS_JFS2_SPARSE | Specifies when files are created with holes. The enhanced journaled file system (JFS2) allocates disk blocks for those holes and fills the holes with 0s. |
| FS_JFS2_INLINELOG | Specifies that the journal log for the enhanced journaled file system (JFS2) is within the file system. |
| FS_JFS2_SIZEINLINELOG | Specifies the size, in megabytes, for the optional inline journal log. The default is the size of the enhanced journaled file system (JFS2) divided by 256. |
| FS_JFS2_EFS | Specifies whether a file system must be created as an Encrypted File System (EFS). |
| FS_JFS2_EFORMAT | Specifies whether a file system should be created with extended attributes. |
| FS_JFS2_QUOTA | Specifies whether file and block-usage statistics should be maintained and whether limits should be enforced by the file system. |
| FS_JFS2_DMAPI | Specifies whether a file system is managed. |
| FS_JFS2_VIX | Specifies whether a file system can allocate i-node smaller than the default. |

post_install_data Stanza

| Field | Description |
|--------------|--|
| BOSINST_FILE | Provides the full path name of a file or command to execute after BOS install completes. |

post_restvg Stanza

| Field | Description |
|-------------|--|
| RESTVG_FILE | Specifies the full path name of the file or command to execute after the restvg process completes. |

Note: The post_install_data stanza exists for the ROOTVG volume group and the post_restvg stanza is present for other volume groups.

/etc/security/.ids File

Purpose

Contains standard and administrative user IDs and group IDs.

Description

The /etc/security/.ids file keeps a count so that every UID (userid) and GID (groupid) has its own unique number. It is not recommended that you edit this file unless it is absolutely necessary.

Example

7 201 11 200

The first number in the example (7) will be the User ID of the next administrative user created on the system. The second number (201) will be the User ID of the next regular user created on the system. The third number (11) is the next administrative Group ID (GID) that will be used when an administrative user is created on the system. The fourth number (200) is the next regular user GID used when a user is created.

Location

| Item | Description |
|--------------------|----------------------------|
| /etc/security/.ids | Location of the .ids file. |

INed Files

Purpose

Contains programs and data used by the INed program.

Description

The /usr/lib/INed directory contains a number of files and subdirectories used internally by the INed program. The /usr/lib/nls/msg/\$LANG directory contains files of translatable text. This directory also contains other files that are not used by INed.

In the following file names, **\$LANG** is the value of the **lib/Language** environment variable, which indicates the national language currently being used.

| Item | Description |
|---|---|
| bin | Directory containing programs called by the editor to perform various functions. Do not run these programs from the command line. |
| FATAL.LOG | Log of error messages the editor records when it encounters a system problem. |
| helpers | Directory containing programs called by the editor to help work on certain kinds of data. Files ending in .x or named x use the helper named x.help . Helpers typically supply the functions listed on the INed local menus. |
| forms | Directory containing forms used by the INed program. Files ending in .x or named x use the x.ofm form. The forms are binary files used directly by the editor in generating displays for structured files. |
| /usr/lib/nls/msg/\$LANG/keys.map | File displayed when the Help command key (F1) is pressed and the keymap option is selected. |
| termcap | Directory containing the files used by the editor to read input from the terminals and write output to the terminals. The def.trm file is the readable structured file, and the terms.bin file is the compressed version. |
| /usr/lib/nls/msg/\$LANG | Directory containing help message files and other files containing translated text used by the INed editor. This directory also contains other files not used by INed. |

Files

| Item | Description |
|--|---|
| /usr/lib/INed directory | Contains files and subdirectories used by the INed program. |
| /usr/lib/nls/msg/\$LANG directory | Contains files of translatable text. |

.info File

Purpose

Stores configuration information used by the Network Install Manager (NIM).

Description

The **.info** file contains a series of Korn shell variable assignments used by NIM. The **.info** file is created by NIM for each client. During network boot, the **rc.boot** program uses several of these variables to control processing.

If a client is initialized by NIM, the **.info** file is copied into that client's **/etc** directory as the **/etc/niminfo** file. The **nimclient** command uses the **/etc/niminfo** file to communicate with the NIM master server.

Note: The following variable groups are based upon the function of the variables that they contain. The **.info** file itself is not divided into categories.

Variables used directly by the rc.boot program

| Variable | Description |
|-----------|---|
| ROUTES | Contains all the routing information the client needs in order to access any allocated NIM resource. This information is presented as a series of space-separated stanzas, each in the following format: <i>DestinationIPAddress:DestinationSubnet :GatewayIPAddress</i> |
| SPOT | Specifies the location of the shared product object tree (SPOT) to be used during the boot process. This variable contains the host and pathname of the client's SPOT in the following format: <i>HostName:SPOTDirectory</i> |
| RC_CONFIG | Specifies the file name of the rc.config script to use. |
| NIM_HOSTS | Provides information used to construct an /etc/hosts file for the client. The value is formatted as follows: <i>IPAddress:HostName IPAddress:HostName ...</i> |

Variables used by any rc.config script

| Variable | Description |
|----------|--|
| ROOT | Specifies the host and path name of the client's root directory in the following format: <i>HostName:RootDirectory</i> |
| MOUNTS | Contains a series of space-separated stanzas, each composed of a remote directory specification and the point where it should be mounted. The stanzas are in the following format: <i>HostName:RemoteDirectory:LocalDirectory</i> |

Variables used by the nim commands

| Variable | Description |
|-----------------------|--|
| NIM_NAME | Designates the name of the client's NIM machines object. |
| NIM_CONFIGURATION | Specifies the client's NIM configuration machine type. |
| NIM_MASTER | Specifies the IP address of the NIM master server. |
| NIM_MASTER_PORT | Specifies the port number to use for client communications. |
| NIM_REGISTRATION_PORT | Specifies the port number to use for client registration. |
| NIM_MAX_RETRIES | Specifies the maximum number of retries for communication attempts with the nimesis daemon. |
| NIM_MAX_DELAY | Sets the amount of time to wait between retries for communication with the nimesis daemon. |

Variables used by BOS Install

The following variables are used by NIM to control Base Operating System (BOS) installation operation:

| Variable | Description |
|------------------|--|
| NIM_BOSINST_DATA | Specifies the RAM file system path name to the bosinst.data file to be used. This variable has the following format: <i>Pathname</i> |
| NIM_BOS_IMAGE | Specifies the RAM file system path name to the BOS image. |
| NIM_CUSTOM | Specifies the path name of the customization script to execute after BOS installation. |

Variables used by the rc.dd_boot Script

The **rc.dd** script uses the following variables to perform boot specific processing to create certain NIM resources.

| Variable | Description |
|------------------|--|
| DTLS_PAGING_SIZE | Contains the paging-space size that you specify. If you have not set the paging space, the value is NULL and the <code>rc.dd_boot</code> script defaults to a paging space twice that of the client's RAM space. |
| DTLS_LOCAL_FS | Contains a list of acronyms specifying the filesystems to be created locally on the client. The possible values are <code>tmp</code> and <code>home</code> . |

Examples

The following is an example of a `.info` file:

```
#-----Network Install
Manager-----
# warning - this file contains NIM configuration information
#           and should only be updated by NIM
export NIM_NAME=dua
export NIM_CONFIGURATION=standalone
export NIM_MASTER_HOSTNAME=satu
export NIM_MASTER_PORT=1058
export NIM_REGISTRATION_PORT=1059
export RC_CONFIG=rc.bos_inst
export SPOT=tiga:/usr
export NIM_CUSTOM=/tmp/dua.script
export NIM_BOS_IMAGE=/SPOT
export NIM_BOS_FORMAT=master
export NIM_HOSTS=" 130.35.130.1:satu 130.35.130.3:tiga "
export MOUNTS=" tiga:/export/logs/dua:/var/adm/ras:dir
tiga:/export/nim/simages
:/SPOT/usr/sys/inst.images:dir
satu:/export/nim/scripts/dua.script:/tmp/dua.script:file "
```

Related information:

`lsnim` command
`nim` command
`niminit` command

inittab File

Purpose

Controls the initialization process.

Description

The `/etc/inittab` file supplies the script to the `init` command's role as a general process dispatcher. The process that constitutes the majority of the `init` command's process dispatching activities is the `/etc/getty` line process, which initiates individual terminal lines. Other processes typically dispatched by the `init` command are daemons and the shell.

The `/etc/inittab` file is composed of entries that are position-dependent and have the following format:

Identifier:RunLevel:Action:Command

Note: The colon character (:) is used as a delimiter as well as a comment character. To comment out an `inittab` entry, add : at the beginning of the entry. For example:

:Identifier:RunLevel:Action:Command

Each entry is delimited by a newline character. A backslash (\) preceding a newline character indicates the continuation of an entry. There are no limits (other than maximum entry size) on the number of entries in the `/etc/inittab` file. The maximum entry size is 1024 characters. The entry fields are:

Identifier

A string (one or more than one character) that uniquely identifies an object.

RunLevel

The run level in which this entry can be processed. Run levels effectively correspond to a configuration of processes in the system. Each process started by the **init** command is assigned one or more run levels in which it can exist. Run levels are represented by the numbers 0 through 9. For example, if the system is in run level 1, only those entries with a 1 in the *runlevel* field are started. When you request the **init** command to change run levels, all processes without an entry in the *runlevel* field for the target run level receive a warning signal (**SIGTERM**). There is a 20-second grace period before processes are forcibly terminated by the kill signal (**SIGKILL**). The *runlevel* field can define multiple run levels for a process by selecting more than one run level in any combination from 0 through 9. If no run level is specified, the process is assumed to be valid at all run levels.

There are three other values that appear in the *runlevel* field, even though they are not true run levels: **a**, **b**, and **c**. Entries that have these characters in the *runlevel* field are processed only when the **telinit** command requests them to be run (regardless of the current run level of the system). They differ from run levels in that the **init** command can never enter run level **a**, **b**, or **c**. Also, a request for the execution of any of these processes does not change the current run level. Furthermore, a process started by an **a**, **b**, or **c** command is not killed when the **init** command changes levels. They are only killed if their line in the **/etc/inittab** file is marked off in the *action* field, their line is deleted entirely from **/etc/inittab**, or the **init** command goes into single-user mode.

Action Tells the **init** command how to treat the process specified in the *identifier* field. The following actions are recognized by the **init** command:

respawn

If the process does not exist, start the process. Do not wait for its termination (continue scanning the **/etc/inittab** file). Restart the process when it dies. If the process exists, do nothing and continue scanning the **/etc/inittab** file.

wait When the **init** command enters the run level that matches the entry's run level, start the process and wait for its termination. All subsequent reads of the **/etc/inittab** file while the **init** command is in the same run level will cause the **init** command to ignore this entry.

once When the **init** command enters a run level that matches the entry's run level, start the process, and do not wait for its termination. When it dies, do not restart the process. When the system enters a new run level, and the process is still running from a previous run level change, the program will not be restarted. All subsequent reads of the **/etc/inittab** file while the **init** command is in the same run level will cause the **init** command to ignore this entry.

boot Process the entry only during system boot, which is when the **init** command reads the **/etc/inittab** file during system startup. Start the process, do not wait for its termination, and when it dies, do not restart the process. In order for the instruction to be meaningful, the run level should be the default or it must match the **init** command's run level at boot time. This action is useful for an initialization function following a hardware reboot of the system.

bootwait

Process the entry the first time that the **init** command goes from single-user to multi-user state after the system is booted. Start the process, wait for its termination, and when it dies, do not restart the process. If the **initdefault** is 2, run the process right after boot.

powerfail

Execute the process associated with this entry only when the **init** command receives a power fail signal (**SIGPWR**).

powerwait

Execute the process associated with this entry only when the **init** command receives a power fail signal (**SIGPWR**), and wait until it terminates before continuing to process the **/etc/inittab** file.

- off** If the process associated with this entry is currently running, send the warning signal (**SIGTERM**), and wait 20 seconds before terminating the process with the kill signal (**SIGKILL**). If the process is not running, ignore this entry.

ondemand

Functionally identical to **respawn**, except this action applies to the **a**, **b**, or **c** values, not to run levels.

initdefault

An entry with this action is only scanned when the **init** command is initially invoked. The **init** command uses this entry, if it exists, to determine which run level to enter initially. It does this by taking the highest run level specified in the *runlevel* field and using that as its initial state. If the *runlevel* field is empty, this is interpreted as 0123456789; therefore, the **init** command enters run level 9. Additionally, if the **init** command does not find an **initdefault** entry in the **/etc/inittab** file, it requests an initial run level from the user at boot time.

sysinit

Entries of this type are executed before the **init** command tries to access the console before login. It is expected that this entry will only be used to initialize devices on which the **init** command might try to ask the run level question. These entries are executed and waited for before continuing.

Command

A shell command to execute. The entire *command* field is prefixed with exec and passed to a forked sh as sh -c exec command. Any legal sh syntax can appear in this field. Comments can be inserted with the # comment syntax.

The **getty** command writes over the output of any commands that appear before it in the **inittab** file. To record the output of these commands to the boot log, pipe their output to the **alog -tboot** command.

The stdin, stdout and stdferr file descriptors may not be available while **init** is processing **inittab** entries. Any entries writing to stdout or stderr may not work predictably unless they redirect their output to a file or to **/dev/console**.

The following commands are the only supported method for modifying the records in the **/etc/inittab** file:

| Command | Purpose |
|---------------|--|
| chitab | Changes records in the /etc/inittab file. |
| lsitab | Lists records in the /etc/inittab file. |
| mkitab | Adds records to the /etc/inittab file. |
| rmitab | Removes records from the /etc/inittab file. |

Examples

1. To start the **ident** process at all run levels, enter:

```
ident:0123456789:Action:Command
```

2. To start the **ident** process only at run level 2, enter:

```
ident:2:Action:Command
```

3. To disable run levels 0, 3, 6-9 for the **ident** process, enter:

```
ident:1245:Action:Command
```

4. To start the **rc** command at run level 2 and send its output to the boot log, enter:

```
rc:2:wait:/etc/rc 2>&1 | alog -tboot >
/dev/console
```

Files

| Item | Description |
|-----------------|--|

isns_servers File

Purpose

Configures iSNS servers.

Description

The **isns_servers** file is used to configure iSNS servers. This file is used for the iSCSI target registration with iSNS protocol while configuring an iSCSI target. You can use comments in the **isns_servers** file. The comment character is "*", and must be the first character on the line. Blank lines are ignored.

The **isns_servers** file is a stanzas normalized file. Each stanza can be defined with the following two attributes:

- *ip_address* defines the IP address of the server.
- *port* defines the server listening port.

The **default** stanza defines the default *ip_address* and *port* that are used if one field is omitted.

The **registration_period** stanza allows you to set the refresh period for the iSNS registration. The iSNS server removes the registration after a period of time. A daemon has to refresh registrations before this lifetime. The period field of **registration_period** defines the period of time that an iSNS daemon can use. This setting is common for all iSNS servers that are defined in this file.

Examples

| Example configuration | Description |
|---|--|
| default: <i>ip_address</i> : auto <i>port</i> : 3205 registration_period: <i>period</i> : 120 myserver: <i>ip_address</i> : 172.16.128.4 isns_srv: <i>ip_address</i> : 172.16.128.108 <i>port</i> : 3206 | This configuration defines the following characteristics: <ul style="list-style-type: none">• A remote iSNS server (myserver) whose IP address is 172.16.128.4 and listens on the default iSNS server port 3205.• A remote iSNS server (isns_srv) whose IP address is 172.16.128.108 and listens on port 3206.• An iSNS daemon refreshes registrations with the iSNS server every 120 seconds. |

| Example configuration | Description |
|---|---|
| default: <i>ip_address</i> : 172.16.128.4 <i>port</i> : 3205 | This configuration defines the following characteristics: <ul style="list-style-type: none">• Two remote iSNS servers (myserver1 and myserver2) that both have the default IP address 172.16.128.4. myserver1 listens on the default iSNS server port 3205. myserver2 listens on port 3206.• A remote iSNS server (isns_srv) whose IP address is 172.16.128.108 and listens on port 3205.• An iSNS daemon refreshes registrations with the iSNS server every 900 seconds (or 15 minutes). |
| registration_period: <i>period</i> : 900 | |
| myserver1: | |
| myserver2: <i>port</i> : 3206 | |
| isns_srv: <i>ip_address</i> : 172.16.128.108 | |

Attention: Do not rename the following fields: default, ip_address, port, registration_period and period.

Files

| Item | Description |
|---------------------------|--------------------------|
| /etc/tmiscli/isns_servers | Configures iSNS servers. |

irs.conf File

Purpose

Specifies the ordering of certain name resolution services.

Description

The /etc/irs.conf file is used to control the order of mechanisms that the resolver libraries use in searching for network-related data. The following subroutines resolve host names, networks, services, protocols, and netgroups:

| Network Data | Subroutines |
|--------------|--|
| host names | <code>gethostbyname</code> , <code>gethostaddr</code> , <code>gethostent</code> |
| networks | <code>getnetbyname</code> , <code>getnetbyaddr</code> , <code>getnetent</code> |
| services | <code>getservbyname</code> , <code>getservbyaddr</code> , <code>getservent</code> |
| protocols | <code>getprotobynumber</code> , <code>getprotoaddr</code> , <code>getprotoent</code> |
| netgroups | <code>getnetgroupent</code> |

Because these subroutines are commonly used in many TCP/IP applications, using the **irs.conf** file can control the directions of the queries made by these applications as well.

By default, the subroutines use the lookup mechanisms to resolve host names in this order:

1. Domain Name Server (DNS)
2. Network Information Service (NIS), if active
3. local files

By default, the subroutines use the lookup mechanisms to resolve networks in this order:

1. DNS
2. NIS, if active
3. local files

By default, the subroutines use the lookup mechanisms to resolve other maps in this order:

1. NIS, if active
2. local files

You can override the default order by modifying the **/etc/irs.conf** configuration file and specifying the desired ordering.

The settings in the **/etc/netsvc.conf** configuration file override the settings in the **/etc/irs.conf** file. The **NSORDER** environment variable overrides the settings in the **/etc/irs.conf** and the **/etc/netsvc.conf** files.

To use DNS to obtain information concerning netgroups, protocols, and services, you must create and use a Hesiod DNS Zone in the following format:

map mechanism [option]

The following values are available for the *map* parameter:

| Value | Description |
|------------------|---|
| services | Lists the port numbers, transport protocols, and names of well-known services |
| protocols | Retrieves official names and protocol numbers of protocol aliases |
| hosts | Defines the mappings between host names and their IP addresses |
| networks | Retrieves network names and addresses |
| netgroup | Retrieves groups of hosts, networks, and users in this group |

The following values are available for the *mechanism* parameter:

| Value | Description |
|-----------------|---|
| local | Examines local configuration files (/etc/hosts , /etc/protocols , /etc/services , /etc/netgroup , and /etc/networks files) |
| dns | Queries DNS; the /etc/resolv.conf file must be configured for this mechanism to work. |
| nis | Queries NIS; the NIS client must be active on the system for this mechanism to work. |
| nis+ | Queries NIS+; The NIS+ client must be active on the system for this mechanism to work. |
| ldap | Queries the LDAP server; the resolv.ldap file must be configured for this mechanism to work. Note: You can only assign the value hosts to the <i>map</i> parameter for ldap . Although still supported, the use of the ldap mechanism is deprecated. Use of the nis_ldap mechanism is recommended. |
| nis_ldap | Queries the LDAP server configured in the ldap.cfg file. The LDAP client should be set up on the system using mksecdap command, to use this mechanism. All map types are supported by nis_ldap . |
| local4 | Examines local configuration files for IPv4 addresses. |
| local6 | Examines local configuration files for IPv6 addresses. |
| dns4 | Queries DNS for A records (IPv4 addresses); the /etc/resolv.conf file must be configured for this mechanism to work. |
| dns6 | Queries DNS for AAAA records (IPv6 addresses); the /etc/resolv.conf file must be configured for this mechanism to work. |
| nis4 | Queries NIS for information about IPv4 addresses; the NIS client must be active on the system to use this mechanism. |
| nis6 | Queries NIS for information about IPv6 addresses; the NIS client must be active on the system to use this mechanism. |
| ldap4 | Queries the LDAP server for information about IPv4 addresses. |
| ldap6 | Queries the LDAP server for information about IPv6 addresses. |

The following values are available for the *option* parameter:

| Value | Description |
|-----------------------|--|
| <code>continue</code> | If the information is not found in the specified mechanism, then instructs the resolver to continue to the next line, which should list another mechanism for the same map |
| <code>merge</code> | Merges all responses from multiple <i>mechanism</i> parameters into one response |

Examples

1. To use only the local **/etc/hosts** file for host name resolution, enter:

```
hosts local
```

2. To use the LDAP server to resolve a host name that cannot be found in the the **/etc/hosts** file, enter:

```
hosts local continue
hosts ldap
```

3. To use only DNS to resolve host names and to use NIS to resolve protocols, enter:

```
hosts dns
protocols nis
```

4. To use only NIS to resolve host name addresses and netgroups and to use the local files to resolve services and networks, enter:

```
hosts nis
services local
netgroup nis
networks local
```

5. To try to resolve host names from the local **/etc/hosts** file and, after not finding them, try to resolve from DNS, then NIS, enter:

```
hosts local continue
hosts dns continue
hosts nis continue
```

6. To try to resolve host names from the local **/etc/hosts** file, merge any information found with any DNS information found, and then merge this information to any NIS information found, enter:

```
hosts local merge
hosts dns merge
hosts nis
```

If the resolver finds no information, it returns none. If it finds information from more than one source, it returns that information as a merged response from all of the available sources.

7. To examine the local **/etc/services** file for port numbers before querying NIS, enter:

```
services local continue
services nis
```

This entry in the **/etc/irs.conf** file could speed up the request; normally, querying NIS takes more time than querying the local file. If the resolver does not find the information in the local file, it searches NIS.

8. To query for IPv4 network addresses only from DNS and to query IPv6 host addresses only from the local file, enter:

```
networks dns4
hosts local6
```

9. In this example, assume the following presuppositions:

- The **/etc/hosts** file contains the following information:

```
1.2.3.4 host4
1.2.3.5 host5
1.2.3.6 host6
```

- The information in DNS is the following:

```
1.2.3.2 host2
1.2.3.3 host3
```

- The information in NIS is the following:

```
1.2.3.1 host1
```

To instruct the **gethostbyname** subroutine to look for the host name first in the local configuration files, then to continue to search in DNS if the host name is not found, and finally to continue searching in NIS if the host name is not found, create the following entry in the **/etc/irs.conf** file:

```
hosts local continue
hosts dns continue
hosts nis
```

In this example, the **gethostbyname** subroutine cannot find the host name in the **/etc/hosts** file and continues to search for the host name in DNS. After not finding it in DNS, it continues to search in NIS. After finding the address in NIS, it returns 1.2.3.1.

10. In this example, assume the following presuppositions:

- The **/etc/hosts** file contains the following information:
1.1.1.1 hostname
- The information in DNS is the following:
1.1.1.2 hostname

To instruct the **gethostbyname** subroutine to merge all the answers from the specified mechanisms into one reply, create the following entry in the **/etc/irs.conf** file:

```
hosts local merge
hosts dns
```

The **gethostbyname** subroutine returns 1.1.1.1 1.1.1.2.

Files

| Item | Description |
|-------------------------|---|
| /etc/hosts | Contains the Internet Protocol (IP) name and addresses of hosts on the local network |
| /etc/protocols | Contains official names and protocol numbers of protocol aliases |
| /etc/services | Contains lists of the port numbers, transport protocols, and names of well-known services |
| /etc/netgroup | Contains a list of groups of hosts, networks, and users in these groups |
| /etc/networks | Contains a list of network names and addresses |
| /etc/resolv.conf | Contains Domain Name Protocol (DOMAIN) name-server information for local resolver subroutines |
| /etc/netsvc.conf | Specifies the ordering of certain name resolution services |

ispPaths File

Purpose

Defines the location of all databases in a library.

Description

The **ispPaths** file contains a block of information (a stanza) for each database in a library. A library consists of up to 63 standalone or cross-linked databases. The **ispPaths** file for the default database library resides

in the `/usr/lpp/info/data` directory. The **ispaths** files for other public libraries may reside in the `/usr/lpp/info/data/LibraryName` directory, and contain a stanza of information for each database in the library.

Each stanza must have the following format:

| Line | Explanation of Content |
|--|--|
| id <i>DatabaseNumber</i> | Represents the number of the database. This number can be between 0 and 1462, with a maximum of 1563 databases in a library. (Database number 1563 is reserved for the help database.) |
| primnav <i>TRUE</i> | Note: The order of databases in the ispaths file must match the order of databases in the dbnames file used during the build process. (Optional.) Indicates whether the database contains any of the primary navigation articles. The primnav line can be set to TRUE for only one database in the library. Omit this line unless its value is TRUE . |
| browse <i>TRUE</i> | (Optional.) Indicates whether the entire library is browse enabled with the browse button displayed in the reading window. Omit this line if its value is not TRUE . |
| glossary <i>TRUE</i> | (Optional.) Indicates whether the database contains glossary entries. The glossary line can be set to TRUE for only one database in the library. Omit this line unless its value is TRUE . |
| name <i>Database</i> | Specifies the name of the database. |
| title <i>DatabaseTitle</i> | Specifies the title that is assigned to the database. This title is displayed in the search results window (the Match Lists window) and the Database selection window helps users narrow their searches. |
| key <i>DatabasePath/DatabaseName.key</i> | Specifies the full path name of the database .key file. |
| rom <i>DatabasePath /DatabaseName.rom</i> | Specifies the full path name of the database .rom file. |

The optional field **browse** can be specified in any of the stanzas, and its value will be applied to the entire library. The **browse** field does not need to be specified in each stanza for each library that has browse capability.

Examples

The following is an example of an **ispaths** file for a sample database.

The **isprime** file for this database specifies these primary navigation articles:

- Commands
- System Calls
- Subroutines
- Special Files
- File Formats
- List of Tasks
- List of Books
- Education

All the top-level lists reside in the navigation database.

```
#####
#      info Navigation Database
#####
id      0
primnav TRUE
browse  TRUE
```

```

“**isprime** File”

isprime File

Purpose

Specifies the labels for links to primary navigation articles.

Description

The **isprime** file specifies labels for buttons located at the bottom of a navigation window. These button labels or menu options serve as links to the primary navigation articles. Labels for up to eight primary navigation articles can be defined in the **isprime** file. The text string that serves as the label or options can consist of any alphanumeric combination, including spaces.

The format for the **isprime** file is as follows:

- 1 *TextForFirstLink*
- 2 *TextForSecondLink*
- 3 *TextForThirdLink*
- 4 *TextForFourthLink*
- 5 *TextForFifthLink*
- 6 *TextForSixthLink*
- 7 *TextForSeventhLink*
- 8 *TextForEighthLink*

Examples

An **isprime** file for a sample database might look as follows:

- 1 Commands
- 2 System Calls
- 3 Subroutines
- 4 Special Files
- 5 File Formats
- 6 List of Tasks
- 7 List of Books
- 8 Education

.kshrc File

Purpose

Contains a shell script that customizes the Korn shell environment.

Description

The `$HOME/.kshrc` file is a shell script that customizes the Korn-shell environment. This `.kshrc` script often contains a list of environment variables, command aliases, and function definitions that customize the Korn-shell environment.

Each time you start a new instance of the Korn shell, the `ksh` command examines the value of the `ENV` environment variable set in the `$HOME/.profile` file. If the `ENV` environment variable contains the name of an existing, readable file, the `ksh` command runs this file as a script. By convention, this file is named `$HOME/.kshrc`. You can use another name, but you must set the `ENV` environment variable to point to it.

Note: `.kshrc` should never output (echo, print, or call any program that echos or prints) anything.

Examples

The following is a sample of a `.kshrc` script on one specific system. The contents of your `.kshrc` file can be significantly different.

```
# @(#) .kshrc 1.0
# Base Korn Shell environment
# Approach:
#      shell      initializations go in ~/.kshrc
#      user      initializations go in ~/.profile
#      host / all_user  initializations go in /etc/profile
#      hard / software  initializations go in /etc/environment

# DEBUG=y      # uncomment to report
[ "$DEBUG" ] && echo "Entering .kshrc"
set -o allexport
# options for all shells -----
# LIBPATH must be here because ksh is setuid, and LIBPATH is
# cleared when setuid programs are started, due to security hole.
LIBPATH=.:./local/lib:/lib:/usr/lib

# options for interactive shells follow-----
TTY=$(tty|cut -f3-4 -d/)
HISTFILE=$HOME/.sh_hist$(echo ${TTY} | tr -d '/')
PWD=$(pwd)
PS1='
${LOGNAME}@${HOSTNAME} on ${TTY}
[$PWD] '
# aliases
[ "$DEBUG" ] && echo "Setting aliases"
```

```

alias man="/afs/austin/local/bin/man -e less"
alias pg="pg -n -p':Page %d: ''"
alias more="pg -n -p':Page %d: ''"
alias cls="tput clear"
alias sane="stty sane"
alias rsz='eval $(resize)'

# mail check
if [ -s "$MAIL" ]      # This is at Shell startup. In
then echo"$MAILMSG"    # normal operation, the Shell checks
fi                      # periodically.

# aixterm window title
[[ "$TERM" = "aixterm" ]] && echo
"\033]0;${USER@${HOSTNAME%t1}}\007"

# functions
[ "$DEBUG" ] && echo "Setting functions"
function pid { ps -e | grep $@ | cut -d" " -f1; }
function df {
/bin/df $* | grep -v afs;
echo "\nAFS:";
/usr/afs/bin/fs listquota /afs;
}
function term {
if [ $# -eq 1 ]
then
echo $TERM
TERM=$1
export TERM
fi
echo $TERM
}

Iapi_subroutines Information

Purpose

Provides overview information about the subroutines that constitute the low-level application programming interface (LAPI).

Library

Availability Library (`liblapi_r.a`)

C Syntax

```
#include <lapi.h>

int lapi_subroutines(parm1, parm2...)
type1 parm1;
type2 parm2;
:
```

FORTRAN Syntax

```
include 'lapif.h'

API_SUBROUTINES(parm1, parm2..., ierror)
TYPE1 :: parm1;
TYPE2 :: parm2;
:
INTEGER ierror
```

Description

LAPI subroutines provide a wide variety of functions that can be used efficiently and flexibly to obtain most behaviors required from any parallel programming API.

Programming with C++

LAPI subroutines provide `extern "C"` declarations for C++ programming.

Profiling

LAPI's profiling interface includes wrappers for each LAPI function, so you can collect data about each of the LAPI calls. See the *RSCT for AIX 5L™: LAPI Programming Guide* for more information.

Querying runtime values

You can find out the size (or size range) of certain parameters by calling the `LAPI_Qenv` subroutine with the appropriate query type. For example, call `LAPI_Qenv` with the `LOC_ADDRTBL_SZ` query type to find out the size of the address table used by the `LAPI_Addr_set` subroutine:

`LAPI_Qenv(hndl, LOC_ADDRTBL_SZ, ret_val)`

Now, if you want to register a function address using `LAPI_Addr_set`:

`LAPI_Addr_set (hndl, addr, addr_hdl)`

The value of index `addr_hdl` must be in the range:

`1 <= addr_hdl < LOC_ADDRTBL_SZ`

When used to show the size of a parameter, a comparison of values, or a range of values, valid values for the `query` parameter of the `LAPI_Qenv` subroutine appear in **SMALL, BOLD** capital letters. For example:

NUM_TASKS

is a shorthand notation for:

LAPI_Qenv(*hdl*, *NUM_TASKS*, *ret_val*)

See **LAPI_Qenv** subroutine for a list of the *query* parameter's valid values.

Parameters

Parameter definitions are listed as follows:

INPUT

parm1 Describes *parm1*.

INPUT/OUTPUT

This section includes all LAPI counters.

parm2 Describes *parm2*.

OUTPUT

Function calls are nonblocking, so counter behavior is asynchronous with respect to the function call.

error Specifies a FORTRAN return code. This is always the last parameter.

Return Values

LAPI_SUCCESS

Indicates that the function call completed successfully.

Any other return values for the subroutine appear here.

For a complete list, see the *RSCT for AIX 5L: LAPI Programming Guide*.

For information about LAPI error messages, see *RSCT: Messages*.

Restrictions

Any specific restrictions for the subroutine appear here.

Also, see the *RSCT for AIX 5L: LAPI Programming Guide* for more information.

C Examples

Any C examples of the subroutine appear here.

Any FORTRAN examples of the subroutine appear here.

Idapid.Idif.template File

Purpose

Sets the base ID entry in LDAP for new accounts.

Description

The **/etc/security/ldap/ldapid.ldif.template** file can be used to update the base ID entries of an LDAP server. With proper value settings to the attributes of the base ID entry, new LDAP accounts created using the **mkuser** and **mkgroup** commands will have numeric ID values greater or equal to the corresponding base value.

For example, if *aixuserid* value is set to 10000, new user accounts created in LDAP will have numeric ID values greater than or equal to 10 000.

Because specifying IDs from the command line using the **mkuser** and **mkgroup** commands is not under control of the base ID entry, an administrator can create accounts of any ID value by specifying the ID from the command line.

The base ID entry contains the following four fields:

| Item | Description |
|------------------------|---|
| aixadmingroupid | Base ID for admin groups. The default value is 1. |
| aixadminuserid | Base ID for admin users. The default value is 1. |
| aixgroupid | Base ID for groups. The default value is 200. |
| aixuserid | Base ID for users. The default value is 200. |

These values can be changed by using the **ldapadd** command and **ldapmodify** command with the **/etc/security/ldap/ldapid.ldif.template** file. The content of the file:

Example

```
dn: cn=aixbaseid,<ou=system,cn=aixdata>
objectClass: aixadmin
aixadmingroupid: 10000
aixadminuserid: 10000
aixgroupid: 10000
aixuserid: 10000
```

Location

| Item | Description |
|--|---|
| /etc/security/ldap/ldapid.ldif.template | Contains the template base ID entry for LDAP servers. |

limits File

Purpose

Defines process resource limits for users.

Description

Note: Changing the limit does not affect those processes that were started by **init**. Alternatively, **ulimits** are only used by those processes that go through the login processes.

The **/etc/security/limits** file defines process resource limits for users. This file is an ASCII file that contains stanzas that specify the process resource limits for each user. These limits are set by individual attributes within a stanza.

Each stanza is identified by a user name followed by a colon, and contains attributes in the *Attribute=Value* form. Each attribute is ended by a new-line character, and each stanza is ended by an additional new-line character. If you do not define an attribute for a user, the system applies default values.

If the hard values are not explicitly defined in the **/etc/security/limits** file but the soft values are, the system substitutes the following values for the hard limits:

| Resource | Hard Value |
|------------------|------------|
| Core Size | unlimited |
| CPU Time | cpu |
| Data Size | unlimited |
| File Size | fsize |
| Memory Size | unlimited |
| Stack Size | 4194304 |
| File Descriptors | unlimited |
| Threads | unlimited |
| Processes | unlimited |

Note: Use a value of -1 to set a resource to unlimited.

If the hard values are explicitly defined but the soft values are not, the system sets the soft values equal to the hard values.

You can set the following limits on a user:

| Limit | Description |
|--------------|--|
| fsizE | Identifies the soft limit for the largest file a user's process can create or extend. |
| core | Specifies the soft limit for the largest core file a user's process can create. |
| cpu | Sets the soft limit for the largest amount of system unit time (in seconds) that a user's process can use. |
| data | Identifies the soft limit for the largest process data segment for a user's process. |
| stack | Specifies the soft limit for the largest process stack segment for a user's process. |
| rss | Sets the soft limit for the largest amount of physical memory a user's process can allocate. This limit is not enforced by the system. |
| nofiles | Sets the soft limit for the number of file descriptors a user process may have open at one time. |
| threads | Sets the soft limit for the number of threads per process. |
| nproc | Sets the soft limit for the number of processes per user. |
| core_hard | Specifies the largest core file a user's process can create. |
| cpu_hard | Sets the largest amount of system unit time (in seconds) that a user's process can use. |
| data_hard | Identifies the largest process data segment for a user's process. |
| fsize_hard | Identifies the largest file a user's process can create or extend. |
| rss_hard | Sets the largest amount of physical memory a user's process can allocate. This limit is not enforced by the system. |
| stack_hard | Specifies the largest process stack segment for a user's process. |
| nofiles_hard | Sets the hard limit for the number of file descriptors a user process may have open at one time. |
| threads_hard | Sets the hard limit for the number of threads per process. |
| nproc_hard | Sets the hard limit for the number of processes per user. |

Except for the **cpu**, **nofiles**, **threads**, and **nproc** attributes, each attribute must be a decimal integer string that represents the number of 512-byte blocks allotted to a user. This decimal integer represents a 32-bit value and can have a maximum value of 2147483647. The **cpu** and **nofiles** attributes represent the maximum number of seconds of system time that a user's process can use, and the maximum number of files a user's process can have open at one time. The **threads** attribute represents the maximum number

of threads each process can create. The **nproc** attribute represents the maximum number of processes each user can create. For an example of a **limits** stanza, see the "Examples" section .

When you create a user with the **mkuser** command, the system adds a stanza for the user to the **limits** file. Once the stanza exists, you can use the **chuser** command to change the user's limits. To display the current limits for a user, use the **lsuser** command. To remove users and their stanzas, use the **rmuser** command.

Note: Access to the user database files should be through the system commands and subroutines defined for this purpose. Access through other commands or subroutines may not be supported in future releases.

Security

Access Control: This file should grant read (r) access to the root user and members of the security group, and write (w) access only to the root user. Access for other users and groups depends upon the security policy for the system.

Auditing Events:

| Event | Information |
|----------------|-------------|
| S_LIMITS_WRITE | file name |

Examples

A typical record looks like the following example for user dhs:

```
dhs:  
  fsize = 8192  
  core = 4096  
  cpu = 3600  
  data = 1272  
  stack = 1024  
  rss = 1024  
  nofiles = 2000  
  threads = -1  
  nproc = -1
```

Files

| Item | Description |
|----------------------------------|--|
| /etc/security/limits | Specifies the path to the file. |
| /etc/group | Contains the basic group attributes. |
| /etc/security/group | Contains the extended attributes of groups. |
| /etc/passwd | Contains the basic user attributes. |
| /etc/security/passwd | Contains password information. |
| /etc/security/user | Contains the extended attributes of users. |
| /etc/security/environ | Contains the environment attributes of users. |
| /etc/security/audit/config | Contains audit-system configuration information. |
| /usr/lib/security/mkuser.default | Contains the default values for user accounts. |
| /etc/security/lastlog | Contains last login information. |

File and system security

local_domain File

Purpose

Contains the NFS local domain.

Description

The **/etc/nfs/local_domain** file contains the local NFS domain of the system. This local domain is used to determine how to translate incoming and outgoing NFS requests. The NFS local domain must be set before using NFS V4.

The NFS local domain may be set using the **chnfsdom** command.

The format of the **/etc/nfs/local_domain** is the domain name on the first line.

Files

| Item | Description |
|------------------------------|-------------------------------|
| /etc/nfs/local_domain | The local_domain file. |

login.cfg File

Purpose

Contains configuration information for login and user authentication.

Description

The **/etc/security/login.cfg** file is an ASCII file that contains stanzas of configuration information for login and user authentication. Each stanza has a name, followed by a colon (:), that defines its purpose. Attributes are in the form *Attribute=Value*. Each attribute ends with a newline character, and each stanza ends with an additional newline character. For an example of a stanza, see the "Examples" section.

There are two types of stanzas:

| Stanzas | Definition |
|---------------------------|---|
| port | Defines the login characteristics of ports. |
| user configuration | Defines programs that change user attributes. |

Port Stanzas

Port stanzas define the login characteristics of ports and are named with the full path name of the port. Each port should have its own separate stanza. Each stanza has the following attributes:

| Attribute | Definition |
|----------------------|--|
| herald | Defines the login message printed when the getty process opens the port. The default herald is the login prompt. The value is a character string. |
| herald2 | Defines the login message printed after a failed login attempt. The default herald is the login prompt. The value is a character string. |
| logindelay | Defines the delay factor (in seconds) between unsuccessful login attempts. The value is a decimal integer string. The default value is 0, indicating no delay between unsuccessful login attempts. |
| logindisable | Defines the number of unsuccessful login attempts allowed before the port is locked. The value is a decimal integer string. The default value is 0, indicating that the port cannot lock as a result of unsuccessful login attempts. |
| logininterval | Defines the time interval (in seconds) in which the specified unsuccessful login attempts must occur before the port is locked. The value is a decimal integer string. The default value is 0. |

| Attribute | Definition |
|----------------------|--|
| loginreenable | Defines the time interval (in minutes) a port is unlocked after a system lock. The value is a decimal integer string. The default value is 0, indicating that the port is not automatically unlocked. |
| logintimes | Specifies the times, days, or both, the user is allowed to access the system. The value is a comma-separated list of entries of the following form: <pre>[!] :time-time -or- [!] day[-day] [:time-time] -or- [!] date[-date] [:time-time]</pre> <p>The <i>day</i> variable must be one digit between 0 - 6 that represents one of the days of the week. A 0 (zero) indicates Sunday and a 6 indicates Saturday.</p> <p>The <i>time</i> variable is 24-hour military time (1700 is 5:00 p.m.). Leading zeroes are required. For example, you must enter 0800, not 800. The <i>time</i> variable must be four characters in length, and there must be a leading colon (:). An entry consisting of only a time specification applies to every day. The start hour of a time value must be less than the end hour.</p> <p>The <i>date</i> variable is a four digit string in the form <i>mmdd</i>. <i>mm</i> represents the calendar month, with 00 indicating January and 11 indicating December. <i>dd</i> represents the day number. For example 0001 represents January 1. <i>dd</i> may be 00 to indicate the entire month, if the entry is not a range, or indicating the first or last day of the month depending on whether it appears as part of the start or end of a range. For example, 0000 indicates the entire month of January. 0500 indicates the entire month of June. 0311-0500 indicates April 11 through the last day of June.</p> |
| pwdprompt | Entries in this list specify times that a user is allowed or denied access to the system. Entries not preceded by an exclamation point (!) allow access and are called ALLOW entries. Entries prefixed with an exclamation point (!) deny access to the system and are called DENY entries. The ! operator applies to only one entry, not the whole restriction list. It must appear at the beginning of an entry. |
| sak_enabled | Defines the message that is displayed at a password prompt. The message value is a character string. Format specifiers will not be interpreted. If the attribute is undefined, a default prompt from the message catalog will be used. |
| | Defines whether the secure attention key (SAK) is enabled for the port. The SAK key is the Ctrl-X, Ctrl-R key sequence. Possible values for the sak_enabled attribute are: |
| | true SAK processing is enabled, so the key sequence establishes a trusted path for the port. |
| | false SAK processing is not enabled, so a trusted path cannot be established. This is the default value. |
| synonym | The sak_enabled stanza can also be modified to close a potential exposure that exists when tty login devices are writable by others; for example, when the tty mode is 0622. If the sak_enabled stanza is set to True, the tty mode is set to a more restrictive 0600 at login. If the sak_enabled stanza is set to False (or absent), the tty mode is set to 0622. |
| usernameecho | Defines other path names for the terminal. This attribute revokes access to the port and is used only for trusted path processing. The path names should be device special files with the same major and minor number and should not include hard or symbolic links. The value is a list of comma-separated path names. |
| | Synonyms are not associative. For example, if you specify synonym=/dev/tty0 in the stanza for the /dev/console path name, then the /dev/tty0 path name is a synonym for the /dev/console path name. However, the /dev/console path name is not a synonym for the /dev/tty0 path name unless you specify synonym=/dev/console in the stanza for the /dev/tty0 path name. |
| minsl | Defines whether the user name is echoed on a port. Possible values for the usernameecho attribute are: |
| | true User name echo is enabled. The user name will be displayed. This is the default value. |
| | false User name echo is disabled. The user name will not be echoed at the login prompt and will be masked out of related messages that contain the user name. |
| | Defines the minimum sensitivity level (SL) assigned to this port. |
| | Restriction: This attribute is valid only for Trusted AIX. For more information about Trusted AIX, see Trusted AIX in <i>Security</i> . The valid values are defined in the /etc/security/enc/LabelEncodings file for the system. You must define the value in quotation marks (" ") if it has white spaces. The minsl value is dominated by the maxsl value for the port. |
| | To log in using this port, you must have an effective SL that dominates this value. |

| Attribute | Definition |
|--------------|--|
| maxsl | Defines the maximum sensitivity level assigned to this port. Restriction: This attribute is valid only for Trusted AIX. For more information about Trusted AIX, see Trusted AIX in <i>Security</i> . The valid values are defined in the <i>/etc/security/enc/LabelEncodings</i> file. You must define the value in quotation marks (" ") if it has white spaces. The maxsl value dominates the minsl value for the port. |
| tl | To log in using this port, you must have an effective SL that this value dominates. Defines the integrity level that is assigned to this port. Restriction: This attribute is valid only for Trusted AIX. For more information about Trusted AIX, see Trusted AIX in <i>Security</i> . The valid values are defined in the <i>/etc/security/enc/LabelEncodings</i> file. You must define the value in quotation marks (" ") if it has white spaces. |
| | If this value is NOTL , the user's integrity labels (TLs) are ignored; if this value is not NOTL , the user's effective TL must be equal to this value. |

User-Configuration Stanzas

User-configuration stanzas provide configuration information for programs that change user attributes. There is one user-configuration stanza: **usw**.

Note: Password restrictions have no effect if you are on a network using Network Information Services (NIS). See "Network Information Service (NIS) Overview for System Management" in *Networks and communication management* for a description of NIS.

The **usw** stanza defines the configuration of miscellaneous facilities. The following attributes can be included:

| Attribute | Definition |
|--------------------------|---|
| authcontroldomain | Specifies the domain that controls user authentication through the SYSTEM and registry attributes. If the authcontroldomain attribute is set, the SYSTEM and registry attributes of the users are queried from that domain. The SYSTEM and registry attributes for the local users are always queried from local files regardless of the authcontroldomain setting. The valid values are files or a stanza name that is defined in the <i>/etc/methods.cfg</i> file. The default value is files. |
| auth_type | Defines the route through which all users will be authenticated (in supported applications). The two values to which auth_type can be set are: <ul style="list-style-type: none"> PAM_AUTH Use PAM to authenticate users via the <i>/etc/pam.conf</i> file STD_AUTH Use an application's standard means of user authentication. This is the default value. |
| dist_uniqid | Defines the system configuration for resolving ID collision for creating/modifying user/group accounts among registries. The valid values to which dist_uniqid can be set are: <ul style="list-style-type: none"> never Do not check for ID collision against the nontarget registries. This is the default setting. always Check for ID collision against all other registries. If a collision is detected between the target registry and any other registry, account creation/modification fails. uniqbyname Check for ID collision against all other registries. Collision between registries is allowed only if the account to be created has the same name as the existing account. Note: ID collision detection in the target registry is always enforced regardless of the dist_uniqid attribute. |
| efssharedkeys | When this attribute is set to true, if any of the user shared keystore password is changed, at least his own keys will be loaded at the time of login or using the <i>efskeymgr</i> command. When this attribute is set to false, no keys will be loaded, if any of the user shared keystore password is changed. The valid values are true or false. The default value is false. |
| logintimeout | Defines the time (in seconds) the user is given to type the login name and the password. The value is a decimal integer string. The default is a value of 60. The login session will be timed out if there is no input for login name after the timer has expired. |

| Attribute | Definition | | | | |
|---------------------------|---|-------------|--|--------------|--|
| maxlogins | Defines the maximum number of simultaneous logins to the system. The format is a decimal integer string. The default value varies depending on the specific machine license. A value of 0 indicates no limit on simultaneous login attempts. Note: Login sessions include rlogins and telnets . These are counted against the maximum allowable number of simultaneous logins by the maxlogins attribute. | | | | |
| maxroles | Defines the maximum number of roles that each session allows. This attribute is for use with Enhanced RBAC Mode only. The valid value is an integer value between 1 and 8. The default value is 8. | | | | |
| mkhomeatlogin | Specifies whether to create a home directory at login if the home directory does not already exist. The value of this attribute is either true or false . The default value is false . | | | | |
| shells | Defines the valid shells on the system. This attribute is used by the chsh command to determine which shells a user can select. The value is a list of comma-separated full path names. The default is /usr/bin/sh, /usr/bin/bsh, /usr/bin/csh, /usr/bin/ksh, or /usr/bin/tsh . | | | | |
| pwd_algorithm | Defines the loadable password algorithm to use when you store user passwords. A valid value for this attribute is a stanza name that is defined in the /etc/security/pwdalg.cfg file. The default value is crypt , which is the legacy crypt() algorithm. | | | | |
| unix_passwd_compat | Sets the return value of the passwdexpired() function. The valid values for the unix_passwd_compat attribute follow: <table> <tr> <td>true</td> <td>When this attribute is set as true, the passwdexpired() function returns a non zero value, which is compatible with other UNIX and AIX operating systems, when the user password is set to * in the /etc/security/passwd file.</td> </tr> <tr> <td>false</td> <td>When this attribute is set to false, the passwdexpired() function returns 0, when the user password is set to * in the /etc/security/passwd file. This is default value.</td> </tr> </table> | true | When this attribute is set as true, the passwdexpired() function returns a non zero value, which is compatible with other UNIX and AIX operating systems, when the user password is set to * in the /etc/security/passwd file. | false | When this attribute is set to false, the passwdexpired() function returns 0, when the user password is set to * in the /etc/security/passwd file. This is default value. |
| true | When this attribute is set as true, the passwdexpired() function returns a non zero value, which is compatible with other UNIX and AIX operating systems, when the user password is set to * in the /etc/security/passwd file. | | | | |
| false | When this attribute is set to false, the passwdexpired() function returns 0, when the user password is set to * in the /etc/security/passwd file. This is default value. | | | | |

Security

Access Control

This command should grant read (r) and write (w) access to the root user and members of the security group.

Auditing Events

| Event | Information |
|----------------------|-------------|
| S_LOGIN_WRITE | File name |

Examples

A typical **port** stanza looks like the following:

```
/dev/tty0:
  sak_enabled = true
  herald = "login to tty0:"
```

On Trusted AIX systems, the port stanza looks like the following example:

```
default:
  logindisable = 3
  sak_enabled = false
  logintimes =
  logininterval = 0
  loginreenable = 0
  logindelay = 0
  mins1 = IMPL_L0
  maxs1 = "TS ALL"
  t1      = TS
```

Files

| Item | Description |
|----------------------------------|--|
| /etc/security/login.cfg | Specifies the path to the file. |
| /etc/group | Contains the basic attributes of groups. |
| /etc/security/group | Contains the extended attributes of groups. |
| /etc/passwd | Contains the basic attributes of users. |
| /etc/security/passwd | Contains password information. |
| /etc/security/user | Contains the extended attributes of users. |
| /etc/security/environ | Contains the environment attributes of users. |
| /etc/security/limits | Contains the process resource limits of users. |
| /etc/security/audit/config | Contains audit system configuration information. |
| /etc/security/lastlog | Contains last login information. |
| /etc/security/enc/LabelEncodings | Contains label definitions for the Trusted AIX system. |
| /etc/security/pwdalg.cfg | Contains configuration information for loadable password algorithms. |

su command

Ipac1 Information

Purpose

Provides general information about protecting the least-privilege (LP) commands resource class and its resources using access controls that are provided by the resource monitoring and control (RMC) subsystem.

Description

RMC controls access to all of its resources and resource classes through access control lists (ACLs), using two different ACL implementations. The implementation that RMC uses depends on which class is involved. The two major differences between the implementations are in: 1) the mechanisms with which ACLs are viewed and modified and 2) whether ACLs are associated with individual resources.

RMC implements access controls for its resources and resource classes in the following ways:

1. Through ACLs that are defined by resource class stanzas in the **ctrmc.acls** file.
You can view and modify these ACLs by editing the **ctrmc.acls** file. Use a stanza to define an ACL that applies to a class or to define an ACL that applies to all of the resources in a class.
RMC uses this method for all of its resources and resource classes, except for the **IBM.LPCommands** resource class and its resources.
For more information about the **ctrmc.acls** file and the ACLs it defines, see the *RSCT: Administration Guide*.
2. Through ACLs that are associated with resources and a resource class within the RMC subsystem.
You can view and modify these ACLs using LP commands. You can define an ACL that applies to a class or an ACL that applies to an individual resource of a class.
RMC uses this method for the **IBM.LPCommands** resource class and its resources.
This file provides information about ACLs that are specific to the **IBM.LPCommands** resource class and its resources.

The LP resource manager uses the **IBM.LPCommands** resource class to define LP resources. These resources represent commands or scripts that require **root** authority to run, but typically the users who

need to run these commands do not have **root** authority. By using the LP resource manager commands, users can run commands that require **root** authority. The LP resource manager commands are:

chlpcmd

Changes the read/write attribute values of an LP resource

lphistory

Lists or clears a certain number of LP commands that were previously issued during the current RMC session

lslpcmd

Lists information about the LP resources on one or more nodes in a domain

mklpcmd

Defines a new LP resource to RMC and specifies user permissions

rmlpcmd

Removes one or more LP resources from the RMC subsystem

runlpcmd

Runs an LP resource

For descriptions of these commands, see *RSCT for AIX 5L: Technical Reference*. For information about how to use these commands, see the *RSCT: Administration Guide*.

Because each LP resource can define a unique command, RMC implements ACLs for the **IBM.LPCommands** class that allow access to be controlled at the individual resource level and at the class level. RSCT provides a set of commands that you can use to list and modify the ACLs for the **IBM.LPCommands** class and its resources. The LP ACL commands are:

chlpcacl

Changes the Class ACL

chlpracl

Changes the Resource ACL

chlpriacl

Changes the Resource Initial ACL

chlprsacl

Changes the Resource Shared ACL

lslpcacl

Lists the Class ACL

lslpracl

Lists the Resource ACL

lslpriac1

Lists the Resource Initial ACL

lslprsacl

Lists the Resource Shared ACL

mklpcmd

Defines a new LP resource to RMC and specifies user permissions

For descriptions of these commands, see *RSCT for AIX 5L: Technical Reference*. For information about how to use these commands, see the *RSCT: Administration Guide*.

Basic ACL Structure

Typically, an ACL is composed of a list of ACL entries. Each ACL entry specifies an identity and a set of permissions granted to that identity. The complete list of ACL entries determines how the ACL controls access to the associated class or resource.

A resource-associated ACL can refer to another ACL instead of containing a list of ACL entries itself. When a resource-associated ACL refers to another ACL, the set of ACL entries in the referenced ACL controls access to the resource.

Types of ACLs

Four types of ACLs control access to the **IBM.LPCommands** class and its resources, as follows:

Class ACL

A *Class ACL* controls access to class operations on one node. You need to have been granted specific permissions to perform class operations, such as listing class attributes, creating class resources, and deleting class resources.

A Class ACL is composed of a list of ACL entries. The list of ACL entries controls access to class operations on the node. If the list is empty, no identity is permitted to perform class operations on the node.

When you try to perform a class operation on the **IBM.LPCommands** class on a node — creating a new resource, for example — RMC checks the Class ACL on that node to verify that you have the required permission to perform the operation. If you do not have the required permission, the operation is rejected.

One Class ACL exists on each node for the **IBM.LPCommands** class. Each node's Class ACL controls access to all **IBM.LPCommands** class operations on that node.

Resource ACL

A *Resource ACL* controls access to resource operations for one LP resource. You need to have been granted specific permissions to perform resource operations, such as listing resource attributes, modifying resource attributes, and running resource commands.

A Resource ACL can be composed of a list of ACL entries. In this case, the list of ACL entries controls access to resource operations for that resource. If the list is empty, no identity is permitted to perform resource operations for the resource.

A Resource ACL can refer to the Resource Shared ACL instead of containing a list of ACL entries itself. In this case, the list of ACL entries in the Resource Shared ACL controls access to resource operations for the resource. If the list is empty, no identity is permitted to perform resource operations for the resource.

When you try to perform a resource operation on an LP resource — running an LP command, for example — RMC first checks the Resource ACL for the selected resource to determine whether the Resource ACL contains a list of ACL entries or whether it refers to the Resource Shared ACL. If the Resource ACL has a list of ACL entries, RMC checks that list to verify that you have the required permission to perform the operation. If you do not have the required permission, the operation is rejected.

If the Resource ACL refers to the Resource Shared ACL, RMC checks the Resource Shared ACL to verify that you have the required permission to perform the operation. If you do not have the required permission, the operation is rejected.

One Resource ACL exists for each LP resource. When a Resource ACL refers to the Resource Shared ACL, the Resource Shared ACL that is being referenced is the one on the same node as the resource.

Resource Initial ACL

A *Resource Initial ACL* defines the initial contents of a Resource ACL created on a node.

Because a Resource Initial ACL is used to initialize Resource ACLs, a Resource Initial ACL can contain a list of ACL entries or a reference to the Resource Shared ACL.

When a new LP resource is created, its Resource ACL is initialized as specified by the Resource Initial ACL on the node.

One Resource Initial ACL exists on each node for the **IBM.LPCommands** class.

Resource Shared ACL

A *Resource Shared ACL* can control access to resource operations for multiple resources on one node.

A Resource Shared ACL is composed of a list of ACL entries. The list of ACL entries controls access to resource operations for all of the resources on the node that refer to the Resource Shared ACL. As with the other ACL types, the list of ACL entries can be empty.

To use this ACL, place ACL entries in it as you would in a Resource ACL. Then, modify the Resource ACLs on the same node to refer to the Resource Shared ACL. Using the Resource Shared ACL, you can use one list of ACL entries to control access to multiple resources on the same node.

One Resource Shared ACL exists on each node for the **IBM.LPCommands** class.

ACL Entries

An RMC ACL for LP commands specifies a list of ACL entries. Each ACL entry defines a user identity and that identity's user permissions. A *user identity* is an authenticated network identity. The *user permissions* specify the access that a user has to the class or to the resources.

User Identities

In an RMC ACL entry, the user identity can be in one of the following three forms:

1. **[host:]host_user_identifier**

Specifies a host user identifier. The optional **host:** keyword specifies that the user identifier can be matched against a network identifier that is provided by the host-based authentication (HBA) security mechanism. If the **host:** keyword is omitted and the entry does not take one of the other forms described, the entry is assumed to be a host user identifier. The host user identifier can be in one of the following three forms:

a. *user_name@host_identifier*

Specifies a particular authenticated user. You can specify *host_identifier* in several different formats. These formats, which are the same as when the host user identifier format is specified as a host identifier alone, are described as follows.

b. *host_identifier*

Specifies any authenticated user on the host identified. The host identifier can be:

- a fully-qualified host name.
- a short host name.
- an IP address.
- the RSCT node ID. This is the 16-digit hexadecimal number, for example: **0xaf58d41372c47686**.
- the keyword **LOCALHOST**. This keyword is a convenient shorthand notation for the RSCT node ID of the node where the ACL exists. The **LOCALHOST** keyword is stored in the ACL.
- the keyword **NODEID**. This keyword is a convenient shorthand notation for the RSCT node ID of the node where an ACL editing command is running. The **NODEID** keyword is not stored in the ACL; the node ID that the keyword represents is actually stored in the ACL..

c. **"**"**

Specifies any authenticated user on any host. The asterisk (*) must be enclosed in double quotation marks when it is specified as command input.

2. **none:mapped_user_identifier**

Specifies a mapped name, as defined in the **ctsec_map.global** file or the **ctsec_map.local** file. For information about mapped user identifiers, see the *RSCT: Administration Guide*.

3. **UNAUTHENT**

Specifies any unauthenticated user.

Some typical forms of a user identity are:

```
user@full_host_name  
user@short_host_name  
user@ip_address  
user@node_ID  
user@LOCALHOST  
full_host_name  
short_host_name  
IP_address  
node_ID  
LOCALHOST  
*
```

When you are running LP commands, the *host_identifier* parameter is often expected to be the RSCT node ID. You can use the **NODEID** keyword to represent the node ID of the node on which the command runs. To determine the node ID otherwise, enter:

```
lsrsrc IBM.Host NodeIDs
```

To determine all of the node IDs in a management domain or a peer domain, enter:

```
lsrsrc -ta IBM.Host NodeIDs NodeNameList
```

The node ID is displayed in decimal format. Use the hexadecimal equivalent for the *host_identifier*, preceded by **0x**. If the nodes are in a peer domain, enter:

```
lsrnode -i
```

The node ID is displayed in hexadecimal. To use this value in the commands, you need to precede this value with **0x**. If the **CT_CONTACT** environment variable is used to specify where the RMC session occurs, the *host_identifier* is expected to be a fully-qualified host name, a short host name, or an IP address.

User Permissions

The user permissions are expressed as a string of one or more characters, each representing a particular permission.

To compensate for the fine granularity of the permission set, RSCT provides two composite permissions. The **r** permission consists of individual permissions that allow "read" types of operations. The **w** permission consists of individual permissions that allow "write" types of operations. Most ACL entries will probably use these convenient composite permissions.

The Permission Set

The next two sections show two different views of the defined permission set. The first section describes the permission set using the composite permissions. The second section describes the permission set using the individual permissions.

Using Composite Permissions

- r Read permission.
 - To view the resource attribute values for an LP resource, you need this permission for the LP resource.
 - To view the **IBM.LPCommands** class attribute values, you need this permission for the **IBM.LPCommands** class.
 - You need this permission to list the LP ACLs.

Therefore, this permission is meaningful for any LP ACL. Read permission consists of the **q**, **l**, **e**, and **v** permissions.

- w Write permission.
 - To change the resource attribute values for an LP resource, you need this permission for the LP resource.
 - To change the class attribute values for the **IBM.LPCommands** class, you need this permission for the **IBM.LPCommands** class.
 - To create or delete LP resources, you need this permission for the **IBM.LPCommands** class.

Therefore, this permission is meaningful for any LP ACL. Write permission consists of the **d**, **s**, **c**, and **o** permissions.

- a Administrator permission.
 - To change the Resource ACL for an LP resource, you need this permission for the LP resource.
 - To change the Class ACL, the Resource Initial ACL, or the Resource Shared ACL, you need this permission for the **IBM.LPCommands** class.

Therefore, this permission is meaningful for any LP ACL.

- x Execute permission. To run an LP command that is defined in an LP resource, you need this permission for the LP resource. Therefore, this permission is meaningful for the LP Resource ACL, the Resource Initial ACL, and the Resource Shared ACL.
- 0 No permission. This permission denies you access to an LP resource or to the **IBM.LPCommands** class. Therefore, this permission is meaningful for any LP ACL.

Using Individual Permissions

- q Query permission.
 - To query the resource attribute values for an LP resource, you need this permission for the LP resource.
 - To query the class attribute values, you need this permission for the **IBM.LPCommands** class.
 - You need this permission to list the LP ACLs.

Therefore, this permission is meaningful for any LP ACL.

- l Enumerate permission. To list the LP resources, you need this permission for the **IBM.LPCommands** class. Therefore, this permission is meaningful for the Class ACL.
- e Event permission. To register, unregister, or query events, you need this permission for an LP resource or for the **IBM.LPCommands** class. Therefore, this permission is meaningful for any LP ACL.
- v Validate permission. You need this permission to validate that an LP resource handle still exists. Therefore, this permission is meaningful for the Resource ACL, the Resource Initial ACL, and the Resource Shared ACL.
- d Define and undefine permission. To create or delete LP resources, you need this permission for the **IBM.LPCommands** class. Therefore, this permission is meaningful for the Class ACL.

- c Refresh permission. To refresh the **IBM.LPCommands** class configuration, you need this permission for the **IBM.LPCommands** class. Therefore, this permission is meaningful for the Class ACL.
- s Set permission.
 - To set resource attribute values for an LP resource, you need this permission for the LP resource.
 - To set class attribute values, you need this permission for the **IBM.LPCommands** class.

Therefore, this permission is meaningful for any LP ACL.
- o Online, offline, and reset permission. Because LP resources do not support the online, offline, and reset operations, this permission has no meaning in LP ACLs.
- a Administrator permission.
 - To change the Resource ACL for an LP resource, you need this permission for the LP resource.
 - To change the Class ACL, the Resource Initial ACL, or the Resource Shared ACL, you need this permission for the **IBM.LPCommands** class.

Therefore, this permission is meaningful for any LP ACL.
- x Execute permission. To run an LP command that is defined in an LP resource, you need this permission for the LP resource. Therefore, this permission is meaningful for the LP Resource ACL, the Resource Initial ACL, and the Resource Shared ACL.
- 0 No permission. This permission denies you access to an LP resource or to the **IBM.LPCommands** class. Therefore, this permission is meaningful for any LP ACL.

Some permission characters have no meaning in certain types of ACLs. For example, the l permission has no meaning in a Resource ACL. A permission character that has no meaning in a certain type of ACL can be present in the ACL with no ill effect. For example, the l permission can be specified in an ACL entry of a Resource ACL. The presence of meaningless permissions in ACL entries is inevitable when the composite permissions are used.

In addition to the permissions that are granted explicitly by ACL entries, the **root** mapped identity always has query and administrator permission for ACL operations. If an ACL is set so that all access is denied, the **root** mapped identity can still be used to change the ACL, due to its implicit authority.

The system administrator needs to determine how ACLs should be defined for the **IBM.LPCommands** class and its resources. This depends on which operations users are required to perform.

Security

- To use the LP commands that change the Class ACL, the Resource Initial ACL, and the Resource Shared ACL, you must have query and administrator permission for the **IBM.LPCommands** class.
- To use the LP command that changes a Resource ACL for an LP resource, you must have query and administrator permission for the LP resource.
- To use the LP commands that list the Class ACL, the Resource Initial ACL, and the Resource Shared ACL, you must have query permission for the **IBM.LPCommands** class.
- To use the LP command that lists a Resource ACL for an LP resource, you must have query permission for the LP resource.

The **Security** section of each LP command description indicates which permissions are required for the command to run properly.

Examples

Some examples of how to modify the LP ACLs follow. In these examples, the commands are run on a management server for a group of nodes in a management domain. The management server is named

ms_node and the managed nodes are called **mc_node1**, **mc_node2**, and so forth. In a management domain, it is most likely that the LP resources will be defined on the management server and the LP commands themselves will be targeted to the managed nodes. In these examples, the Resource Shared ACL is not used because separate permissions are desired for the individual LP resources. These examples assume that the LP resources have not yet been defined using the **mklpcmd** command.

1. You want to define the **lpadmin** ID to be the administrator for the LP commands. This ID will have the authority to modify the LP ACLs. You also want to give this ID read and write permission to be able to create, delete, and modify the LP resources. To set this up, use the **root** mapped identity to run these commands on the management server:

```
chlpcacl lpadmin@LOCALHOST rwa
chlpracl lpadmin@LOCALHOST rwa
```

These commands define the **lpadmin** ID on the management server as having administrator, read, and write permission for the **IBM.LPCommands** class and for the Resource Initial ACL. The Resource Initial ACL is used to initialize a Resource ACL when an LP resource is created. Therefore, when an LP resource is created, the **lpadmin** ID will have administrator, read, and write permission to it.

2. The **lpadmin** ID can now create LP resources that define the LP commands that are needed. See the **mklpcmd** command for a description on how to create the LP resources. Access to the LP resources can be defined using the **mklpcmd** command or the **chlpracl** command. When the resource is created, the Resource Initial ACL is copied to the Resource ACL. To modify the Resource ACL using the **chlpracl** command so that **joe** will be able to use the **runlpcmd** command for the resource named **SysCmd1**, the **lpadmin** ID runs this command on the management server:

```
chlpracl SysCmd1 joe@LOCALHOST x
```

This gives **joe** on the management server execute permission to the **SysCmd1** resource so he can use the **runlpcmd** command.

3. In this example, only the **lpadmin** ID has permission to create, delete, and modify LP resources. Use the **chlpcacl** command to let other users create and delete LP resources. In this case, they need to have write access to the class. To be able to list the resources in the **IBM.LPCommands** class, read permission is required. Read permission on a Resource ACL allows a user to view that LP resource. Write permission on a Resource ACL allows a user to modify that LP resource. To allow **joe** to view the LP resource named **SysCmd1**, the **lpadmin** ID runs this command on the management server:

```
chlpracl SysCmd1 joe@LOCALHOST r
```

4. There are several nodes in a peer domain. There is an LP resource called **SysCmdB1** on **nodeB** for which **joe** needs execute permission. In addition, **joe** needs to have execute permission from nodes **nodeA**, **nodeB**, and **nodeD**. If you run the **chlpracl** command on **nodeB**, you can use **joe@LOCALHOST** for **nodeB**, but you need to determine the node IDs for **nodeA** and **nodeD**. To obtain the node IDs, enter:

```
lsrnode -i
```

The output will look like this:

| Name | OpState | RSCTVersion | NodeNum | NodeID |
|-------|---------|-------------|---------|------------------|
| nodeA | Online | 2.4.2.0 | 2 | 48ce221932ae0062 |
| nodeB | Online | 2.4.2.0 | 1 | 7283cb8de374d123 |
| nodeC | Online | 2.4.2.0 | 4 | b3eda8374bc839de |
| nodeD | Online | 2.4.2.0 | 5 | 374bdcbc384ed38a |
| nodeE | Online | 2.4.2.0 | 2 | ba74503cea374110 |
| nodeF | Online | 2.4.2.0 | 1 | 4859dfbd44023e13 |
| nodeG | Online | 2.4.2.0 | 4 | 68463748bcc7e773 |

Then, to give **joe** the permissions as stated above, run on **nodeB**:

```
chlpracl SysCmd1 -l joe@LOCALHOST joe@0x48ce221932ae0062 \
joe@0x374bdcbc384ed38a x
```

.maildelivery File for MH

Purpose

Specifies actions to be taken when mail is received.

Description

The **\$HOME/.maildelivery** file contains a list of actions the **slocal** command performs on received mail. The **slocal** command reads the **\$HOME/.maildelivery** file and performs the specified actions when you activate it.

Specify your own mail delivery instructions in the **\$HOME/.maildelivery** file. Each line in the **\$HOME/.maildelivery** file describes an action and the conditions under which the action should be performed. The following five parameters must be present in each line of the file. These parameters are separated by either commas or space characters:

Blank lines in the **.maildelivery** file are ignored. A # (pound sign) in the first column indicates a comment. The file is read from beginning to end, so several matches can be made with several actions. The **.maildelivery** file should be owned by the user, and the owner can be the only one with write access.

If the **\$HOME/.maildelivery** file cannot be found or does not deliver the message, the **/etc/mh/maildelivery** file is used in the same manner. If the message has still not been delivered, it is put in the user's mail drop. The default mail drop is the **/usr/mail/\$USER** file.

The MH package contains four standard programs that can be run as receive-mail hooks: the **rcvdist**, **rcvpack**, **rvstore**, and **rvtty** commands.

Parameters

| Item | Description |
|---------|---|
| Field | Specifies a header component to be searched for a pattern to match the <i>Pattern</i> parameter. Specify one of the following values for the <i>Field</i> parameter: Component Specify the header component you want to be searched; for example, From or cc . * Matches everything. addr Searches whatever field was used to deliver the message to you. default Matches only if the message has not been delivered yet. Source Specifies the out-of-band sender information. |
| Pattern | Specifies the character string to search for in the header component given by the <i>Field</i> parameter. For example, if you specified From in the <i>Field</i> parameter, the <i>Pattern</i> parameter might contain an address like <code>sarah@mephisto</code> . The <i>Pattern</i> parameter is not case-sensitive. The character string matches any combination of uppercase and lowercase characters. Specify a dummy pattern if you use an * (asterisk) or specify default in the <i>Field</i> parameter. |

| Item | Description |
|----------|---|
| Action | <p>Specifies an action to take with the message if it contains the pattern specified in the <i>Pattern</i> parameter. Specify the following values:</p> <ul style="list-style-type: none"> file or > Appends the message to the file specified with the "String" parameter. If the message can be written to the file, the action is considered successful. The Delivery-Date: header component is added to the message to indicate when the message was appended to the file. |
| | <p>pipe or </p> <p>Pipes the message as standard input to the command specified with the "String" parameter. The shell interprets the string. If the exit status from the command is 0, the action is considered successful. Prior to being given to the shell, the string is expanded with the following built-in variables:</p> <p>\$(Address) Address used to deliver the message.</p> <p>\$(Size) Size of the message in bytes.</p> <p>\$(reply-to) Either the Reply-To: or From: header component of the message.</p> <p>When a process is started with the pipe mechanism, the environment of the process is set as follows:</p> <ul style="list-style-type: none"> • User and group IDs are set to the recipient's IDs. • Working directory is the recipient's directory. • The value of the umask variable is 0077. • Process has no /dev/tty special file. • Standard input is set to the message. • Standard output and diagnostic output are set to the /dev/NUL special file. All other file descriptors are closed. The \$USER, \$HOME, and \$SHELL environmental variables are set appropriately; no other environment variables exist. <p>The formula for determining the amount of time the process is given to execute is:</p> <p>bytes in message x 60 + 300 seconds.</p> <p>After that time, the process is terminated.</p> <p>If the exit status of the program is 0, it is assumed that the action succeeded. Otherwise, the action is assumed unsuccessful.</p> <p>qpipe or ^ Acts similarly to pipe, but executes the command directly after built-in variable expansion without assistance from the shell. If the exit status from the command is 0, the action is successful.</p> |
| Result | <p>destroy Destroys the message. This action always succeeds.</p> <p>Indicates how the action should be performed. You can specify one of the following values for this parameter:</p> <ul style="list-style-type: none"> A Performs the action. If the action succeeds, the message is considered delivered. R Performs the action. Even if the action succeeds, the message is not considered delivered. ? Performs the action only if the message has not been delivered. If the action succeeds, the message is considered delivered. |
| "String" | <p>Specifies the file to which the message can be appended if you use the file value for the <i>Action</i> parameter.</p> <p>If you use the pipe or the qpipe value, the "String" parameter specifies the command to execute.</p> <p>If you use the destroy value as the <i>Action</i> parameter, the "String" parameter is not used, but you must still include a dummy "String" parameter.</p> |

Note: To be notified that you have mail, you must specify the **rcvtt** command in the **.maildelivery** file.

Examples

1. To save a message in a particular file, enter:

```
From george file A george.mail
```

This example directs the **slocal** command to search the **From** header line in messages. When the **slocal** command finds a message from **george**, it files the message in a file called **george.mail**.

2. To save a copy of a message in a file, enter:

```
addr manager > R proj_X/statlog
```

This example directs the **slocal** command to search the address fields in messages. When it finds a message for the project manager, the **slocal** command files a copy of the message in a file called `proj_X/statlog`. The original message is not considered delivered (the `R` value), so the message is still treated as mail and you will be notified as usual.

3. To be notified that you have received mail, enter:

```
* - | R "/usr/lib/mh/recvtt /home/sarah/allmail"
```

In this example, the `/home/sarah/allmail` file contains the line:

```
echo "You have mail\n"
```

The `/home/sarah/allmail` file must have execute permission. When you have mail, the words `You have mail` are displayed on your console.

4. To forward a copy of a message, enter:

```
addr manager | A "/usr/lib/mh/recvdist amy"
```

This example directs the **slocal** command to search the address fields in messages. When it finds a message to the project manager, the **slocal** command sends a copy of the message to `amy`. The original message is not affected. The action is always performed (the `A` value). The command that the **slocal** command reads to distribute the copy to another user is the **recvdist** command.

5. To save any undelivered messages, enter:

```
default - > ? mailbox
```

This example directs the **slocal** command to find all undelivered messages. The `-` (dash) is a placeholder for the *Pattern* parameter. The `>` (greater than sign) instructs the **slocal** command to file the messages it finds. The `?` (question mark) instructs the **slocal** command to respond only to undelivered messages. The name of the file to store undelivered messages is `mailbox`.

Files

| Item | Description |
|-----------------------------------|---|
| <code>\$HOME/.forward</code> | Searched by the sendmail command when mail is received, contains either the path of a machine to which to forward mail or a line to start the slocal command. |
| <code>/usr/mail/\$USER</code> | Provides the default mail drop. |
| <code>/usr/lib/mh/slocal</code> | Contains the slocal command that reads the <code>.maildelivery</code> file. |
| <code>/etc/mh/maildelivery</code> | Contains the mail delivery instructions that the slocal command reads if none are specified in the <code>\$HOME/.maildelivery</code> file. |
| <code>\$HOME/.maildelivery</code> | Specifies mail-related actions for the slocal command to perform. |

`sendmail` command

`slocal` command

/usr/lib/security/methods.cfg File

Purpose

Contains the information for loadable authentication module configuration.

Description

The **/usr/lib/security/methods.cfg** file is an ASCII file that contains stanzas with loadable authentication module information. Each stanza is identified by a module name followed by a colon (:) and contains attributes in the form *Attribute=Value*. Each attribute ends with a new-line character and each stanza ends with an additional new-line character.

The **/usr/lib/security/methods.cfg** file is a symbolic link to the **/etc/methods.cfg** file.

Note: If you are using Common Desktop Environment (CDE), you must restart the desktop login manager (**dtlogin**) for any changes to take effect. Restarting **dtlogin** will prevent CDE login failure by using the updated security mechanisms. Please read the **/usr/dt/README** file for more information.

Each stanza can have the following attributes:

| Attribute | Description |
|-----------------|---|
| domain | Specifies a free-format ASCII text string that is used by the loadable authentication module to select a data repository. This attribute is optional. |
| netgroup | Indicates netgroup enablement for this module. The following behaviors will be turned on: <ol style="list-style-type: none">1. Users defined in the /etc/security/user file as members of the module's registry (for example, having registry=LDAP and SYSTEM=LDAP) will not be able to authenticate as module users. These users will now become nis_module users and will require native NIS netgroup membership. To fully enable nis_module netgroup users, corresponding entries in /etc/security/user must have registry and SYSTEM value removed or set to compat.2. The registry value of compat is now supported. However, only nis_module users will show compat as their registry. Other users will show their absolute registry value.3. The meaning of registry=compat will be expanded to include modules supporting netgroup. For example, if the LDAP module is netgroup enabled, compat will include the following registries: files, NIS and LDAP. |

| Attribute options | Description |
|-----------------------------|--|
| | Specifies an ASCII text string containing optional values that are passed to the loadable authentication module upon initialization. The supported values for each module are described by the product documentation for that loadable authentication module. |
| | The options attribute takes the following pre-defined values: |
| auth=module | Specifies the module to be used to perform authentication functions for the current loadable authentication module |
| authonly | Indicates that the loadable authentication module only performs authentication operations. User and group information must be provided by a different module, specified by the db= option. If not by a module, then user and group information must be provided by the local files database. |
| db=module | Specifies the module to be used for providing user and group information for the current loadable authentication module |
| dbonly | Indicates that the loadable authentication module only provides user and group information and does not perform authentication functions. Authentication operations must be performed by a different load module, specified by the auth= option. If the auth= option is not specified, all authentication operations fail. |
| netgroup | Indicates netgroup enabling of this module. The following behaviors will be turned on: |
| | <ol style="list-style-type: none"> 1. Users defined in /etc/security/user as members of the module's registry (for example, having registry=LDAP and SYSTEM=LDAP) will not be able to authenticate as module users. These users will now become nis_module users and will require native NIS netgroup membership. To fully enable nis_module netgroup users, corresponding entries in /etc/security/user must have registry and SYSTEM values removed or set to compat. 2. The registry value of compat is now supported, however, only nis_module users will show compat as their registry value. Other users will show their absolute registry value. 3. The meaning of registry compat will be expanded to include modules supporting netgroup. For example, if LDAP module is netgroup-enabled, compat will include the following registries: files, NIS and LDAP. |
| noprompt | The initial password prompt for authentication operations is suppressed. The loadable authentication module would then control all password prompting. |
| rootrequiresopw | Determines whether the root user is prompted for the old password for this loadable authentication module when changing another user's password. If you want to disable the prompt of the old password, set this option to False. The default value is True. |

| Attribute options (continued) | Description |
|--|--|
| | <p>The options attribute can also use the following predefined values for the KRB5/KRB5A load modules:</p> |
| allow_expired_pwd=[yes true/no false] | <p>The possible values for the allow_expired_pwd option follow:</p> <ol style="list-style-type: none"> 1. No or false 2. Yes or true <p>By default the allow_expired_pwd option is set to no or false. The allow_expired_pwd option enables the AIX® operating system to get the password expiration information by using the Kerberos authentication interfaces. The actual status of the password expiration information is obtained either during the login or by calling the authenticate subroutine and the passwdexpired subroutine.</p> |
| is_kadmind_compat=[yes true/no false] | <p>This option is used to indicate which authentication service Kerberos authenticates against. If it is set to yes or true, it authenticates by using the Network Authentication Service (NAS). If it is set to no or false, the environment is set to use the non-AIX services.</p> |
| kadmind=[yes true/no false] | <p>The possible values for the kadmind option follow:</p> <ol style="list-style-type: none"> 1. No or false: Disables the kadmind lookups. 2. Yes or true: Enables the kadmind lookups. <p>The default value is yes. When this option is set to no, the kadmind daemon is not contacted during authentication. Therefore, users can log into the system regardless of the status of the kadmind daemon provided that the user enters the correct password when the system prompts for one. However, the AIX user administration commands, such as mkuser, chuser, or rmuser, do not work to administrate Kerberos integrated users if the daemon is not available (for example, either the daemon is down or the machine is not accessible). The default value for the kadmind parameter is yes. It means that kadmind lookups are performed during authentication. In the default case, if the daemon is not available, the authentication might take longer.</p> |
| kadmind_timeout=[timeout_value] | <p>The kadmind_timeout option is the amount of time in seconds between kadmind connection attempts after an initial timeout. The valid values are from 0 - 300.</p> |
| keep_creds=[yes/no] | <p>By default, the keep_creds option is set to no. If the keep_creds option is set to yes, every new login generates a new PAG based credential cache file.</p> |
| sync_all=[yes true/no false] | <p>This option is used to indicate where the processing of an ALL query is performed, either by the load module or by the security library. If the sync_all option is set to no or false, the load module leaves the task of computing an ALL request to the security library routines. If it is set to yes or true, the principal list is retrieved by the load module. The authentication side of the load module might declare no support for the ALL query. In such a case the security library is still capable of computing an ALL list for the authentication side. It does this by querying the authentication side for each user that it obtained from the database side. The resulting ALL list only contains the users and principals that exist on both sides. The advantage of this is if the number of users are too many, the Kerberos client or server might fail to complete this operation. However, querying one user at a time succeeds. The disadvantage of querying one user at a time is performance. There is a big performance degradation if the users are queried one user at a time by the security library.</p> |
| tgt_verify=[yes true/no false] | <p>The possible values for the tgt_verify option follow:</p> <ol style="list-style-type: none"> 1. No or false: Disables ticket-granting ticket (TGT) verification. 2. Yes or true: Enables TGT verification. <p>By default, the TGT verification is enabled. When the tgt_verify option is set to no, TGT verification is not performed and there is no need to transfer the keys of the host principal keys. This eliminates the need for the keytab file for authentication purposes when the KRB5A module is used. Other Kerberos-enabled applications might require the keytab file for host and service principals.</p> |

| Attribute | Description |
|-------------------------------------|---|
| options (<i>continued</i>) | You can only use the auth=module and db=module value strings for complex loadable authentication modules, which may require or be used with another loadable authentication module to provide new functionality. The authonly and dbonly values are invalid for complex modules. |
| program | You can use the noprompt value for any kind of module. |
| program_64 | Names the load module containing the executable code that implements the loadable authentication method. Names the load module containing the executable code that implements the loadable authentication method for 64-bit processes. |

Security

Access Control: This file should grant read (r) and write (w) access to the root user only and read (r) access to the security group and all other users.

Examples

1. To indicate that the loadable authentication module is located in the file /usr/lib/security/DCE, enter:

```
program = /usr/lib/security/DCE
```
2. To indicate that the loadable authentication module only should provide authentication functions, enter:

```
options = authonly
```
3. The following example contains configuration information for the LDAP simple loadable authentication module:

```
LDAP:
  program = /usr/lib/security/LDAP
  program_64 = /usr/lib/security/LDAP64
```

The "LDAP" stanza gives the name of the module, used by the **SYSTEM** and **registry** attributes for a user. The name does not have to be the same as the file name given for the **program** attribute.

4. The following example contains configuration information for the KERBEROS complex loadable authentication module:

KERBEROS:

```
program = /usr/lib/security/KERBEROS
program_64 = /usr/lib/security/KERBEROS64
options = authonly,db=LDAP
```

The "KERBEROS" stanza gives the name of the module as used by the **SYSTEM** and **registry** attributes for a user. This name does not have to be the same as the name of the file given for the **program** attribute. The **options** attribute indicates that the user and group information functions are to be performed by the module described by the "LDAP" stanza (in example 3).

Files

/usr/lib/security/methods.cfg

Specifies the path to the file.

/etc/passwd

Contains basic user attributes.

/etc/security/user

Contains the extended attributes of users.

/usr/dt/README

Contains **dtlogin** information.

Loadable Authentication Module Programming Interface

mhl.format File

Purpose

Controls the output format of the **mhl** command.

Description

The **/etc/mh/mhl.format** file controls the output format of the **mhl** command when the **mhl** command functions as the message listing program. The **/etc/mh/mhl.format** file is the default attributes file. The **mhl.digest**, **mhl.forward**, and **mhl.reply** files must be specified before use.

Each line of the **mhl.format** file must have one of the following forms:

| Form | Definition |
|---------------------------------|---|
| <i>;Comment</i> | Contains the comments specified by the <i>Comment</i> field that are ignored. |
| <i>:ClearText</i> | Contains text for output (<i>ClearText</i>). A line that contains a : (colon) only produces a blank output line. |
| <i>Component:[Variable,...]</i> | Defines the format of the specified <i>Component</i> . |
| <i>Variable[Variable,...]</i> | Applies the value specified by the <i>Variable</i> field only to the preceding component if the value follows that component. Lines having other formats define the global environment. |

The entire **mhl.format** file is parsed before output processing begins. Therefore, if the global setting of a variable is defined in multiple places, the last global definition for that variable describes the current global setting.

The following table lists the **mhl.format** file variables and parameters.

Table 2. File Variables for the *mhl.format* File

| Parameter | Variable | Description |
|-----------------------|----------------|--|
| Width | <i>integer</i> | Sets the screen width or component width. |
| Length | <i>integer</i> | Sets the screen length or component length. |
| OffSet | <i>integer</i> | Indents the <i>Component</i> parameter the specified number of columns. |
| OverflowText | <i>string</i> | Outputs the <i>String</i> parameter at the beginning of each overflow line. |
| OverflowOffset | <i>integer</i> | Indents overflow lines the specified number of columns. |
| CompWidth | <i>integer</i> | Indents component text the specified number of columns after the first line of output. |
| Uppercase | <i>flag</i> | Outputs text of the <i>Component</i> parameter in all uppercase characters. |
| NoUppercase | <i>flag</i> | Outputs text of the <i>Component</i> parameter in the case entered. |
| ClearScreen | <i>flag/G</i> | Clears the screen before each page. |
| NoClearScreen | <i>flag/G</i> | Does not clear the screen before each page. |
| Bell | <i>flag/G</i> | Produces an audible indicator at the end of each page. |

Table 2. File Variables for the mhl.format File (continued)

| Parameter | Variable | Description |
|--------------|------------------------|--|
| NoBell | <i>flag/G</i> | Does not produce an audible indicator at the end of each page. |
| Component | <i>string/L</i> | Uses the <i>String</i> parameter as the name for the specified the <i>Component</i> parameter instead of the string <i>Component</i> . |
| NoComponent | <i>flag</i> | Does not output the string <i>Component</i> for the specified <i>Component</i> parameter. |
| Center | <i>flag</i> | Centers the <i>Component</i> parameter on line. This variable works for one-line components only. |
| NoCenter | <i>flag</i> | Does not center the <i>Component</i> parameter. |
| LeftAdjust | <i>flag</i> | Strips off the leading white space characters from each line of text. |
| NoLeftAdjust | <i>flag</i> | Does not strip off the leading white space characters from each line of text. |
| Compress | <i>flag</i> | Changes new-line characters in text to space characters. |
| NoCompress | <i>flag</i> | Does not change new-line characters in text to space characters. |
| FormatField | <i>string</i> | Uses <i>String</i> as the format string for the specified component. |
| AddrField | <i>flag</i> | The specified <i>Component</i> parameter contains addresses. |
| DateField | <i>flag</i> | The specified <i>Component</i> parameter contains dates. |
| Ignore | <i>unquoted string</i> | Does not output component specified by <i>String</i> . |

Variables that have integer or string values as parameters must be followed by an = (equal sign) and the integer or string value (for example, *overflowoffset=5*). String values must also be enclosed in double quotation marks (for example, *overflowtext="***"*). A parameter specified with the /G suffix has global scope. A parameter specified with the /L suffix has local scope.

Examples

The following is an example of a line that could be displayed in the **mhl.format** file:

```
width=80,length=40,clearscreen,overflowtext="***.",overflowoffset=5
```

This format line defines the screen size to be 80 columns by 40 rows, and specifies the screen should be cleared before each page (*clearscreen*). The overflow text should be flagged with the ******* string, and the overflow indentation should be 5 columns.

.mh_profile File

Purpose

Customizes the Message Handler (MH) package.

Description

Each user of the MH package is expected to have a **\$HOME/.mh_profile** file in the home directory. This file contains a set of user parameters used by some or all of the MH programs. Each line of the file has the following format:

Profile-Entry: Value

Profile Entries

This table describes the profile entry options for the **.mh_profile** file. Only **Path:** is required. Each profile entry is stored in either the **.mh_profile** file or the *UserMHDirectory/context* file.

Table 3. Profile Entry Options for the .mh_profile File

| Profile Entry and Description | Storage File | Default Value |
|--|-------------------|---------------------------------|
| Path: The path for the <i>UserMHDirectory</i> directory. The usual location is \$HOME/Mail . | mh_profile | None |
| context: The location of the MH context file. | mh_profile | <i>UserMHDirectory /context</i> |
| Current- Folder: Tracks the current open folder. | context | inbox |
| Previous- Sequence: The <i>Messages</i> or <i>Message sequences</i> parameter given to the program. For each name given, the sequence is set to 0. Each message is added to the sequence. If not present or empty, no sequences are defined. | mh_profile | None |
| Sequence- Negation: The string negating a sequence when prefixed to the name of that sequence. For example, if set to <i>not</i> , <i>not seen</i> refers to all the messages that are not a member of the sequence <i>seen</i> . | mh_profile | None |
| Unseen- Sequence: The sequences defined as messages recently incorporated by the inc command. For each name given, the sequence is set to 0. If not present, or empty, no sequences are defined. Note: The show command removes messages from this sequence after viewing. | mh_profile | None |

Table 3. Profile Entry Options for the .mh_profile File (continued)

| Profile Entry and Description | Storage File | Default Value |
|---|-------------------|----------------------|
| .mh_sequences: The file, in each folder, defining public sequences. To disable the use of public sequences, leave the value of this entry blank. | mh_profile | .mh_sequences |
| atr- SequenceFolder: Tracks the specified sequence in the specified folder. | context | None |
| Editor: The editor to be used by the comp , dist , forw , and repl commands. | mh_profile | prompter |
| Msg-Protect: Defines octal protection bits for message files. The chmod command explains the default values. | mh_profile | 0644 |
| Folder- Protect: Defines protection bits for folder directories. The chmod command explains the default values. | mh_profile | 0711 |
| Program: Sets default flags to be used when the MH program specified by the MH program field is started. For example, override the Editor: profile entry when replying to messages by entering: repl: -editor /usr/bin/ed | mh_profile | None |
| LastEditor-next: The default editor after the editor specified by the Editor: field has been used. This takes effect at the What now? field of the comp , dist , forw , and repl commands. If you enter the editor command without a parameter to the What now? field, the editor specified by the LastEditor-next: field is used. | mh_profile | None |
| Folder-Stack: The contents of the folder stack of the folder command. | context | None |
| Alternate- Mailboxes: Indicates your address to the repl and scan commands. The repl command is given the addresses to include in the reply. The scan command is informed the message originated from you. Host names should be the official host names for the mailboxes you indicate. Local nicknames for hosts are not replaced with their official site names. If a host is not given for a particular address, that address on any host is considered to be your current address. Enter an * (asterisk) at either end or both ends of the host mailbox to indicate pattern matching. Note: Addresses must be separated by a comma. | mh_profile | \$LOGNAME |
| Draft-Folder: Indicates a default draft folder for the comp , dist , forw , and repl commands. | mh_profile | None |
| digest- issue- List: Indicates to the forw command the last issue of the last volume sent for the digest <i>List</i> . | context | None |

Table 3. Profile Entry Options for the .mh_profile File (continued)

| Profile Entry and Description | Storage File | Default Value |
|---|--------------|------------------|
| digest-volume- List: Indicates to the forw command the last volume sent for the digest <i>List</i> . | context | None |
| MailDrop: Indicates to the inc command your mail drop, if different from the default. This is superseded by the \$MAILDROP environment variable. | mh_profile | /usr/mail/\$USER |
| Signature: Indicates to the send command your mail signature. This is superseded by the \$SIGNATURE environment variable. | mh_profile | None |

Profile Elements

The following profile elements are used whenever an MH program starts another program. You can use the .mh_profile file to select alternate programs.

| Profile Element | Path |
|-----------------|------------------------|
| fileproc: | /usr/bin/refile |
| incproc: | /usr/bin/inc |
| installproc: | /usr/lib/mh/install-mh |
| lproc: | /usr/bin/more |
| mailproc: | /usr/bin/mhmail |
| mhlproc: | /usr/lib/mh/mhl |
| moreproc: | /usr/bin/more |
| mshproc: | /usr/bin/msh |
| packproc: | /usr/bin/packf |
| postproc: | /usr/lib/mh/post |
| rmmproc: | None |
| rmfproc: | /usr/bin/rmf |
| sendproc: | /usr/bin/send |
| showproc: | /usr/bin/more |
| whatnowproc: | /usr/bin/whatnow |
| whomproc: | /usr/bin/whom |

Environment Variables

| Variable | Description |
|-------------|---|
| \$MH | Specifies a profile for an MH program to read. When you start an MH program, it reads the .mh_profile file by default. Use the \$MH environment variable to specify a different profile. If the file of the \$MH environment variable does not begin with a / (slash), it is presumed to start in the current directory. The / indicates the file is absolute. |
| \$MHCONTEXT | Specifies a context file that is different from the normal context file specified in the MH profile. If the value of the \$MHCONTEXT environment variable is not absolute, it is presumed to start from your MH directory. |
| \$MAILDROP | Indicates to the inc command the default mail drop. This supersedes the MailDrop: profile entry. |
| \$SIGNATURE | Specifies your mail signature to the send and post commands. This supersedes the Signature: profile entry. |
| \$HOME | Specifies your home directory to all MH programs. |
| \$TERM | Specifies your terminal type to the MH package. In particular, these environment variables tell the scan and mhl commands how to clear your terminal, and give the width and length of your terminal in columns and lines, respectively. |
| \$editalt | Specifies an alternate message. This is set by the dist and repl commands during edit sessions so you can read the distributed message or the answered message. This message is also available through a link called @ (at sign) in the current directory, if your current directory and the message folder are on the same file system. |

| Variable | Description |
|------------|--|
| \$mhdraft | Specifies the path name of the working draft. |
| \$mhfolder | Specifies the folder containing the alternate message. This is set by the dist and repl commands during edit sessions, so you can read other messages in the current folder besides the one being distributed. The \$mhfolder environment variable is also set by the show , prev , and next commands for use by the mhl command. |

Examples

The following example has the mandatory entry for the Path:field. The option -alias aliases is used when both the **send** and **ali** commands are started. The **aliases** file resides in the mail directory. The message protection is set to 600, which means that only the user has permission to read the message files. The signature is set to Dan Carpenter, and the default editor is **vi**.

```
Path:      Mail
send:     -alias aliases
ali:      -alias aliases
Msg-Protect: 600
Signature: Dan Carpenter
Editor:   /usr/bin/vi
```

Files

| Item | Description |
|--------------------------------|---|
| \$HOME/.mh_profile | Contains the user profile. |
| <i>UserMHDirectory/context</i> | Contains the user context file. |
| <i>Folder/.mh_sequences</i> | Contains the public sequences for the folder specified by the <i>Folder</i> variable. |

mibII.my File

Purpose

Provides sample input to the **mosy** command.

Description

The **/usr/samples/snmpd/mibII.my** file is a sample input file to the **mosy** command, which creates an objects definition file for use by the **snmpinfo** command. This file is part of Simple Network Management Protocol Agent Applications in Network Support Facilities. The **mosy** compiler requires its input file to contain the ASN.1 definitions as described in the Structure and Identification of Management Information (SMI) RFC 1155 and the Management Information Base (MIB) RFC 1213. The **mibII.my** file contains the ASN.1 definitions from the MIB RFC 1213 (MIB II). RFC is the abbreviation for Request for Comments.

Comments are specified by -- (two dashes). A comment can begin at any location after the comment sign and extend to the end of the line.

The **mibII.my** file begins with a definition of the SNMP subtree of the MIB, as assigned by the Internet Activities Board (IAB). This definition contains the name of the RFCs from which the ASN.1 definitions are obtained.

```

RFC1213-MIB {iso org(3) dod(6) internet(1) mgmt(2) 1 }

DEFINITIONS ::= BEGIN

IMPORTS
    mgmt, NetworkAddress, IpAddress,
    Counter, Gauge, TimeTicks
    FROM RFC1155-SMI
    OBJECT-TYPE
    from RFC-1213;

mib-2   OBJECT IDENTIFIER ::= { mgmt 1 }-- MIB-II

system      OBJECT IDENTIFIER ::= { mib-2 1 }
interfaces   OBJECT IDENTIFIER ::= { mib-2 2 }
at          OBJECT IDENTIFIER ::= { mib-2 3 }
ip          OBJECT IDENTIFIER ::= { mib-2 4 }
icmp        OBJECT IDENTIFIER ::= { mib-2 5 }
tcp          OBJECT IDENTIFIER ::= { mib-2 6 }
udp          OBJECT IDENTIFIER ::= { mib-2 7 }
egp          OBJECT IDENTIFIER ::= { mib-2 8 }
-- cmot       OBJECT IDENTIFIER ::= { mib-2 9 }
transmission OBJECT IDENTIFIER ::= { mib-2 10}
snmp        OBJECT IDENTIFIER ::= { mib-2 11}

```

The file must contain the ASN.1 definition for each MIB variable. The ASN.1 definition is presented in an **OBJECT-TYPE** macro.

Following is the format of an **OBJECT-TYPE** macro:

| | |
|----------------------------------|---------------------|
| <i>ObjectDescriptor</i> | OBJECT-TYPE |
| SYNTAX | <i>ObjectSyntax</i> |
| ACCESS | <i>AccessMode</i> |
| STATUS | <i>StatusType</i> |
| <i>DESCRIPTION</i> | <i>Description</i> |
| ::= { <i>ObjectGroup Entry</i> } | |

The following definitions describe the pieces of the macro:

| Macro | Description |
|-------------------------|---|
| <i>ObjectDescriptor</i> | Indicates the textual name assigned to the MIB variable being defined. See RFC 1155 for the definition of the <i>ObjectDescriptor</i> variable. |
| <i>ObjectSyntax</i> | Indicates the abstract syntax for the object type. It must be one of: <ul style="list-style-type: none"> • INTEGER • OCTET STRING or DisplayString • OBJECT IDENTIFIER • NULL • Network Address • Counter • Gauge • TimeTicks • Opaque |
| | See RFC 1155 for definitions of each <i>ObjectSyntax</i> variable. |
| <i>AccessMode</i> | Specifies the permissions of the object, which can be either: <ul style="list-style-type: none"> • read-only • read-write • write-only • not-accessible |
| | See RFC 1155 for definitions of each <i>AccessMode</i> variable. |

| Macro | Description |
|--------------------|--|
| <i>StatusType</i> | Specifies the status of the object, which can be either: <ul style="list-style-type: none"> • mandatory • optional • deprecated • obsolete |
| | See RFC 1155 for definitions of each <i>StatusType</i> variable. |
| <i>Description</i> | Specifies a textual description of the purpose of the MIB variable being defined. |
| <i>ObjectGroup</i> | Defines the object group for this MIB variable. The <i>ObjectGroup</i> variable identifies the subtree for the MIB variable. See RFC 1213 for information on object groups. |
| <i>Entry</i> | Defines the unique location of the MIB variable in the <i>ObjectGroup</i> variable. |

The *ObjectGroup* and *Entry* variables are used to specify the unique numerical object identifier for each MIB variable. See RFC 1155 for an explanation of the object identifier.

See RFC 1155 for further information on the **OBJECT-TYPE** macro.

This sample **mibII.my** file was created by extracting the definitions from Chapter 6, "Definitions," of RFC 1213. This file is shipped as **/usr/samples/snmpd/mibII.my**.

Examples

The following example of an **OBJECT-TYPE** macro describes the **sysDescr** managed object:

```

sysDescr          OBJECT-TYPE
  SYNTAX           DisplayString (SIZE (0..255))
  ACCESS           read-only
  STATUS           mandatory
  DESCRIPTION      A textual description of the entity.
                    This value should include the full name and
                    version identification of system's hardware
                    type, software operating-system, and networking
                    software. It is mandatory that this only
                    contain printable ASCII characters.

  ::= { system 1 }

```

Files

| Item | Description |
|------------------------------------|--|
| /usr/samples/snmpd/mibII.my | Specifies the path of the mibII.my file. |
| /usr/samples/snmpd/smi.my | Defines the ASN.1 definitions by which the SMI is defined in RFC 1155. |
| /etc/mib.defs | Defines the Management Information Base (MIB) variables the snmpd agent should recognize and handle. This file is in the format which the snmpinfo command requires. |

Management Information Base (MIB)

Terminology Related to Management Information Base (MIB) Variables

mkuser.default File

Purpose

Contains the default attributes for new users.

Description

The **/usr/lib/security/mkuser.default** file contains the default attributes for new users. This file is an ASCII file that contains user stanzas. These stanzas have attribute default values for users created by the **mkuser** command. Each attribute has the *Attribute=Value* form. If an attribute has a value of **\$USER**, the **mkuser** command substitutes the name of the user. The end of each attribute pair and stanza is marked by a new-line character.

There are two stanzas, **user** and **admin**, that can contain all defined attributes except the **id** and **admin** attributes. The **mkuser** command generates a unique **id** attribute. The **admin** attribute depends on whether the **-a** flag is used with the **mkuser** command.

For a list of the possible user attributes, see the **chuser** command.

Security

Access Control: If read (r) access is not granted to all users, members of the security group should be given read (r) access. This command should grant write (w) access only to the root user.

Examples

A typical user stanza looks like the following:

```
user:  
  pgroup = staff  
  groups = staff  
  shell = /usr/bin/ksh  
  home = /home/$USER  
  auth1 = SYSTEM
```

User Accounts

mtstailor File for MH

Purpose

Tailors the Message Handler (MH) environment to the local environment.

Description

The entries located in the **/etc/mh/mtstailor** file specify how MH commands work. The following list describes the file entries and their default values. All of the file entries are optional.

| Entry | Description |
|---------------|--|
| localname: | Specifies the host name of the local system. If this entry is not defined, MH queries the system for the default value. |
| systemname: | Specifies the host name of the local system in the UUCP domain. If this entry is not defined, MH queries the system for the default value. |
| mmdfldir: | Specifies the location of mail drops. If this entry is present and empty, mail drops are located in the user's \$HOME directory. If this entry does not exist, mail drops are located in the /usr/mail directory. |
| mmdflfil: | Specifies the name of the file used as the mail drop. If this entry is not defined, the default file name is the same as the user name. |
| mmdelim1: | Specifies the beginning-of-message delimiter for mail drops. The default value is four Ctrl + A key sequences followed by a new-line character (. 001. 001. 001. 001. 012). A Ctrl + A key sequence is a nonprintable character not displayed on the screen. |
| mmdelim2: | Specifies the end-of-message delimiter for mail drops. The default value is four Ctrl + A key sequences followed by a new-line character (. 001. 001. 001. 001. 012). A Ctrl + A key sequence is a nonprintable character not displayed on the screen. |
| mmailid: | Specifies whether support for the MMailID variable in the /etc/passwd file is enabled. If the mmailid: entry is set to a nonzero value, support is enabled. The pw_gecos: field in the /etc/passwd file has the following form: My Full Name <i>MailID</i> When support for the MMailID variable is enabled, the internal MH routines that deal with user and full names return the MailID variable and the My Full Name , respectively. The default value is 0. |
| lockstyle: | Specifies the locking discipline. A value of 0 (zero) uses the lockf system call to perform locks. A value of 1 creates lock names by appending .lock to the name of the file being locked. The default is 0 (zero). |
| lockldir: | Specifies the directory for locked files. The default value is the /etc/locks file. |
| sendmail: | Specifies the path name of the sendmail command. The default value is the /usr/lib/sendmail file. |
| maildelivery: | Specifies the path name of the file containing the system default mail delivery instructions. The default value is the /etc/mh/maildelivery file. |
| everyone: | Specifies the users to receive messages addressed to everyone. All users having UIDs greater than the specified number (not inclusive) receive messages addressed to everyone. The default value is 200. |

Files

| Item | Description |

sendmail command

mROUTED.CONF File

Purpose

Default configuration information for the multicast routing daemon **mROUTED**.

Description

The **/etc/mROUTED.CONF** configuration file contains entries that provide configuration information used by **mROUTED**. You can specify any combination of these entries in this file.

The file format is free-form; white space and newline characters are not significant. The **phyint**, **tunnel**, and **name** entries can be specified more than once. The **boundary** and **altnet** values can be specified as many times as necessary.

The following entries and their options can be used in the **mROUTED.CONF** file:

phyint *local_addr* [**disable**] [**metric** *m*] [**threshold** *t*] [**rate_limit** *b*] [**boundary** *boundary_name* | *scoped_addr/mask_len*] [**altnet** *network/mask_len*]

The **phyint** entry can be used to disable multicast routing on the physical interface identified by the local IP address *local_addr*, or to associate a non-default metric or threshold with the specified physical interface. The local IP address can be replaced by the interface name (for example, *le0*). If a physical interface is attached to multiple IP subnets, describe each additional subnet with the **altnet** option. **Phyint** entries must precede **tunnel** entries.

The options for the **phyint** entry and the actions they generate are as follows:

local_addr

Specifies the local address, using either an IP address or an interface name, such as *en0*.

disable

Disables multicast routing on the physical interface identified by *local_addr*.

metric *m*

Specifies the "cost" associated with sending a datagram on the given interface or tunnel. This option can be used to influence the choice of routes. The default value of *m* is **1**.

Metrics should be kept as small as possible, because **mrouted** cannot route along paths with a sum of metrics greater than 31.

threshold *t*

Specifies the minimum IP time-to-live (TTL) required for a multicast datagram to be forwarded to the given interface or tunnel. This option controls the scope of multicast datagrams. (The TTL of forwarded packets is compared only to the threshold, it is not decremented by the threshold.) The default value of *t* is **1**. In general, all **mrouted** daemons connected to a particular subnet or tunnel should use the same metric and threshold for that subnet or tunnel.

rate_limit *b*

Specifies a bandwidth in Kilobits/second, which is allocated to multicast traffic. The default value of *b* is **500** Kbps on tunnels, and **0** (unlimited) on physical interfaces.

boundary *boundary_name* | *scoped_addr/mask_len*

Configures an interface as an administrative boundary for the specified scoped address. Packets belonging to this address are not forwarded on a scoped interface. The **boundary** option accepts either a boundary name or a scoped address and mask length. The *boundary_name* is the name assigned to a boundary with the **name** entry. The *scoped_addr* value is a multicast address. The *mask_len* value is the length of the network mask.

altnet *network/mask_len*

Specifies an additional subnet (*network*) attached to the physical interface described in the **phyint** entry. *mask_len* is the length of the network mask.

tunnel *local_addr* *remote_addr* [**metric** *m*] [**threshold** *t*] [**rate_limit** *b*] [**boundary** {*boundary_name* | *scoped_addr/mask_len*}] [**altnet** *network/mask_len*]

The **tunnel** entry can be used to establish a tunnel link between the local IP address (*local_addr*) and the remote IP address (*remote_addr*), and to associate a non-default metric or threshold with that tunnel. The local IP address can be replaced by the interface name (for example, *le0*). The remote IP address can be replaced by a host name, if and only if the host name has a single IP address associated with it. The tunnel must be set up in the **mrouted.conf** files of both routers before it can be used. The **phyint** entry can be used to disable multicast routing on the physical address interface identified by the local IP address *local_addr* , or to associate a non-default metric or threshold with the specified physical interface. The local IP address can be replaced by the interface name (for example, *le0*). If a physical interface is attached to multiple IP subnets, describe each additional subnet with the **altnet** option. **Phyint** entries must precede **tunnel** entries.

For a description of the options used with the **tunnel** entry, see the preceding option descriptions in the **phyint** entry.

cache_lifetime ct

The **cache_lifetime** entry determines the amount of time that a cached multicast route stays in the kernel before timing out. The value of *ct* is in seconds, and should lie between 300 (five minutes) and 86400 (one day). The default value is 300 seconds .

pruning state

The **pruning** entry enables **mROUTED** to act as a non-pruning router. The value of *state* can be either **on** or **off** . You should configure your router as a non-pruning router for test purposes only. The default mode is **on** , which enables pruning.

name boundary_name scoped_addr/mask-len

The **name** entry lets you assign names to boundaries to make it easier to configure. The **boundary** option on the **phyint** and **tunnel** entries accepts either a boundary name or a scoped address. The *boundary_name* is the name you want to give to the boundary. The *scoped_addr* value is a multicast address. The *mask_len* value is the length of the network mask.

Example

This example shows a configuration for a multicast router at a large school.

```
#  
# mrouted.conf  
#  
# Name our boundaries to make it easier  
name LOCAL 239.255.0.0/16 name EE 239.254.0.0/16  
#  
# le1 is our gateway to compsci, don't forward our  
# local groups to them  
phyint le1 boundary LOCAL  
#  
# le2 is our interface on the classroom network,  
# it has four different length subnets on it.  
# Note that you can use either an IP address or an  
# interface name  
phyint 172.16.12.38 boundary EE altnet 172.16.15.0/26  
    altnet 172.16.15.128/26 altnet 172.16.48.0/24  
#  
# atm0 is our ATM interface, which doesn't properly  
# support multicasting  
phyint atm0 disable  
#  
# This is an internal tunnel to another EE subnet.  
# Remove the default tunnel rate limit, since this tunnel  
# is over ethernets  
tunnel 192.168.5.4 192.168.55.101 metric 1 threshold 1  
    rate_limit 0  
# This is our tunnel to the outside world.  
tunnel 192.168.5.4 10.11.12.13 metric 1 threshold 32  
    boundary LOCAL boundary EE
```

netgroup File for NIS

Purpose

Lists the groups of users on the network.

Description

The **/etc/netgroup** file defines network-wide groups. This file is used for checking permissions when doing remote mounts, remote logins, and remote shells. For remote mounts, the information in the

netgroup file is used to classify machines. For remote logins and remote shells, the file is used to classify users. Each line of the **netgroup** file defines a group and is formatted as follows:

Groupname Member1 Member2 ...

where *Member* is either another group name or consists of three entries as follows:

hostname, username, domainname

Any of these three fields can be empty, in which case it signifies a wild card. The *universal* (, ,) field defines a group to which everyone belongs.

Field names that begin with something other than a letter, digit or underscore (such as -) work in precisely the opposite fashion. For example, consider the following entries:

```
justmachines  (analytica,-,ibm)
justpeople   (-,babbage,ibm)
```

The machine *analytica* belongs to the group *justmachines* in the domain *ibm*, but no users belong to it. Similarly, the user *babbage* belongs to the group *justpeople* in the domain *ibm*, but no machines belong to it.

A gateway machine should be listed under all possible host names by which it may be recognized:

wan (gateway , ,) (gateway-ebb , ,)

The *domainname* field refers to the domain *n* in which the triple is valid, not the name containing the trusted host.

Examples

The following is an excerpt from a **netgroup** file:

```
machines  (venus, -, star)
people   (-, bob, star)
```

In this example, the machine named *venus* belongs to the group *machines* in the *star* domain. Similarly, the user *bob* belongs to the group *people* in the *star* domain.

netmasks File for NIS

Purpose

Contains network masks used to implement Internet Protocol (IP) standard subnetting.

Description

The **/etc/netmasks** file contains network masks used to implement IP standard subnetting. This file contains a line for each network that is subnetted. Each line consists of the network number, any number of spaces or tabs, and the network mask to use on that network. Network numbers and masks may be specified in the conventional IP . (dot) notation (similar to IP host addresses, but with zeroes for the host part). The following number is a line from a **netmask** file:

128.32.0.0 255.255.255.0

This number specifies that the Class B network 128.32.0.0 has 8 bits of subnet field and 8 bits of host field, in addition to the standard 16 bits in the network field. When running network information service, this file on the master is used for the **netmasks.byaddr** map.

netmon.cf File

Purpose

Provides network monitoring functions.

Description

The **netmon.cf** file is an optional configuration file that customers can put in place to augment the normally available ping targets with any hosts on the network that are not defined to be part of the cluster itself, and thus would not be picked up automatically, but are reachable from the cluster nodes, specifically from the IP addresses being monitored by topology services.

If the file exists in one of these paths on a node, every NIM on that node reads it when topology services are started and try to use its contents when exercising the network monitor library functions.

This file is not controlled by any cluster subsystems; it is not distributed to any other nodes in the cluster because it is added to one of them. It must be put on each node that needs it manually.

Files

| | |
|---|---|
| /opt/rsct/samples/hats/netmon.cf | Sample version of the netmon.cf file |

lssrc Command

netsvc.conf File

Purpose

Specifies the ordering of certain name resolution services.

Description

The **/etc/netsvc.conf** file is used to specify the ordering of name resolution for the **sendmail** command, **gethostbyname** subroutine, **gethostaddr** subroutine, and **gethostent** subroutine and alias resolution for the **sendmail** command.

Several mechanisms for resolving host names and aliases are available. The **gethostbyname**, **gethostbyaddr**, and **gethostent** subroutines use these mechanisms for resolving names. A default order exists in which the resolver subroutines try the mechanisms for resolving host names and Internet Protocol (IP) addresses.

Resolving Host Names

You can override the default order and the order given in the **/etc/irs.conf** file by creating the **/etc/netsvc.conf** configuration file and specifying the desired ordering. To specify this host ordering, create an entry in the following format:

hosts = value [, value]

Use one or more of the following values for the **hosts** keyword:

| Value | Description |
|------------------|--|
| auth | Designates the specified server as <i>authoritative</i> . A resolver does not continue searching for host names further than an authoritative server. For example, when two services are given as values for the host keyword and the first service is made authoritative, and if the resolver cannot find the host name in the authoritative service, then the resolver terminates its search. However, the auth option has no effect if the resolver is unable to contact the authoritative server; in this case, the resolver continues to search the next service given in the same entry. |
| | Indicate that the specified service is authoritative by following it by an = and then auth. Note: The auth option is only valid when used in conjunction with a service value for the host keyword. |
| bind | Uses BIND/DNS services for resolving names |
| local | Searches the local /etc/hosts file for resolving names |
| nis | Uses NIS services for resolving names. NIS must be running if you specify this option |
| nis+ | Uses NIS+ services for resolving names. NIS+ must be running if you specify this option |
| nis_ldap | Uses LDAP services for resolving names. This option works if LDAP server schema is RFC 2307 compliant. |
| bind4 | Uses BIND/DNS services for resolving only IPv4 addresses |
| bind6 | Uses BIND/DNS services for resolving only IPv6 addresses |
| local4 | Searches the local /etc/hosts file for resolving only IPv4 addresses |
| local6 | Searches the local /etc/hosts file for resolving only IPv6 addresses |
| nis4 | Uses NIS services for resolving only IPv4 addresses |
| nis6 | Uses NIS services for resolving only IPv6 addresses |
| nis_ldap4 | Uses NIS LDAP services for resolving names for IPv4 addresses |
| nis_ldap6 | Uses NIS LDAP services for resolving names for IPv6 addresses |

The environment variable **NSORDER** overrides the host settings in the **/etc/netsvc.conf** file, which in turn overrides the host settings in the **/etc/irs.conf** file.

Resolving Aliases

The **sendmail** command searches the local **/etc/aliases** file, or uses NIS if specified for resolving aliases. You can override the default by specifying how to resolve aliases in the **/etc/netsvc.conf** file. To specify alias ordering to the **sendmail** command, enter the following:

```
alias = value [, value]
```

Use one or more of the following values for the **alias** keyword:

| Value | Description |
|--------------|---|
| files | Searches the local /etc/aliases file for the alias |
| nis | Uses NIS services for resolving alias |
| nis+ | Uses NIS+ services for resolving alias |

The order is specified on one line with values separated by commas. White spaces are permitted around the commas and the equal sign. The values specified and their ordering are dependent on the network configuration.

Examples

1. To use only the **/etc/hosts** file for resolving names, enter:

```
hosts = local
```

2. If the resolver cannot find the name in the **/etc/hosts** file and you want to the resolver to use NIS, enter:

```
hosts = local , nis
```

3. To use an LDAP server for resolving names, to indicate that it is authoritative, and to also use the BIND service, enter: z`

```
host = nis_ldap = auth , bind
```

In this example, if the resolver cannot contact the LDAP server, it searches the BIND service.

4. To override the default order and use only NIS for resolving aliases by the **sendmail** command, enter:

```
aliases = nis
```

sendmail command

networks File for NFS

Purpose

Contains information about networks on the NFS Internet network.

Description

The **/etc/networks** file contains information regarding the known networks that make up the Internet network. The file has an entry for each network. Each entry consists of a single line with the following information:

- Official network name
- Network number
- Aliases

Items are separated by any number of blanks or tab characters. A # (pound sign) indicates the beginning of a comment; characters up to the end of the line are not interpreted by routines that search the file.

Note: This file is not supported by the operating system. However, if this file resides on your system, Network Information Services (NIS) software will create a map for it.

NFS Services

List of NFS files

NLSvec File

Purpose

Encodes PostScript fonts for the ISO8859-1 codeset characters that have code points of more than 127 decimal.

Description

The `/usr/lib/ps/NLSvec` file can contain optional comments, optional code sets, and optional character encodings.

If a line begins with an * (asterisk), it is treated as a comment.

If a specified codeset is used, it must precede all character encodings. If a code set is not specified, the default is ISO8859-1. A specified code set uses the following syntax:

x codeset *CodeSetName*

x Use a lowercase letter.

codeset

Use all lowercase letters.

CodeSetName

Use any valid code set name available for use with the **iconv** command.

A character encoding uses the following syntax:

CodePoint PostscriptFontPosition PostscriptCharacterName

CodePoint

Displays the decimal code point for the character.

PostScriptFontPosition

Displays the new encoding for that character within the PostScript fonts. The encoding can be octal or decimal.

PostScriptCharacterName

Displays the PostScript character name.

The PostScript assigned character encodings as well as the character names can be found in the following book:

Adobe Systems Incorporated. *PostScript Language Reference Manual, Second Edition*. Reading, MA: Addison-Wesley.

Examples

Note:

1. Following is an example of a specified codeset:
x codeset ISO8859-1
2. Following is an example of a character encoding:
161 0241 exclamdown

International Character Support

By default, the output code set for the TranScript commands is ISO8859-1. The output code set can be specified with the **NLSvec** file. For the **enscript**, **ps4014**, **ps630**, and **psplot** TranScript commands, the input codeset is determined from the current locale. The mapping of characters outside the ASCII range is determined through the **iconv** subroutine using the input and output code sets. If there is no corresponding **iconv** converter, the commands treat the input data as if it were produced in ISO8859-1. This means that ASCII data is output correctly for all locales and codesets. For multibyte locales with no **iconv** converters to ISO8859-1 each byte of a multibyte character is treated as individual characters of the ISO8859-1 form. The only exception to this is the **enscript** command, which translates characters rather than bytes in the current locale through the mapping in the **NLSvec** file.

The following table lists the characters from the IBM-850 code set, which does not map directly to the ISO8859-1 code set through the **iconv** subroutine. The following characters would be mapped to 26 (0x1A) by the **iconv** subroutine and thus be discarded on output. It is possible to define an alternative **NLSvec** file for the IBM-850 code set so that more of the characters can be output on a PostScript device. The characters marked with an * (asterisk) before the character name are normally available in a PostScript font.

| Code Point | Character Name |
|------------|--|
| 159 (0x9F) | * Florin sign, PostScript name: florin |
| 176 (0xB0) | Quarter hashed |
| 177 (0xB1) | Half hashed |
| 178 (0xB2) | Full hashed |
| 179 (0xB3) | Vertical bar |
| 180 (0xB4) | Right-side middle |
| 185 (0xB9) | Double right-side middle |
| 186 (0xBA) | Double vertical bar |
| 187 (0xBB) | Double upper-right corner bar |
| 188 (0xBC) | Double lower-right corner bar |
| 191 (0xBF) | Upper-right corner box |
| 192 (0xC0) | Lower-left corner box |
| 193 (0xC1) | Bottom-side middle |
| 194 (0xC2) | Top-side middle |
| 195 (0xC3) | Left-side middle |
| 196 (0xC4) | Center box bar |
| 197 (0xC5) | Intersection |
| 200 (0xC8) | Double lower-left corner bar |
| 201 (0xC9) | Double upper-left corner bar |
| 202 (0xCA) | Double bottom-side middle |
| 203 (0xCB) | Double top-side middle |
| 204 (0xCC) | Double left-side middle |
| 205 (0xCD) | Double center box bar |

| Code Point | Character Name |
|------------|---|
| 206 (0xCE) | Double intersection |
| 213 (0xD5) | * Small dotless i, PostScript name: dotless i |
| 217 (0xD9) | Lower-right corner box |
| 218 (0xDA) | Upper-left corner box |
| 219 (0xDB) | Bright character cell |
| 220 (0xDC) | Bright character cell lower half |
| 223 (0xDF) | Bright character cell upper half |
| 242 (0xF2) | Double underscore |
| 254 (0xFE) | Vertical solid rectangle |

Files

| Item | Description |
|---------------------------|---|
| XPSLIBDIRX | Specifies the /usr/lib/ps directory. |
| /usr/lib/ps/NLSvec | Contains Adobe TranScript character encodings for the ISO8859-1 code set. This file is the default. |
| PSVECFILE | Used as an environment variable to define an NLSvec file other than the default file. |

ps630 command

/etc/nscontrol.conf File

Purpose

Contains configuration information of some name services.

Description

The **/etc/nscontrol.conf** file is a stanza file, with each stanza name representing a database name. You can use the **lssec** command and the **chsec** commands to manage the **/etc/nscontrol.conf** file. The stanza controls the following stanza names and library subroutines:

| Stanza Name | RBAC and Domain RBAC library subroutines |
|----------------|--|
| authorizations | getauthattr, getauthattrs, putauthattr, putauthattrs |
| roles | getroleattr, getroleattrs, putroleattr, putroleattrs |
| privcmds | getcmdattr, getcmdattrs, putcmdattr, putcmdattrs |
| privdevs | getdevattr, getdevattrs, putdevattr, putdevattrs |
| privfiles | getpfileattr, getpfileattrs, putpfileattr, putpfileattrs |

The below stanzas are for EFS Library subroutines and for Remote EFS Keystore support:

- efsusrkeystore
- efsgrpkeystore
- efsadmkeystore

The below stanzas are for Trusted Execution Library subroutines and for Trusted Execution Remote Signature and Policy database support:

1. tsddat
2. tepolicies

The following stanza supports the audit configuration file:

- auditconfig

You can specify the following attributes:

| Item | Description |
|---------------------|---|
| secorder | A comma-separated list of module names that library subroutines use in searching and updating a database. The following module names are valid: files Specifies the local module, namely the database files from the <code>/etc/security</code> directory. This is the default value. For EFS Keystore <code>/var/efs/<users/groups>/<username/groupname>/keystore</code> directory. LDAP Specifies the LDAP module. You must configure the system as an LDAP client. A search operation is performed on each module in the order that is specified until a matching entry is found. A failure is returned if no match is found from all of the modules. A modification operation is performed on the first entry match. A creation operation is performed on the first module in the list only. You can override the value of the secorder attribute by calling the <code>setsecorder</code> subroutine in an application program, or by using the <code>-R module</code> option on commands that support the option. |
| databasename | Specifies the database names to consider with database operations. The databasename attribute is used for Trusted Execution Databases, such as the Trusted Signature Database and the TE policy Database. While the LDAP search operation is performed these names are used as a part of Distinguished Names (DN). |

You can specify the following attribute for EFS stanzas:

| Item | Description |
|--------------------|---|
| Searchorder | A comma-separated list of module names that library subroutines use in searching and updating a database. The following module names are valid: files Specifies the local module, namely the database files from the <code>/var/efs/<users/groups>/<username/groupname>/keystore</code> directory. LDAP Specifies the LDAP module. You must configure the system as an LDAP client. A search operation is performed on each module in the order that is specified until a matching entry is found. A failure is returned if no match is found from all of the modules. A modification operation is performed on the first entry match. A creation operation is performed on the first module in the list only. You can override the value of the searchorder attribute by using the <code>-R module</code> option on commands that support the option. |

Files

| Item | Description |
|--|---|
| <code>/etc/security/domains</code> | Contains domain definitions. |
| <code>/etc/security/domobjs</code> | Contains domain objects and their associated security settings. |
| <code>/etc/security/authorizations</code> | Contains the user-defined authorizations. |
| <code>/etc/security/roles</code> | Contains role definitions. |
| <code>/etc/security/prvcmds</code> | Contains privileged command names and their associated security settings. |
| <code>/etc/security/privdevs</code> | Contains privileged device names and their associated security settings. |
| <code>/etc/security/privfiles</code> | Contains authorization lists for privileged configuration files that the <code>trvi</code> editor can access. |
| <code>/etc/security/tsd/tsd.dat</code> | Contains trusted signature database. |
| <code>/etc/security/tsd/tepolices.dat</code> | Contains trusted execution policies for the system. |
| <code>/var/efs</code> | Contains all the EFS Keystores. |

Security

This file grants read and write access to the root user. Access for other users and groups depends on the security policy for the system.

Examples

1. An example of the authorizations stanza follows:

```
authorizations:  
    secorder = files,LDAP
```

This entry states that the search for an authorization is done in the local `/etc/security/authorizations` database first. If no matching entry is found, further search is done in the `LDAP` database.

2. An example of the TE Signature Database stanza follows:

```
tsddat:  
    secorder = LDAP,files  
    databasename = TSD_v1
```

Note: In case of `tsddat` stanza and `tepolices` stanza the `secorder files, LDAP` is not a valid use case.

3. An example of the `efsusrkeystore` stanza follows:

```
efsusrkeystore:  
    secorder = LDAP,files
```

ntp.conf File

Purpose

Controls how the Network Time Protocol (NTP) daemon `xntpd` operates and behaves.

Description

The `ntp.conf` file is a basic configuration file controlling the `xntpd` daemon.

The following options are discussed in this article:

- Configuration Options
- Configuration Authentication Options
- Configuration Access Control Options
- Configuration Monitoring Options
- Miscellaneous Configuration Options

Configuration Options

In the `ntp.conf` file, comments begin with a `#` character and extend to the end of the line. Blank lines are ignored. Options consist of an initial keyword followed by a list of arguments, which may be optional, separated by whitespace. These options may not be continued over multiple lines. Arguments may be host names, host addresses written in numeric (dotted decimal) form, integers, floating point numbers (when specifying times in seconds) and text strings.

| Option | Description |
|--|---|
| peer [<i>HostAddress</i>] [key <i>Number</i>] [version <i>Number</i>] [prefer] [minpoll <i>Number</i>] [maxpoll <i>Number</i>] | <p>Specifies that the local server operate in symmetric active mode with the remote server specified by <i>HostAddress</i>. In this mode, the local server can be synchronized to the remote server, or the remote server can be synchronized to the local server. Use this method in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time.</p> <p>The key Number specifies that all packets sent to <i>HostAddress</i> include authentication fields encrypted using the specified key number. The value of <i>KeyNumber</i> is the range of an unsigned 32 bit integer.</p> <p>The version Number specifies the version number to use for outgoing NTP packets. The values for <i>Version</i> can be 1 or 2. The default is NTP version 3 implementation.</p> <p>The prefer option marks the host as a preferred host. This host is not subject to preliminary filtering.</p> <p>The minpoll number specifies the minimum poll interval allowed by any peer of the Internet system. The minimum poll interval is calculated, in seconds, as 2 to the power of minpoll value. The default value of minpoll is 6, i.e. the corresponding poll interval is 64 seconds.</p> <p>The maxpoll number specifies the maximum poll interval allowed by any peer of the Internet system. The maximum poll interval is calculated, in seconds, as 2 to the power of maxpoll value. The default value of maxpoll is 10, therefore the corresponding poll interval is ~17 minutes.</p> <p>The allowable range for minpoll and maxpoll is 4 (16 seconds) to 14 (~4.5 hours) inclusive.</p> <p>Specifies that the local server operate in client mode with the remote server specified by <i>HostAddress</i>. In this mode, the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.</p> <p>The key Number specifies that all packets sent to <i>HostAddress</i> include authentication fields encrypted using the specified key number. The value of <i>KeyNumber</i> is the range of an unsigned 32 bit integer.</p> <p>The version Number specifies the version number to use for outgoing NTP packets. The values for <i>Version</i> can be 1 or 2. The default is NTP version 3 implementation.</p> <p>The prefer argument marks the host as a preferred host. This host is not subject to preliminary filtering.</p> <p>The minpoll number specifies the minimum poll interval allowed by any peer of the Internet system. The minimum poll interval is calculated, in seconds, as 2 to the power of minpoll value. The default value of minpoll is 6, i.e. the corresponding poll interval is 64 seconds.</p> <p>The maxpoll number specifies the maximum poll interval allowed by any peer of the Internet system. The maximum poll interval is calculated, in seconds, as 2 to the power of maxpoll value. The default value of maxpoll is 10, therefore the corresponding poll interval is ~17 minutes.</p> <p>The allowable range for minpoll and maxpoll is 4 (16 seconds) to 14 (~4.5 hours) inclusive.</p> <p>The iburst option causes xntpd to send a burst of eight packets during initial synchronization acquisition instead of the single packet that is normally sent. The packet spacing is two seconds.</p> |
| server [<i>HostAddress</i>] [key <i>Number</i>] [version <i>Number</i>] [prefer] [mode <i>Number</i>] [minpoll <i>Number</i>] [maxpoll <i>Number</i>] [iburst] | |

| Option | Description |
|---|--|
| broadcast [<i>HostAddress</i>] [key Number] [version Number] [ttl Number] | <p>Specifies that the local server operate in broadcast mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address specified by <i>HostAddress</i>. Ordinarily, this specification applies only to the local server operating as a transmitter. In this mode, <i>HostAddress</i> is usually the broadcast address on [one of] the local network[s] or a multicast address. The address assigned to NTP is 224.0.1.1; presently, this is the only number that should be used.</p> <p>The key Number specifies that all packets sent to <i>HostAddress</i> include authentication fields encrypted using the specified key number. The value of <i>Number</i> is the range of an unsigned 32 bit integer.</p> <p>The version Number specifies the version number to use for outgoing NTP packets. The values for <i>Version</i> can be 1 or 2. The default is NTP version 3 implementation.</p> <p>The ttl Number is used only with the broadcast mode. It specifies the time-to-live (TTL) to use on multicast packets. This value defaults to 127.</p> |
| broadcastclient | Specifies that the local server listen for broadcast messages on the local network in order to discover other servers on the same subnet. When the local server hears a broadcast message for the first time, it measures the nominal network delay using a brief client/server exchange with the remote server, then enters the broadcastclient mode, where it listens for and synchronizes to succeeding broadcast messages. |
| multicastclient [<i>IPAddress</i> ...] | Works like broadcastclient configuration option, but operates using IP multicasting. If you give one or more IP addresses, the server joins the respective multicast group(s). If you do not give an IP address, the IP address assumed is the one assigned to NTP (224.0.1.1). |
| driftfile <i>Filename</i> | <p>Specifies the name of the file used to record the frequency offset of the local clock oscillator. The xntpd daemon reads this file at startup, if it exists, in order to set the initial frequency offset and then updates it once per hour with the current offset computed by the daemon. If the file does not exist or you do not give this option, the initial frequency offset assumed is zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm).</p> <p>Note: The update of the file occurs by first writing the current drift value into a temporary file and then using rename??? to replace the old version. The xntpd daemon must have write permission in the directory of the drift file, and you should avoid file system links, symbolic or otherwise.</p> |
| enable auth bclient pll monitor stats [...] | <p>Enables various server options. Does not affect arguments not mentioned.</p> <p>The auth option causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier. The default for this argument is disable (off).</p> <p>The bclient option causes the server to listen for a message from a broadcast or multicast server, following which an association is automatically instantiated for that server. The default for this argument is disable (off).</p> <p>The pll option enables the server to adjust its local clock, with default enable (on). If not set, the local clock free-runs at its intrinsic time and frequency offset. This option is useful when the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.</p> <p>The monitor option enables the monitoring facility, with default enable (on).</p> <p>The stats option enables statistics facility filegen, with default enable (on).</p> <p>Disables various server options. Does not affect arguments not mentioned. The options are described under the enable subcommand.</p> <p>Specifies that xntpd always slews the time. The default value is no.</p> <p>Specifies that xntpd does not exit if no configured servers are within 1000 seconds of local system time. The default value is no. If you set the ignore_bigtimestep option to yes, this takes effect only for the first instance after reading the configuration file. For later instances of encountering time shift more than 1000 seconds, the system behaves as if the ignore_bigtimestep option is set to no.</p> <p>Specifies the maximum clock offset (in seconds) used for slewing. | tracelevel <i>Number</i> | |

Configuration Authentication Options

| Option | Description |
|---|--|
| keys <i>Filename</i> | Specifies the name of a file which contains the encryption keys and key identifiers used by the xntpd daemon when operating in authenticated mode. |
| trustedkey <i>Number</i> [<i>Number</i> ...] | Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The authentication procedures require that both the local and remote servers share the same key and key identifier for this purpose, although you can use different keys with different servers. Each <i>Number</i> is a 32 bit unsigned integer. Note: The NTP key 0 is fixed and globally known. To perform meaningful authentication, the 0 key should not be trusted. |
| requestkey <i>Number</i> | Specifies the key identifier to use with the xntpdc query/control program that diagnoses and repairs problems that affect the operation of the xntpd daemon. The operation of the xntpdc query/control program is specific to this particular implementation of the xntpd daemon and can be expected to work only with this and previous versions of the daemon. Requests from a remote xntpdc program which affect the state of the local server must be authenticated, which requires both the remote program and local server share a common key and key identifier. The value of <i>Number</i> is a 32 bit unsigned integer. If you do not include requestkey in the configuration file, or if the keys do not match, such requests are ignored. |
| controlkey <i>Number</i> | Specifies the key identifier to use with the ntpq query program, that diagnoses problems that affect the operation of the xntpd daemon. The operation of the ntpq query program and the xntpd daemon conform to those specified in RFC 1305. Requests from a remote ntpq program which affect the state of the local server must be authenticated, which requires both the remote program and local server share a common key and key identifier. The value of <i>Number</i> is a 32 bit unsigned integer. If you do not include controlkey in the configuration file, or if the keys do not match, such requests are ignored. |
| authdelay <i>Seconds</i> | Specifies the amount of time it takes to encrypt an NTP authentication field on the local computer. This value corrects transmit timestamps when using authentication on outgoing packets. The value usually lies somewhere in the range 0.0001 seconds to 0.003 seconds, though it is very dependent on the CPU speed of the host computer. |

Configuration Access Control Options

The **xntpd** daemon inserts default restriction list entries, with the parameters **ignore** and **ntpport**, for each of the local host's interface addresses into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured it does not associate parameters with the default entry (everything besides your own NTP server is unrestricted).

While this facility may be useful for keeping unwanted or broken remote time servers from affecting your own, do not consider it an alternative to the standard NTP authentication facility.

restrict *Address* [**mask** *Number* | **default**] [*Parameter* ...]

Specifies the restrictions to use on the given address. The **xntpd** daemon implements a general purpose address-and-mask based restriction list. The **xntpd** daemon sorts this list by address and by mask, and searches the list in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The **xntpd** daemon uses the source address of incoming packets for the match, doing a logical and operation with the 32 bit address and the mask associated with the restriction entry. It then compares it with the entry's address (which has also been and'ed with the mask) to look for a match. The **mask** option defaults to 255.255.255.255, meaning that *Address* is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and is always the first entry in the list. The text string **default**, with no mask option, may be used to indicate the default entry.

In the current implementation, *Parameter* always restricts access. An entry with no *Parameter* gives free access to the server. More restrictive *Parameters* will often make less restrictive ones

redundant. The *Parameters* generally restrict time service or restrict informational queries and attempts to do run time reconfiguration of the server. You can specify one or more of the following value for *Parameter*:

ignore Specifies to ignore all packets from hosts which match this entry. Does not respond to queries nor time server polls.

limited

Specifies that these hosts are subject to limitation of number of clients from the same net. Net in this context refers to the IP notion of net (class A, class B, class C, and so on). Only accepts the first **client_limit** hosts that have shown up at the server and that have been active during the last **client_limit_period** seconds. Rejects requests from other clients from the same net. Only takes into account time request packets. Private, control, and broadcast packets are not subject to client limitation and therefore do not contribute to client count. The monitoring capability of the **xntpd** daemon keeps a history of clients. When you use this option, monitoring remains active. The default value for **client_limit** is 3. The default value for **client_limit_period** is 3600 seconds.

lowpriotrap

Specifies to declare traps set by matching hosts to low-priority status. The server can maintain a limited number of traps (the current limit is 3), assigned on a first come, first served basis, and denies service to later trap requestors. This parameter modifies the assignment algorithm by allowing later requests for normal priority traps to override low-priority traps.

nomodify

Specifies to ignore all NTP mode 6 and 7 packets which attempt to modify the state of the server (run time reconfiguration). Permits queries which return information.

nopeer

Specifies to provide stateless time service to polling hosts, but not to allocate peer memory resources to these hosts.

noquery

Specifies to ignore all NTP mode 6 and 7 packets (information queries and configuration requests) from the source. Does not affect time service.

noserve

Specifies to ignore NTP packets whose mode is not 6 or 7. This denies time service, but permits queries.

notrap

Specifies to decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol intended for use by remote event-logging programs.

notrust

Specifies to treat these hosts normally in other respects, but never use them as synchronization sources.

ntpport

Specifies to match the restriction entry only if the source port in the packet is the standard NTP UDP port (123).

clientlimit Number

Sets **client_limit**. Specifies the number of clients from the same network allowed to use the server. Allows the configuration of client limitation policy.

clientperiod Seconds

Sets **client_limit_period**. Specifies the number of seconds to before considering if a client is inactive and no longer counted for client limit restriction. Allows the configuration of client limitation policy.

Configuration Monitoring Options

File generation sets manage statistical files. The information obtained by enabling statistical recording allows analysis of temporal properties of a server running the **xntpd** daemon. It is usually only useful to primary servers.

statsdir *DirectoryPath*

Specifies the full path of the directory in which to create statistical files. Allows modification of the otherwise constant **filegen** filename prefix for file generation sets used for handling statistical logs.

statistics *Type...*

Enables writing of statistical records. The following are the types of statistics supported:

loopstats

Enables recording of loop filter statistical information. Each update of the local clock outputs a line of the following format to the file generation set named **loopstats**:

```
48773 10847.650 0.0001307 17.3478 2
```

The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next three fields show time offset in seconds, frequency offset in parts-per-million and time constant of the clock-discipline algorithm at each update of the clock.

peerstats

Enables recording of peer statistical information. This includes statistical records of all peers of an NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line of the following format to the current element of a file generation set named **peerstats**:

```
48773 10847.650 127.127.4.1 9714 -0.001605  
0.00000 0.00142
```

The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next two fields show the peer address in dotted-quad notation and status, respectively. The status field is encoded in hex in the format described in Appendix A of the NTP specification RFC 1305. The final three fields show the offset, delay and dispersion, all in seconds.

clockstats

Enables recording of clock driver statistical information. Each update received from a clock driver outputs a line of the following form to the file generation set named **clockstats**:

```
49213 525.624 127.127.4.1 93 226  
00:08:29.606 D
```

The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next field shows the clock address in dotted-quad notation. The final field shows the last timecode received from the clock in decoded ASCII format, where meaningful. You can gather and display a good deal of additional information in some clock drivers.

filegen *Name* [**file** *FileName*] [**type** *TypeName*] [**flag** *flagval*] [**link**] [**nolink**] [**enable**] [**disabled**]

Configures setting of generation fileset name. Generation filesets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation filesets provide access to a set of files used to store the actual data. A file generation set is characterized by its type. At any time, at most one element of the set is being written to. Filenames of set members are built from three elements:

Prefix This is a constant filename path. It is not subject to modifications with the **filegen** option. It is defined by the server, usually specified as a compile time constant. You can,

however, configure it for individual file generation sets with other commands. For example, you can configure the prefix used with `loopstats` and `peerstats` filegens using the `statsdir` option.

file *FileName*

The string *FileName* is directly concatenated to the prefix with no intervening slash (/). You can modify this by using the **file** argument to the **filegen** option. To prevent filenames referring to parts outside the filesystem hierarchy denoted by prefix, ".." elements are not allowed in this component

Suffix This part reflects individual elements of a fileset. It is generated according to the type of a fileset.

type *TypeName*

Specifies when and how to direct data to a new element of the set. This way, information stored in elements of a fileset that are currently unused are available for administrative operations without the risk of disturbing the operation of the `xntpd` daemon. Most important, you can remove them to free space for new data produced. The following types are supported:

none Specifies that the fileset is actually a single plain file.

pid Specifies the use of one element of fileset per server running the `xntpd` daemon. This type does not perform any changes to fileset members during runtime; however, it provides an easy way of separating files belonging to different servers running the `xntpd` daemon. The set member filename is built by appending a dot (.) to concatenated prefix and strings denoted in **file Name**, and appending the decimal representation of the process id of the `xntpd` server process.

day Specifies the creation of one file generation set element per day. The term day is based on UTC. A day is the period between 00:00 and 24:00 UTC. The fileset member suffix consists of a dot (.) and a day specification in the form YYYYMMDD. where YYYY is a 4 digit year number, MM is a two digit month number, and, DD is a two digit day number. For example, all information written at January 10th, 1992 would end up in a file named PrefixFileName.19920110.

week Specifies the creation of one file generation set element per week. A week is computed as day-of-year modulo 7. The fileset member suffix consists of a dot (.), a four digit year number, the letter W, and a two digit week number. For example, all information written at January, 10th 1992 would end up in a file named PrefixFileName.1992W1.

month Specifies the creation of one file generation set element per month. The fileset member suffix consists of a dot (.), a four digit year number, and a two digit month number. For example, all information written at January, 1992 would end up in a file named PrefixFileName.199201.

year Specifies the creation of one file generation set element per year. The fileset member suffix consists of a dot (.) and a four digit year number. For example, all information written at January, 1992 would end up in a file named PrefixFileName.1992.

age Specifies the creation of one file generation set element every 24 hours of server operation. The fileset member suffix consists of a dot (.), the letter a, and an eight digit number. This number is the number of seconds of run-time of the server since the start of the corresponding 24 hour period.

enable

Enables the writing of information to a file generation set.

disabled

Disables the writing of information to a file generation set.

link Enables the access of the current element of a file generation set by a fixed name by creating a hard link from the current files set element to a file without *Suffix*. If a file with this name already exists and the number of links of this file is one, it is renamed by appending a dot (.), the letter C, and the pid of the **xntpd** server process. If the number of links is greater than one, the file is unlinked. This allows access of the current file by a constant name.

nolink

Disables access the current element of a file generation set by a fixed name.

Miscellaneous Configuration Options

| Option | Description |
|--|--|
| precision <i>Number</i> | Specifies the nominal precision of the local clock. The <i>Number</i> is an integer approximately equal to the base 2 logarithm of the local timekeeping precision in seconds. Normally, the xntpd daemon determines the precision automatically at startup, so use this option when the xntpd daemon cannot determine the precision automatically. |
| broadcastdelay <i>Seconds</i> | Specifies the default delay to use when in broadcast or multicast modes. These modes require a special calibration to determine the network delay between the local and remote servers. Normally, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to network or server access controls, for example. |
| trap <i>HostAddress</i> [port <i>Number</i>] [interface <i>Address</i>] | Configures a trap receiver at the given host address and port number for sending messages with the specified local interface address. If you do not specify the port number, the value defaults to 18447. If you do not specify the interface address, the value defaults to the source address of the local interface. Note: On a multihomed host, the interface used may vary from time to time with routing changes. |
| setvar <i>Variable</i> [default] | Normally, the trap receiver logs event messages and other information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that when the server starts, no messages are lost. Specifies to add an additional system variable. You can use these variables to distribute additional information such as the access policy. If default follows a variable of the form <i>Name=Value</i> , then the variable becomes part of the default system variables, as if you used the ntpq rv command. These additional variables serve informational purposes only; they are not related to the protocol variables. The known protocol variables always override any variables defined with setvar . There are three special variables that contain the names of all variables of the same group. The sys_var_list holds the names of all system variables, the peer_var_list holds the names of all peer variables, and the clock_var_list holds the names of the reference clock variables. |

| Option | Description |
|----------------------|---|
| logconfig Key | Controls the amount of output written to syslog or the logfile. By default all output is turned on. You can prefix all <i>KeyWords</i> with = (equal), + (plus) and - (dash). You can control four classes of messages: sys, peer, clock, and sync. Within these classes, you can control four types of messages: |
| info | Outputs informational messages that control configuration information. |
| events | Outputs event messages that control logging of events (reachability, synchronization, alarm conditions). |
| status | Outputs statistical messages that describe mainly the synchronization status. |
| all | Outputs all messages having to do with the specified class and suppresses all other events and messages of the classes not specified. |

You form the *KeyWord* by concatenating the message class with the event class. To just list the synchronization state of **xntp** and the major system events, enter:

```
logconfig =syncstatus +sysevents
```

To list all clock information and synchronization information and have all other events and messages about peers, system events and so on suppressed, enter:

```
logconfig =syncall +clockall
```

Files

| Item | Description |
|---------------|---------------------------------|
| /etc/ntp.conf | Specifies the path to the file. |

"ntp.keys File" on page 197

Related information:

xntpdc command

xntpd command

ntp.conf4 File

Purpose

Controls the operation and behaviour of the Network Time Protocol (NTP) **ntpd** daemon.

Description

The **ntp.conf** file is a basic configuration file controlling the **ntpd** daemon.

Configuration Options

There are two classes of commands, configuration commands that configure an association with a remote server, peer or reference clock, and auxiliary commands that specify environmental variables that control various related operations:

Configuration Commands

There are two classes of commands, configuration commands that configure an association with a remote server, peer or reference clock, and auxiliary commands that specify environmental variables that control various related operations:

```
server address [options ...]
peer address [options ...]
broadcast address [options ...]
multicastclient address [options ...]
```

These four commands specify the time server name or address to be used and the mode in which to operate. The address can be either a DNS name or an IP address in dotted-quad notation. Additional information on association behavior can be found in the Association Management page.

| Command | Description |
|------------------------|--|
| server | For type s and r addresses (only), this command normally mobilizes a persistent client mode association with the specified remote server or local reference clock. If the preempt flag is specified, a peerable association is mobilized instead. In client mode the client clock can synchronize to the remote server or local reference clock, but the remote server can never be synchronized to the client clock. This command should NOT be used for type b or m addresses. |
| peer | For type s addresses (only), this command mobilizes a persistent symmetric-active mode association with the specified remote peer. In this mode the local clock can be synchronized to the remote peer or the remote peer can be synchronized to the local clock. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote peer may be the better source of time. This command should NOT be used for type b , m or r addresses. |
| broadcast | For type b and m addresses (only), this command mobilizes a persistent broadcast mode association. Multiple commands can be used to specify multiple local broadcast interfaces (subnets) and/or multiple multicast groups. Note that local broadcast messages go only to the interface associated with the subnet specified, but multicast messages go to all interfaces. In broadcast mode the local server sends periodic broadcast messages to a client population at the address specified, which is usually the broadcast address on (one of) the local network(s) or a multicast address assigned to NTP. The IANA has assigned the multicast group address IPv4 224.0.1.1 and IPv6 ff05::101 (site local) exclusively to NTP, but other nonconflicting addresses can be used to contain the messages within administrative boundaries. Ordinarily, this specification applies only to the local server operating as a sender; for operation as a broadcast client, see the broadcastclient or multicastclient commands below. |
| multicastclient | For type m addresses (only), this command mobilizes a preemptable multicast client mode association for the multicast group address specified. In this mode a specific address must be supplied which matches the address used on the multicastserver command for the designated multicast servers. The NTP multicast address 224.0.1.1 assigned by the IANA should NOT be used, unless specific means are taken to avoid spraying large areas of the Internet with these messages and causing a possibly massive implosion of replies at the sender. The multicastclient command specifies that the host is to operate in client mode with the remote servers that are discovered as the result of broadcast/multicast messages. The client broadcasts a request message to the group address associated with the specified address and specifically enabled servers respond to these messages. The client selects the servers providing the best time and continues as with the server command. The remaining servers are discarded. |

Command options

| Command | Options |
|--|--|
| autokey | All packets sent to and received from the server or peer are to include authentication fields encrypted using the autokey scheme described in the Authentication Options page. This option is valid with all commands. |
| burst | When the server is reachable, send a burst of eight packets instead of the usual one. The packet spacing is normally 2 s; however, the spacing between the first and second packets can be changed with the calldelay command to allow additional time for a modem or ISDN call to complete. This option is valid with only the server command and is a recommended option with this command when the maxpoll option is 11 or greater. |
| iburst | When the server is unreachable, send a burst of eight packets instead of the usual one. The packet spacing is normally 2 s; however, the spacing between the first and second packets can be changed with the calldelay command to allow additional time for a modem or ISDN call to complete. This option is valid with only the server command and is a recommended option with this command. |
| key key | All packets sent to and received from the server or peer are to include authentication fields encrypted using the specified key identifier with values from 1 to 65534, inclusive. The default is to include no encryption field. This option is valid with all commands. |
| minpoll minpollmaxpoll maxpoll | These options specify the minimum and maximum poll intervals for NTP messages, in seconds as a power of two. The maximum poll interval defaults to 10 (1,024 s), but can be increased by the maxpoll option to an upper limit of 17 (36.4 h). The minimum poll interval defaults to 6 (64 s), but can be decreased by the minpoll option to a lower limit of 4 (16s). These option are valid only with the server and peer commands. |
| noselect | Marks the server as unused, except for display purposes. The server is discarded by the selection algorithm. This option is valid only with the server and peer commands. |

| Command | Options |
|------------------------|--|
| preempt | Specifies the association as preemptable rather than the default persistent. This option is valid only with the server command. |
| prefer | Marks the server as preferred. All other things being equal, this host will be chosen for synchronization among a set of correctly operating hosts. See the Mitigation Rules and the prefer Keyword page for further information. This option is valid only with the server and peer commands. |
| true | Force the association to assume truechimer status; that is, always survive the selection and clustering algorithms. This option can be used with any association, but is most useful for reference clocks with large jitter on the serial port and precision pulse-per-second (PPS) signals. Note: This option defeats the algorithms designed to cast out falsestickers and can allow these sources to set the system clock. This option is valid only with the server and peer commands. |
| ttl ttl | This option is used only with broadcast server and manycast client modes. It specifies the time-to-live ttl to use on broadcast server and multicast server and the maximum ttl for the expanding ring search with manycast client packets. Selection of the proper value, which defaults to 127, is something of a black art and should be coordinated with the network administrator. |
| version version | Specifies the version number to be used for outgoing NTP packets. Versions 1-4 are the choices, with version 4 the default. This option is valid only with the server, peer and broadcast commands. |

Auxiliary Commands

| Command | Description |
|--------------------------------------|---|
| broadcastclient [novolley] | This command enables reception of broadcast server messages to any local interface (type b) address. Ordinarily, upon receiving a message for the first time, the broadcast client measures the nominal server propagation delay using a brief client/server exchange with the server, after which it continues in listen-only mode. If the novolley keyword is present, the exchange is not used and the value specified in the broadcastdelay command is used or, if the broadcastdelay command is not used, the default 4.0 ms. Note: In order to avoid accidental or malicious disruption in this mode, both the server and client should operate using symmetric key or public key authentication as described in the Authentication Options page. Note that the novolley keyword is incompatible with public key authentication. |
| multicastclient address [...] | This command enables reception of manycast client messages to the multicast group address(es) (type m) specified. At least one address is required. The NTP multicast address 224.0.1.1 assigned by the IANA should NOT be used, unless specific means are taken to limit the span of the reply and avoid a possibly massive implosion at the original sender. Note: In order to avoid accidental or malicious disruption in this mode, both the server and client should operate using symmetric key or public key authentication as described in the Authentication Options page. |
| multicastserver address [...] | This command enables reception of multicast server messages to the multicast group address(es) (type m) specified. Upon receiving a message for the first time, the multicast client measures the nominal server propagation delay using a brief client/server exchange with the server, then enters the broadcast client mode, in which it synchronizes to succeeding multicast messages. Note: In order to avoid accidental or malicious disruption in this mode, both the server and client should operate using symmetric key or public key authentication. Note that, |

Configuration access control options

The ntpd daemon implements a general purpose address/mask based restriction list. The list contains address/match entries sorted first by increasing address values and then by increasing mask values. A match occurs when the bitwise AND of the mask and the packet source address is equal to the bitwise AND of the mask and address in the list. The list is searched in order with the last match found defining the restriction flags associated with the entry.

While this facility may be useful for keeping unwanted or broken or malicious clients from congesting innocent servers, it should not be considered an alternative to the NTP authentication facilities. Source address based restrictions are easily circumvented by a determined cracker.

Clients can be denied service because they are explicitly included in the restrict list created by the restrict command or implicitly as the result of cryptographic or rate limit violations. Cryptographic violations include certificate or identity verification failure; rate limit violations generally result from defective NTP implementations that send packets at abusive rates. Some violations cause denied service only for the

offending packet, others cause denied service for a timed period and others cause the denied service for an indefinite period. When a client or network is denied access for an indefinite period, the only way at present to remove the restrictions is by restarting the server.

| Command | Description |
|--|---|
| discard [average avg][minimum min] [monitor prob] | Set the parameters of the limited facility which protects the server from client abuse. The average subcommand specifies the minimum average packet spacing, while the minimum subcommand specifies the minimum packet spacing. Packets that violate these minima are discarded and a kiss-o'-death packet returned if enabled. The default minimum average and minimum are 5 and 2, respectively. The monitor subcommand specifies the probability of discard for packets that overflow the rate-control window. |
| restrict address [mask mask] [flag][...] | The address argument expressed in dotted-quad form is the address of a host or network. Alternatively, the address argument can be a valid host DNS name. The mask argument expressed in dotted-quad form defaults to 255.255.255.255, meaning that the address is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and is always the first entry in the list. Note that text string default, with no mask option, may be used to indicate the default entry. |

In the current implementation, flag always restricts access, therefore, an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags will often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run-time reconfiguration of the server. One or more of the following flags may be specified:

| Flags | Description |
|-------------------|--|
| ignore | Deny packets of all kinds, including ntpq and ntpdc queries. |
| kod | If this flag is set when an access violation occurs, a kiss-o'-death (KoD) packet is sent. KoD packets are rate limited to no more than one per second. If another KoD packet occurs within one second after the last one, the packet is dropped. |
| limited | Deny service if the packet spacing violates the lower limits specified in the discard command. A history of clients is kept using the monitoring capability of the ntpd command. Monitoring is always active as long as there is a restriction entry with the limited flag. |
| lowpritrap | Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited (the current limit is 3). Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps. |
| nomodify | Deny ntpq and ntpdc queries which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted. |
| noquery | Deny ntpq and ntpdc queries. Time service is not affected. |
| nopeer | Deny packets which would result in mobilizing a new association. This includes broadcast, symmetric-active and manycast client packets when a configured association does not exist. |
| noserve | Deny all packets except ntpq and ntpdc queries. |
| notrap | Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the ntpdq control message protocol which is intended for use by remote event logging programs. |
| notrust | Deny packets unless the packet is cryptographically authenticated. |
| ntpport | This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard NTP UDP port (123). Both ntpport and non- ntpport may be specified. The ntpport is considered more specific and is sorted later in the list. |
| version | Deny packets that do not match the current NTP version. |

Default restriction list entries with the flags **ignore**, **interface**, **ntpport**, for each of the local host's interface addresses are inserted into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured; no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

Configuration authentication options

Authentication support allows the NTP client to verify that the server is in fact known and trusted and not an intruder intending accidentally or on purpose to masquerade as that server. The NTPv3 specification RFC-1305 defines a scheme which provides cryptographic authentication of received NTP packets. Originally, this was done using the Data Encryption Standard (DES) algorithm operating in Cipher Block Chaining (CBC) mode, commonly called DES-CBC. Subsequently, this was replaced by the RSA Message Digest 5 (MD5) algorithm using a private key, commonly called keyed-MD5. Either algorithm computes a message digest, or one-way hash, which can be used to verify the server has the correct private key and key identifier.

NTPv4 retains the NTPv3 scheme, properly described as symmetric key cryptography, and, in addition, provides a new Autokey scheme based on public key cryptography. Public key cryptography is generally considered more secure than symmetric key cryptography, since the security is based on a private value which is generated by each host and never revealed. With the exception of the group key described later, all key distribution and management functions involve only public values, which considerably simplifies key distribution and storage. Public key management is based on X.509 certificates, which can be provided by commercial services or produced by utility programs in the OpenSSL software library or the NTPv4 distribution.

| Commands | Description |
|--|--|
| autokey [logsec] | Specifies the interval between regenerations of the session key list used with the Autokey protocol. Note that the size of the key list for each association depends on this interval and the current poll interval. The default value is 12 (4096 s or about 1.1 hours). For poll intervals above the specified interval, a session key list with a single entry will be regenerated for every message sent. |
| controlkey key | Specifies the key identifier to use with the ntpq utility, which uses the standard protocol defined in RFC-1305. The key argument is the key identifier for a trusted key, where the value can be in the range 1 to 65,534, inclusive. |
| crypto [cert file] [leap file] [randfile file] [host file] [sign file] [ident scheme] [iffpar file] [gqpar file] [mvpar file] [pw password] | This command requires the OpenSSL library. It activates public key cryptography, selects the message digest and signature encryption scheme and loads the required private and public values described above. If one or more files are left unspecified, the default names are used as described above. Unless the complete path and name of the file are specified, the location of a file is relative to the keys directory specified in the keysdir command or default /usr/local/etc. |

Following are the sub commands.

| Subcommands | Description |
|----------------------|--|
| <i>cert file</i> | Specifies the location of the required host public certificate file. This overrides the link ntpkey_cert_hostname in the keys directory. |
| <i>gqpar file</i> | Specifies the location of the client GQ parameters file. This overrides the link ntpkey_gq_hostname in the keys directory. |
| <i>host file</i> | Specifies the location of the required host key file. This overrides the link ntpkey_key_hostname in the keys directory. |
| <i>ident scheme</i> | Requests the server identity scheme, which can be IFF, GQ or MV. This is used when the host will not be a server for a dependent client. |
| <i>iffpar file</i> | Specifies the location of the optional IFF parameters file. This overrides the link ntpkey_iff_hostname in the keys directory. |
| <i>leap file</i> | Specifies the location of the client leapsecond file. This overrides the link ntpkey_leap in the keys directory. |
| <i>mv</i> | Requests the MV server identity scheme. |
| <i>mvpar file</i> | Specifies the location of the client MV parameters file. This overrides the link ntpkey_mv_hostname in the keys directory. |
| <i>pw password</i> | Specifies the password to decrypt files containing private keys and identity parameters. This is required only if these files have been encrypted. |
| <i>randfile file</i> | Specifies the location of the random seed file used by the OpenSSL library. The defaults are described in the main text above. |
| <i>sign file</i> | Specifies the location of the optional sign key file. This overrides the link ntpkey_sign_hostname in the keys directory. If this file is not found, the host key is also the sign key. |

| Subcommands | Description |
|-----------------------------------|--|
| <code>keys keyfile</code> | Specifies the complete path and location of the MD5 key file containing the keys and key identifiers used by ntpd , ntpq and ntpdc when operating with symmetric key cryptography. This is the same operation as the -k command line option. |
| <code>keysdir path</code> | This command specifies the default directory path for cryptographic keys, parameters and certificates. The default is <code>/usr/local/etc/</code> . |
| <code>requestkey key</code> | Specifies the key identifier to use with the ntpdc utility program, which uses a proprietary protocol specific to this implementation of ntpd . The key argument is a key identifier for the trusted key, where the value can be in the range 1 to 65,534, inclusive. |
| <code>revoke [logsec]</code> | Specifies the interval between re-randomization of certain cryptographic values used by the Autokey scheme, as a power of 2 in seconds. These values need to be updated frequently in order to deflect brute-force attacks on the algorithms of the scheme; however, updating some values is a relatively expensive operation. The default interval is 16 (65,536 s or about 18 hours). For poll intervals above the specified interval, the values will be updated for every message sent |
| <code>trustedkey key [...]</code> | Specifies the key identifiers which are trusted for the purposes of authenticating peers with symmetric key cryptography, as well as keys used by the ntpq and ntpdc programs. The authentication procedures require that both the local and remote servers share the same key and key identifier for this purpose, although different keys can be used with different servers. The key arguments are 32-bit unsigned integers with values from 1 to 65,534. |

Configuration monitoring options

ntpd includes a comprehensive monitoring facility suitable for continuous, long term recording of server and client timekeeping performance. See the statistics command below for a listing and example of each type of statistics currently supported. Statistic files are managed using file generation sets and scripts in the `./scripts` directory of this distribution. Using these facilities and UNIX cron jobs, the data can be automatically summarized and archived for retrospective analysis.

| Commands | Description |
|------------------------------------|--|
| <code>statistics name [...]</code> | Enables writing of statistics records. Currently, six kinds of name statistics are supported. |
| <code>clockstats</code> | Enables recording of clock driver statistics information. Each update received from a clock driver appends a line of the following form to the file generation set named <code>clockstats</code> : 49213 525.624 127.127.4.1 93 226 00:08:29.606 D The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next field shows the clock address in dotted-quad notation. The final field shows the last timecode received from the clock in decoded ASCII format, where meaningful. In some clock drivers a good deal of additional information can be gathered and displayed as well. See information specific to each clock for further details. |
| <code>cryptostats</code> | This option requires the OpenSSL cryptographic software library. It enables recording of cryptographic public key protocol information. Each message received by the protocol module appends a line of the following form to the file generation set named <code>cryptostats</code> : 49213 525.624 127.127.4.1 message The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next field shows the peer address in dotted-quad notation. The final message field includes the message type and certain ancillary information. See the Authentication Options page for further information. |
| <code>loopstats</code> | Enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named <code>loopstats</code> : 50935 75440.031 0.000006019 13.778190 0.000351733 0.0133806 6 The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next five fields show time offset (seconds), frequency offset (parts per million - PPM), RMS jitter (seconds), Allan deviation (PPM) and clock discipline time constant. |
| <code>peerstats</code> | Enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of special signals, where present and configured. Each valid update appends a line of the following form to the current element of a file generation set named <code>peerstats</code> : 48773 10847.650 127.127.4.1 9714 -0.001605376 0.000000000 0.001424877 0.000958674 The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next two fields show the peer address in dotted-quad notation and status, respectively. The status field is encoded in hex in the format described in Appendix B of the NTP specification RFC 1305. The final four fields show the offset, delay, dispersion and RMS jitter, all in seconds. |

| Commands | Description |
|--------------------------------|---|
| rawstats | Enables recording of raw-timestamp statistics information. This includes statistics records of all peers of a NTP server and of special signals, where present and configured. Each NTP message received from a peer or clock driver appends a line of the following form to the file generation set named rawstats: <pre>50928 2132.543 128.4.1.1 128.4.1.20 3102453281.584327000 3102453281.58622800031 02453332.540806000 3102453332.541458000</pre> The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next two fields show the remote peer or clock address followed by the local address in dotted-quad notation. The final four fields show the originate, receive, transmit and final NTP timestamps in order. The timestamp values are as received and before processing by the various data smoothing and mitigation algorithms. |
| sysstats | Enables recording of ntpd statistics counters on a periodic basis. Each hour a line of the following form is appended to the file generation set named sysstats: <pre>50928 2132.543 36000 81965 0 9546 56 71793 512 540 10 147</pre> The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The remaining ten fields show the statistics counter values accumulated since the last generated line. <pre>Time since restart 36000 Time in hours since the system was last rebooted. Packets received 81965 Total number of packets received. Packets processed 0 Number of packets received in response to previous packets sent Current version 9546 Number of packets matching the current NTP version. Previous version 56 Number of packets matching the previous NTP version. Bad version 71793 Number of packets matching neither NTP version. Access denied 512 Number of packets denied access for any reason. Bad length or format 540 Number of packets with invalid length, format or port number. Bad authentication 10 Number of packets not verified as authentic. Rate exceeded 147 Number of packets discarded due to rate limitation.</pre> |
| timingstats | ONLY available when the deamon is compiled with process time debugging support (--enable-debug-timing - costs performance). Enables recording of ntpd processing time information for various selected code paths: <pre>53876 36.920 10.0.3.5 1 0.000014592 input processing delay</pre> The first two fields show the date (Modified Julian Day) and time (seconds and fraction past UTC midnight). The next field is a potential peer address, - or -REFCLOCK- depending on the associated io source. Then an event count for the number of processed events in the code path follows. The fifth field is the total time spend for the events. The rest of the line denotes the code path description statsdir directory_path . |
| statsdir directory_path | Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) filegen filename prefix to be modified for file generation sets, which is useful for handling statistics logs. |

| Commands | Description |
|--|--|
| filegen name [file filename] [type typename] [link nolink] [enable disable] | Configures setting of generation file set name. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The type given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrative operations without the risk of disturbing the operation of ntpd. (Most important: they can be removed to free space for new data produced.) Note: Note that this command can be sent from the ntpdc program running at a remote location. |
| name | This is the type of the statistics records, as shown in the statistics command. |
| file filename | This is the file name for the statistics records. Filenames of set members are built from three concatenated elements prefix, filename and suffix: |
| prefix | This is a constant filename path. It is not subject to modifications via the filegen option. It is defined by the server, usually specified as a compile-time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with loopstats and peerstats generation can be configured using the statsdir option explained above. |
| filename | This string is directly concatenated to the prefix mentioned above (no intervening / (slash)). This can be modified using the file argument to the filegen statement. No elements are allowed in this component to prevent file names referring to parts outside the file system hierarchy denoted by prefix. |
| suffix | This part reflects individual elements of a file set. It is generated according to the type of a file set. |
| type typename | A file generation set is characterized by its type. The following types are supported: |
| none | The file set is actually a single plain file. |
| pid | One element of file set is used per incarnation of a ntpd server. This type does not perform any changes to file set members during runtime, however it provides an easy way of separating files belonging to different ntpd server incarnations. The set member file name is built by appending a . (dot) to concatenated prefix and filename strings, and appending the decimal representation of the process ID of the ntpd server process |
| day | One file generation set element is created per day. A day is defined as the period between 00:00 and 24:00 UTC. The file set member suffix consists of a . (dot) and a day specification in the form YYYYMMdd. YYYY is a 4-digit year number (e.g., 1992). MM is a two-digit month number. dd is a two-digit day number. Thus, all information written at 10 December 1992 would end up in a file named prefix filename.19921210 |
| Commands | Description |
| filegen name [file filename] [type typename] [link nolink] [enable disable] | |
| week | Any file set member contains data related to a certain week of a year. The term week is defined by computing day-of-year modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set file name base: A dot, a 4-digit year number, the letter W, and a 2-digit week number. For example, information from January 10th 1992 would end up in a file with suffix 1992W1. |
| month | One generation file set element is generated per month. The file name suffix consists of a dot, a 4-digit year number, and a 2-digit month. |
| year | One generation file element is generated per year. The filename suffix consists of a dot and a 4 digit year number. |
| age | This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter a, and an 8-digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24-hour period. Information is only written to a file generation by specifying enable; output is prevented by specifying disable. |
| link nolink | It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying link and disabled using nolink. If link is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter C, and the pid of the ntpd server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name. |
| enable disable | Enables or disables the recording function. |

Miscellaneous configuration options

| Commands | Options |
|--|---|
| broadcastdelay seconds | The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the client and server. In some cases, the calibration procedure may fail due to network or server access controls, for example. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 seconds is appropriate. The default when this command is not used is 0.004 seconds. |
| calldelay delay | This option controls the delay in seconds between the first and second packets sent in burst or iburst mode to allow additional time for a modem or ISDN call to complete. |
| driftfile driftfile [minutes [tolerance]] | This command specifies the complete path and name of the file used to record the frequency of the local clock oscillator. This is the same operation as the -f command link e option. If the file exists, it is read at startup in order to set the initial frequency and then updated once per hour with the current frequency computed by the daemon. If the file name is specified, but the file itself does not exist, it starts with an initial frequency of zero and creates the file when writing it for the first time. If this command is not given, the daemon will always start with an initial frequency of zero. |
| enable [auth bclient calibrate kernel monitor ntp pps stats disable auth bclient calibrate kernel monitor ntp pps stats] | The file format consists of a single line containing a single floating point number, which records the frequency offset measured in parts-per-million (PPM). The file is updated by first writing the current drift value into a temporary file and then renaming this file to replace the old version. This implies that ntpd must have write permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should be avoided. The two optional values determine how often the file is written, and are particularly useful when it is desirable to avoid spinning up the disk unnecessarily. The parameter minutes is how often the file will be written. If omitted or less than 1, the interval will be 60 minutes (one hour). The parameter tolerance is the threshold to skip writing the new value. If the new value is within tolerance percent of the last value written (compared out to 3 decimal places), the write will be skipped. The default is 0.0, which means that the write will occur unless the current and previous values are the same. A tolerance of .1 equates roughly to a difference in the 2nd decimal place. Provides a way to enable or disable various system options. Flags not mentioned are unaffected. Note that all of these flags can be controlled remotely using the ntpdc utility program. |
| includefile includefile | auth Enables the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using either public key or private key cryptography. The default for this flag is enable bclient Enables the server to listen for a message from a broadcast or multicast server, as in the multicastclient command with default address. The default for this flag is disable. calibrate Enables the calibrate feature for reference clocks. The default for this flag is disable. kernel Enables the kernel time discipline, if available. The default for this flag is enable if support is available, otherwise disable. monitor Enables the monitoring facility. See the ntpdc program and the monlist command for further information. The default for this flag is enable ntp Enables time and frequency discipline. In effect, this switch opens and closes the feedback loop, which is useful for testing. The default for this flag is enable. pps Enables the pulse-per-second (PPS) signal when frequency and time is disciplined by the precision time kernel modifications. The default for this flag is disable. stats Enables the statistics facility. The default for this flag is disable This command allows additional configuration commands to be included from a separate file. Include files may be nested to a depth of five; upon reaching the end of any include file, command processing resumes in the previous configuration file. This option is useful for sites that run ntpd on multiple hosts, with (mostly) common options (e.g., a restriction list). |

| Commands | Options |
|----------------------------------|---|
| logconfig configkeyword | This command controls the amount and type of output written to the system syslog facility or the alternate logfile log file. All configkeyword keywords can be prefixed with =, + and -, where = sets the syslogmask, + adds and - removes messages. syslog messages can be controlled in four classes (clock, peer, sys and sync). Within these classes four types of messages can be controlled: informational messages (info), event messages (events), statistics messages (statistics) and status messages (status). Configuration keywords are formed by concatenating the message class with the event class. The all prefix can be used instead of a message class. A message class may also be followed by the all keyword to enable/disable all messages of the respective message class. By default, logconfig output is set to allsync. Thus, a minimal log configuration could look like this: <code>logconfig=syncstatus +sysevents</code> |
| | This would just list the synchronizations state of ntpd and the major system events. For a simple reference server, the following minimum message configuration could be useful: <code>logconfig=allsync +allclock</code> |
| | This configuration will list all clock information and synchronization information. All other events and messages about peers, system events and so on is suppressed. |
| logfile logfile | This command specifies the location of an alternate log file to be used instead of the default system syslog facility. This is the same operation as the -l command line option. |
| phone dial1 dial2 ... | This command is used in conjunction with the ACTS modem driver (type 18). The arguments consist of a maximum of 10 telephone numbers used to dial USNO, NIST or European time services. The Hayes command ATDT is normally prepended to the number, which can contain other modem control codes as well. |
| setvar variable [default] | This command adds an additional system variable. These variables can be used to distribute additional information such as the access policy. If the variable of the form name = value is followed by the default keyword, the variable will be listed as part of the default system variables (ntpq rv command). These additional variables serve informational purposes only. They are not related to the protocol other than they can be listed. The known protocol variables will always override any variables defined via the setvar mechanism. There are three special variables that contain the names of all variable of the same group. The sys_var_list holds the names of all system variables. The peer_var_list holds the names of all peer variables and the clock_var_list holds the names of the reference clock variables. |

| Commands | Options |
|---|---|
| tinker [allan allan dispersion dispersion freq freq huffpuff huffpuff panic panic step step stepout stepout] | This command can be used to alter several system variables in very exceptional circumstances. It should occur in the configuration file before any other configuration options. The default values of these variables have been carefully optimized for a wide range of network speeds and reliability expectations. In general, they interact in intricate ways that are hard to predict and some combinations can result in some very nasty behavior. Very rarely is it necessary to change the default values; but, some folks can't resist twisting the knobs anyway and this command is for them. Emphasis added: twisters are on their own and can expect no help from the support group. The variables operate as follows: |
| allan allan | The argument becomes the new value for the Allan intercept, which is a parameter of the PLL/FLL clock discipline algorithm. The value is in seconds with default 1500 s, which is appropriate for most computer clocks. |
| dispersion dispersion | The argument becomes the new value for the Allan intercept, which is a parameter of the PLL/FLL clock discipline algorithm. The value is in seconds with default 1500 s, which is appropriate for most computer clocks. |
| freq freq | The argument becomes the initial value of the frequency offset in parts-per-million. This overrides the value in the frequency file, if present, and avoids the initial training state if it is not. |
| huffpuff huffpuff | The argument becomes the new value for the experimental huff-n'-puff filter span, which determines the most recent interval the algorithm will search for a minimum delay. The lower limit is 900 s (15 m), but a more reasonable value is 7200 (2 hours). There is no default, since the filter is not enabled unless this command is given. |
| panic panic | The argument is the panic threshold, by default 1000 s. If set to zero, the panic sanity check is disabled and a clock offset of any value will be accepted |
| step step | The argument is the step threshold, by default 0.128 s. It can be set to any positive number in seconds. If set to zero, step adjustments will never occur. Note: The kernel time discipline is disabled if the step threshold is set to zero or greater than the default. |
| stepout stepout | The argument is the stepout timeout, by default 900 s. It can be set to any positive number in seconds. If set to zero, the stepout pulses will not be suppressed. |
| trap host_address [port port_number] [interface interface_address] | This command configures a trap receiver at the given host address and port number for sending messages with the specified local interface address. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with a source address of the local interface the message is sent through. Note that on a multihomed host the interface used may vary from time to time with routing changes. The trap receiver will generally log event messages and other information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver will ensure that no messages are lost when the server is started. |
| ttl hop ... | This command specifies a list of TTL values in increasing order. up to 8 values can be specified. In manycast mode these values are used in turn in an expanding-ring search. The default is eight multiples of 32 starting at 31. |

Network Time Protocol (NTP)

Description

NTP version 4 is compliant to RFC 2030 (Simple Network Time Protocol). It is available from AIX 6.1.

The Network Time Protocol (NTP) is widely used to synchronize a computer to Internet time servers or other sources, such as a radio or satellite receiver or telephone modem service. It provides accuracies typically less than a millisecond on LANs and up to a few milliseconds on WANs. Typical NTP configurations utilize multiple redundant servers and diverse network paths in order to achieve high accuracy and reliability.

NTP time synchronization services are widely available in the public Internet. The public NTP subnet in early 2008 includes several thousand servers in most countries and on every continent of the globe, including Antarctica. These servers support a total population estimated at over 25 million computers in the global Internet.

The NTP subnet operates with a hierarchy of levels, where each level is assigned a number called the stratum. Stratum 1 (primary) servers at the lowest level are directly synchronized to national time services. Stratum 2 (secondary) servers at the next higher level are synchronize to stratum 1 servers, and so on. Normally, NTP clients and servers with a relatively small number of clients do not synchronize to public primary servers. There are several hundred public secondary servers operating at higher strata and are the preferred choice.

NTPv3 and NTPv4 binaries coexist on AIX.

Important: By default, AIX points to NTP version 3 binaries.

NTP binaries directory mapping on AIX:

| NTPv4 Binaries | NTPv3 Binaries | Default Symbolic link to NTP version 3 binaries from /usr/sbin directory |
|-----------------------------|-----------------------------|--|
| <code>/usr/sbin/ntp4</code> | <code>/usr/sbin/ntp3</code> | <code>/usr/sbin/xntpd-->/usr/sbin/ntp3/xntpd</code> |
| <code>ntpd4</code> | <code>xntpd</code> | <code>/usr/sbin/ntpdate-->/usr/sbin/ntp3/ntpdate</code> |
| <code>ntpdate4</code> | <code>ntpdate</code> | <code>/usr/sbin/ntpdc-->/usr/sbin/ntp3/xntpdc</code> |
| <code>ntpdc4</code> | <code>xntpdc</code> | <code>/usr/sbin/ntpq-->/usr/sbin/ntp3/ntpq</code> |
| <code>ntpq4</code> | <code>ntpq</code> | <code>/usr/sbin/ntp-keygen-->/usr/sbin/ntp4/ntp-keygen4</code> |
| <code>ntp-keygen4</code> | Not Available | <code>/usr/sbin/ntptrace-->/usr/sbin/ntp3/ntptrace</code> |
| <code>ntptrace4</code> | <code>ntptrace</code> | <code>/usr/sbin/sntp-->/usr/sbin/ntp3/sntp</code> |
| <code>sntp4</code> | <code>sntp</code> | |

Note: 1 ntp-keygen is a new binary file in NTP version 4, it is not present in NTP version 3. So, the symbolic link needs to be created under `/usr/sbin` directory, pointing to `ntp4` binary (`/usr/sbin/ntp4/ntp-keygen4`). `ntptrace` file is a binary file in NTP version 3, but it is a perl script in NTP version 4.

ntp.keys File

Purpose

Contains key identifiers and keys controlling authentication of Network Time Protocol (NTP) transactions.

Description

The **ntp.keys** file contains key identifiers and keys for encryption and decryption of authentication of NTP transactions.

Authentication Key File Format

The NTP standard specifies an extension allowing verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. The **xntpd** daemon implements this by using the MD5 algorithm to compute a message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data, although they must each learn the key and key identifier independently.

The **xntpd** daemon reads its keys from a file specified with the **-k** flag or the **keys** statement in the configuration file. You cannot change key number 0 because the NTP standard fixes it as 64 zero bits.

The **ntp.keys** file uses the same comment conventions as the configuration file, **ntp.conf**. Key entries use the following format:

KeyNumber M Key

where,

| Entry | Description |
|------------------|--|
| <i>KeyNumber</i> | A positive integer |
| M | Specifies that <i>Key</i> is a 1-to-8 character ASCII string, using the MD5 authentication scheme. |
| <i>Key</i> | The key itself. |

One of the keys may be chosen, by way of the **ntp.conf** configuration file **requestkey** statement, to authenticate run-time configuration requests made using the **xntpdc** command. The **xntpdc** command obtains the key from the terminal as a password, so it is generally appropriate to specify the key in ASCII format.

Files

| Item | Description |
|----------------------|---------------------------------|
| /etc/ntp.keys | Specifies the path to the file. |

xntpd command

objects File

Purpose

Contains the audit events for audited objects (files).

Description

The **/etc/security/audit/objects** file is an ASCII stanza file that contains information about audited objects (files). This file contains one stanza for each audited file. The stanza has a name equal to the path name of the file.

Each file attribute has the following format:

```
access_mode = "audit_event "
```

An audit-event name can be up to 15 bytes long; longer names are rejected. Valid access modes are read (r), write (w), and execute (x) modes. For directories, search mode is substituted for execute mode.

The objects (files) in the **/etc/security/audit/objects** file cannot be symbolic links.

If you are using bin mode auditing, the objects designated as **bin1** and **bin2** in the **/etc/security/audit/config** file cannot be listed in the **/etc/security/audit/objects** file.

Note: The audited object files do not need to exist once the auditing starts. However, to successfully start auditing, ensure that the parent directories of the object files exist. The **audit start** command does not fail when the parent directory does not exist, but the affected files are not audited even if they are created later.

Security

Access Control: This file should grant read (r) access to the root user and members of the audit group and grant write (w) access only to the root user.

Examples

1. To define the audit events for the **/etc/security/passwd** file, add a stanza to the **/etc/security/audit/objects** file. For example:

```
/etc/security/passwd:  
  r = "S_PASSWD_READ"  
  w = "S_PASSWD_WRITE"
```

These attributes generate a **S_PASSWD_READ** audit event each time the **passwd** file is read, and a **S_PASSWD_WRITE** audit event each time the file is opened for writing.

2. To define the audit events for the **/wpars/wpar1/etc/security/passwd** file, add a stanza to the **/etc/security/audit/objects** file in the AIX system that is hosting the WPAR. For example:

```
/wpars/wpar1/etc/security/passwd:  
  r = "WPAR1_PASSWD_RD"  
  w = "WPAR1_PASSWD_WR"
```

This stanza is parsed at **audit start -@ <wpar1>** time to enable object auditing for the **/etc/security/passwd** object of **wpar1**. These attributes generate a **WPAR1_PASSWD_RD** audit event each time the **/wpars/wpar1/etc/security/passwd** file is read, and generate a **WPAR1_PASSWD_WR** audit event each time the file is opened for writing.

Files

| Item | Description |
|--------------------------------|--|
| /etc/security/audit/objects | Specifies the path to the file. |
| /etc/security/audit/config | Contains audit system configuration information. |
| /etc/security/audit/events | Contains the audit events of the system. |
| /etc/security/audit/bincmds | Contains auditbin backend commands. |
| /etc/security/audit/streamcmds | Contains auditstream commands. |

 Setting Up Auditing

pam_aix Module

Purpose

Provides AIX style authentication, account management, password management, and session management for PAM.

Description

The **pam_aix module** provides AIX style authentication behaviors to PAM. The module has support for each of the PAM module types - authentication, account management, password management and session management. Each of these types provides full AIX support for users defined in local or remote registries.

Communication from the **pam_aix** module to the user is handled through the PAM_CONV item, which is set by pam_start or pam_set_item. All messages displayed by **pam_aix** are AIX messages and are internationalized.

Typical usage for the **pam_aix** module is to be used as a backup, or "other" service. This way if a specific authentication stack is not defined for a service, local AIX authentication is used. **pam_aix** should usually be a "required" or "requisite" module. If used for password authentication, **pam_aix** should be marked as being "required" or "requisite".

```
#  

# Use AIX system authentication  

#  

OTHER auth      required pam_aix  

OTHER account   required pam_aix  

OTHER session   required pam_aix  

OTHER password  required pam_aix
```

Attention:

- The **pam_aix** module cannot be used with users who have their SYSTEM or registry user attributes set to use the **/usr/lib/security/PAM** module. In such case, an authentication loop is created, and the operation fails.
- The authentication fails if the **pam_aix** module is called from a nonroot user, and the program does not have the setuid bit set.

Supported PAM module types

Authentication

Authenticates a user through their AIX password.

Account Management

Verifies that an authenticated user is permitted onto the system and checks for expired passwords. Checks are performed through use of the `passwexpired()` and `loginrestrictions()` subroutines.

Session Management

Opens a new session and logs the session information.

Password Management

Allows a user to set or modify their AIX password if it is possible. `pam_aix` will then update the user's password entry in the appropriate password table. When `pam_aix` is used for password management, it should be used as "required" or "requisite".

Options

The `pam_aix` module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|-----------------------------|--|
| <code>debug</code> | Log debugging information to syslog. |
| <code>mode</code> | Specifying the mode option for a service allows the login restrictions checks to be customized as needed for a PAM service. The value specified for <code>mode</code> can be one of the following strings: <ul style="list-style-type: none">• <code>S_DAEMON</code>• <code>S_LOGIN</code>• <code>S_RLOGIN</code>• <code>S_SU</code>• <code>S_DIST_CLNT</code>• <code>S_DIST_SERV</code> The checks performed by each mode are defined in the <code>loginrestrictions</code> subroutine man page. If the option is not specified, then a mode of 0 is passed into the subsequent <code>loginrestrictions</code> invocation. This option is only valid for the Authentication and Account Management module types. |
| <code>nowarn</code> | Do not display warning messages. |
| <code>no_pwd_ck</code> | Do not check for password expiration. |
| <code>use_first_pass</code> | Use a previously entered password, do not prompt for a new one. |
| <code>try_first_pass</code> | Try a previously entered password. If it fails, prompt for a new one. |
| <code>use_new_state</code> | AIX builds and maintains state information when authenticating a user. By default, the <code>pam_aix</code> module will use the same state information throughout a PAM session. This can produce results that are correct in terms of AIX authentication but are unexpected within the PAM framework. For example, <code>pam_authenticate</code> requests may fail due to access restrictions. If this behavior is not desired for a given module type, specify the <code>use_new_state</code> option to use new state information for each invocation. |

Return Values

Upon successful completion the `pam_aix` module returns `PAM_SUCCESS`. If a failure occurs a PAM error code will be returned, depending on the actual error.

Location

`/usr/lib/security/pam_aix`

`/usr/lib/security/64`

Related information:

`loginrestrictions` subroutine
Pluggable Authentication Modules

pam_allow Module

Purpose

Returns PAM_SUCCESS for all PAM module types.

Description

The **pam_allow** module returns PAM_SUCCESS to all calling applications unless an invalid PAM handle is specified. Support for all four module types is provided.

Attention: This module should be used with caution and should often only be used for PAM debugging purposes. Placing this module in the PAM stack for a service could potentially grant access to all users.

Functionality opposite to that provided by **pam_allow** can be obtained through use of the **pam_prohibit** module.

Supported PAM module types

Authentication

Returns PAM_SUCCESS if valid PAM handle.

Account Management

Returns PAM_SUCCESS if valid PAM handle.

Session Management

Returns PAM_SUCCESS if valid PAM handle.

Password Management

Returns PAM_SUCCESS if valid PAM handle.

Options

The **pam_allow** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|---------------------|--|
| <code>debug</code> | Log debugging information to <code>syslog</code> . |
| <code>nowarn</code> | Do not display warning messages. |

Return Values

Upon successful completion the **pam_allow** module returns PAM_SUCCESS. If an invalid PAM handle was specified, PAM_SYSTEM_ERR is returned.

Location

`/usr/lib/security/pam_allow`

pam_open_session subroutine
pam_close_session subroutine

pam_allowroot Module

Purpose

Returns PAM_SUCCESS if the authenticating user has a real user ID (UID) of 0.

Description

The **pam_allowroot** module checks the real user ID (UID) under which the PAM application was run. If the UID of the authenticating user is 0 (zero), then it is the root user and PAM_SUCCESS is returned.

The **pam_allowroot** module only checks the real user ID. Many applications that require root access will set the effective user ID to 0. For this reason, the effective ID is not used in determining whether or not the user executing the authenticating application is a root user.

It is recommended that **pam_allowroot** be used as sufficient in conjunction with other modules. This allows the root user to bypass the rest of the modules in the stack and for a failure not to impact the result of other authenticating users. An example authentication stack configuration is shown below which mimics the historic behavior of the **su** command.

```
#  
# The PAM configuration for standard su behavior.  
#  
su auth sufficient /usr/lib/security/pam_allowroot  
su auth required   /usr/lib/security/pam_aix
```

Supported PAM module types

Authentication

Returns PAM_SUCCESS if UID of authenticating user is 0.

Account Management

Returns PAM_SUCCESS if UID of authenticating user is 0.

Options

The **pam_allowroot** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|---------------|--|
| <i>debug</i> | Log debugging information to syslog . |
| <i>nowarn</i> | Do not display warning messages. |

Return Values

Upon successful completion, PAM_SUCCESS is returned. If a failure occurs, a PAM error code will be returned, depending on the actual error.

Location

/usr/lib/security/pam_allowroot

Related information:

pam_authenticate subroutine

pam_setcred subroutine

Pluggable Authentication Modules

pam_ckfile Module

Purpose

Denies all non-root user logins if **/etc/nologin** or an optionally specified file is present.

Description

The **pam_ckfile** module allows or denies authentication, based on the existence of a file. The file checked for existence can be set with the **file=<filename>** module option. If not specified the file defaults to **/etc/nologin**.

If the specified file exists, only root users (those with a user ID of 0) may authenticate. All other users are denied access for the service, and **pam_ckfile** will echo the contents (if any) of that file. If the specified file does not exist, the module returns PAM_IGNORE. System administrators should ensure that success or failure of the module stack for a service does not depend solely on the result of this module.

It is recommended that **pam_ckfile** is used as "required" or "requisite" in conjunction with other modules. An example authentication stack is provided below to demonstrate how **/etc/nologin** behavior with the login service can be implemented.

```
#  
# Provide the standard /etc/nologin behavior for login.  
#  
login auth required    /usr/lib/security/pam_ckfile file=/etc/nologin  
login auth required    /usr/lib/security/pam_aix
```

Supported PAM module types

Authentication

Denies non-root user authentication if the specified file is present.

Account Management

Denies account access for non-root users if the specified file is present.

Options

The **pam_allowroot** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|------------------------------------|---|
| <code>debug</code> | Log debugging information to syslog . |
| <code>nowarn</code> | Do not display warning messages. |
| <code>file=<filename></code> | Use <code><filename></code> instead of /etc/nologin . Note: <code><filename></code> must be the full path to the file. |

Return Values

Upon successful completion PAM_SUCCESS is returned. If the specified file does not exist the module returns PAM_IGNORE. If another failure occurs, a PAM error code will be returned, depending on the actual error.

Pluggable Authentication Modules

pam_mkuserhome Module

Purpose

Creates a home directory automatically at user login.

Location

/usr/lib/security

/usr/lib/security/64

Description

The **pam_mkuserhome** module creates a home directory automatically at user login. This is an optional session module to be used with other PAM session modules, such as the **pam_aix** module.

The **pam_mkuserhome** module is installed in the **/usr/lib/security** directory. To use the **pam_mkuserhome** module, the **/etc/pam.conf** file must be configured. Stacking is still available but is not shown in the following example of the **/etc/pam.conf** file:

```
#  
# Session management  
#  
telnet auth optional pam_mkuserhome
```

Return Value

| Item | Description |
|------------------|--|
| PAM_SUCCESS | The home directory already exists or the home directory is successfully created. |
| PAM_USER_UNKNOWN | The user does not exist. |
| PAM_SYSTEM_ERR | An error occurs. |

pam_aix module

Automatic home directory creation at login

Pluggable Authentication Modules

pam_permission Module

Purpose

Allows or prohibits authentication through a configurable file containing a list of users and/or groups.

Description

The **pam_permission** module is an authentication and account-service PAM module that uses an access-control list to determine whether or not to permit or deny authentication requests. The file to use for the control list is configured via a module option and defaults to **/etc/ftpusers** if not specified.

If the access-control file exists, the **pam_permission** module will scan the file using the authenticating user name and group(s). The first match will then be used to determine the result. The general syntax for an entry in the access-control file is as follows:

[+|-] [@]<name>

The optional first character controls whether to allow(+) or deny(-) the request for the user or group specified by <name>. If a '+' or '-' is not the first character in an entry, then the value of the found=<action> module option determines the behavior.

Preceding a name by the '@' symbol designates the entry as a group. Otherwise the entry is used as a user name. The first match found to a user name or group entry is used to determine access.

All spaces in an entry are ignored. Comments may be added to the file using the '#' character as the first character in the line. Only one entry or comment is allowed per line and the entries are processed one at a time, sequentially, starting at the top of the file.

Using the keyword "ALL" for <name> will match all users. Since the file is parsed sequentially, use of the "ALL" keyword should be reserved for the end of the file as any entries after it are ignored.

Upon reaching the end of the access-control file, if a match to a user name or group has not been made, the result will be the opposite value of the found=<action> module option. For example, if **found=prohibit** is set and the user is not found within the file, then the result for that user would be allow.

If the specified access control file does not exist, the module will return PAM_IGNORE and have no affect on the module stack. It is not recommended that the overall success or failure of the module stack depend solely on **pam_permission**.

It is recommended that **pam_permission** is used as "required" or "requisite" in conjunction with other modules. An example authentication stack is provided below to demonstrate how **/etc/ftpusers** behavior with the **ftp** service can be implemented.

```
#  
# Provide /etc/ftpusers access-control  
# to PAM-enabled ftp.  
#  
ftp auth requisite  /usr/lib/security/pam_permission  
                    file=/etc/ftpusers  found=prohibit  
ftp auth required   /usr/lib/security/pam_aix
```

Supported PAM module types

Authentication

Provides user authentication based on the contents of the access-control file.

Account Management

Provides account access and denial based upon the rules in the access-control file.

Options

The **pam_permission** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|---------------------------------------|---|
| <code>debug</code> | Log debugging information to <code>syslog</code> . |
| <code>nowarn</code> | Do not display warning messages. |
| <code>file=<filename></code> | Use <filename> as access control file. Defaults to <code>/etc/ftpusers</code> . |
| <code>found=(allow prohibit)</code> | Action if an entry match was found but is not preceded by a '+' or '-'. Default is prohibit . |

Return Values

Upon successful completion PAM_SUCCESS is returned. If a failure occurs, a PAM error code will be returned, depending on the actual error.

Location

`/usr/lib/security/pam_permission`

Related reference:

"pam.conf File" on page 208

Related information:

`pam_authenticate` subroutine

`pam_acct_mgmt` subroutine

Pluggable Authentication Modules

pam_prohibit Module

Purpose

Returns a value denoting a failure for each PAM module type.

Description

The `pam_prohibit` module returns a failure for all PAM module types. If used as a required or requisite module for a service, the stack that this module is incorporated into will always fail. It is recommended that individual services be explicitly configured in `/etc/pam.conf` and then the `pam_prohibit` module used for the OTHER service entries. Configuring the system in this way ensures that only known PAM enabled applications are capable of successfully authenticating users. Listed below is an example of how to configure the OTHER service keyword in `/etc/pam.conf` to use the `pam_prohibit` module:

```
#  
# Fail for all PAM services not explicitly configured  
#  
OTHER auth    required /usr/lib/security/pam_prohibit  
OTHER account  required /usr/lib/security/pam_prohibit  
OTHER password required /usr/lib/security/pam_prohibit  
OTHER session  required /usr/lib/security/pam_prohibit
```

Functionality opposite to that provided by `pam_prohibit` can be obtained by using the `pam_allow` module.

Supported PAM module types

Authentication

`pam_sm_authenticate` returns PAM_AUTH_ERR `pam_sm_setcred` returns PAM_CRED_ERR

Account Management

`pam_sm_acct_mgmt` returns PAM_ACCT_EXPIRED

Session Management

`pam_sm_open_session` returns PAM_SESSION_ERR

Password Management

pam_sm_chauthok returns PAM_AUTHOK_ERR

Options

The **pam_prohibit** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|---------------|--|
| debug | Log debugging information to syslog . |
| nowarn | Do not display warning messages. |

Return Values

The **pam_prohibit** module will never return PAM_SUCCESS. If an invalid PAM handle is found then PAM_SYSTEM_ERR is returned, otherwise the error code returned is PAM module type specific.

Location

/usr/lib/security/pam_prohibit

Related reference:

“**pam_allow** Module” on page 201

Related information:

pam_acct_mgmt subroutine

pam_close_session subroutine

Pluggable Authentication Modules

pam_rhosts_auth Module

Purpose

Provides **rhosts**-based authentication for PAM.

Description

The **pam_rhosts_auth** module provides rhost authentication services similar to the **rlogin**, **rsh**, and **rcp** commands. The module queries the PAM handle for the remote user name, remote host, and the local user name. This information is then compared to the rules in **/etc/hosts.equiv** and **\$HOME/.rhosts**.

For a typical user, the module first checks **/etc/hosts.equiv**. If a match is not found for the username and hostname, the module will continue on to check the **\$HOME/.rhosts** file. If a username and hostname match is still not found, the module returns the PAM_AUTH_ERR failure code. Otherwise, the result depends on the first rule found matching the specified username and hostname.

When authenticating to the root user (user with the UID of 0), the first check of the **/etc/hosts.equiv** file is skipped. Success of the **rhosts** authentication is based solely on the contents of the root user's **\$HOME/.rhosts** file.

This module requires that a PAM application, before making the call to **pam_authenticate**, call **pam_set_item** and at least set the values of PAM_RHOST and PAM_RUSER. If the PAM_USER item is not set, the module will prompt for the user name through the conversation function provided in the PAM handle.

Further description on how **rhosts** authentication works can be found in the documentation for the **ruserok()** subroutine. Information regarding the syntax of **rhost** configuration files can be found in the **\$HOME/.rhosts** or **/etc/hosts.equiv** files description.

For expected behavior, **pam_rhosts_auth** should be used as one of the first authentication modules in the stack and designated as sufficient.

```
#  
# PAM authentication stack for typical rlogin behavior.  
#  
rlogin auth sufficient /usr/lib/security/pam_rhosts_auth  
rlogin auth required   /usr/lib/security/pam_aix
```

Supported PAM module types

Authentication

Authenticates a user through **rhost**-based authentication.

Options

The **pam_rhosts_auth** module accepts the following parameters specified as options in the PAM configuration file:

| Item | Description |
|---------------|--|
| debug | Log debugging information to syslog . |
| nowarn | Do not display warning messages. |

Return Values

Upon successful completion **PAM_SUCCESS** is returned. If a failure occurs, a PAM error code will be returned, depending on the actual error.

Location

/usr/lib/security/pam_rhosts_auth

pam_authenticate subroutine

ruserok command

rlogin Command

Pluggable Authentication Modules

pam.conf File

Purpose

Contains service entries for each PAM (Pluggable Authentication Modules) module type.

Description

The **/etc/pam.conf** configuration file consists of service entries for each PAM module type and serves to route services through a defined module path. Entries in the file are composed of the following whitespace-delimited fields: **service_name module_type control_flag module_path module_options**

| Item | Description |
|-----------------------|--|
| <i>service_name</i> | Specifies the name of the PAM enabled service. The keyword OTHER is used to define the default module to use for applications not specified in an entry. |
| <i>module_type</i> | Specifies the module type for the service. Valid module types are auth , account , session , or password . A given module will provide support for one or more module types. |
| <i>control_flag</i> | <p>Specifies the stacking behavior for the module. Supported control flags are required, requisite, sufficient, or optional.</p> <p>required All required modules in a stack must pass for a successful result. If one or more of the required modules fail, all of the required modules in the stack will be attempted, but the error from the first failed required module is returned.</p> <p>requisite Similar to required except that if a requisite module fails, no further modules in the stack are processed and it immediately returns the first failure code from a required or requisite module.</p> <p>sufficient If a module flagged as sufficient succeeds and no previous required modules have failed, all remaining modules in the stack are ignored and success is returned.</p> <p>optional If none of the modules in the stack are required and no sufficient modules have succeeded, then at least one optional module for the service must succeed. If another module in the stack is successful, a failure in an optional module is ignored.</p> |
| <i>module_path</i> | <p>Specifies the module to load for the service. Valid values for <i>module_path</i> may be specified as either the full path to the module or just the module name. If the full path to the module is not specified, the PAM library prepends /usr/lib/security (for 32-bit services) or /usr/lib/security/64 (for 64-bit services) to the module name.</p> <p>If the module path is specified as full path, then it directly uses for 32-bit services, for 64-bit services module path derived as <i>module_path/64/module_name</i>.</p> |
| <i>module_options</i> | Specifies a space delimited list of module specific options. Values for this field are dependent on the options supported by the module defined in the module_path field. This field is optional. |

Malformed entries, or entries with invalid values for the **module_type** or **control_flag** fields are ignored by the PAM library. Entries beginning with a number sign (#) character at the beginning of the line are also ignored as this denotes a comment.

PAM supports a concept typically referred to as stacking, which allows multiple mechanisms to be used for each service. Stacking is implemented in the configuration file by creating multiple entries for a service with the same **module_type** field. The modules are invoked in the order in which they are listed in the file for a given service name, with the final result determined by the **control_flag** field specified for each entry.

The following **/etc/pam.conf** subset is an example of stacking in the **auth** module type for the login service.

```

#
# PAM configuration file /etc/pam.conf
#
# Authentication Management
login auth required      /usr/lib/security/pam_ckfile    file=/etc/nologin
login auth required      /usr/lib/security/pam_aix
login auth optional     /usr/lib/security/pam_test      use_first_pass
OTHER  auth required     /usr/lib/security/pam_prohibit

```

The example configuration file contains three entries for the login service. Having specified both **pam_ckfile** and **pam_aix** as required, both modules will be executed and both must be successful for the overall result to be success. The third entry for the fictitious **pam_test** module is optional and its success or failure will not affect whether the user is able to login. The option **use_first_pass** to the **pam_test** module requires that a previously entered password be used instead of prompting for a new one.

Use of the OTHER keyword as a service name enables a default to be set for any other services that are not explicitly declared in the configuration file. Setting up a default ensures that all cases for a given module type will be covered by at least one module. In the case of this example, all services other than login will always fail since the pam_prohibit module returns a PAM failure for all invocations.

Changing the /etc/pam.conf File

When changing the `/etc/pam.conf` configuration file, consider the following:

- The file should always be owned by the root user and group security. Permission on the file should be set to 644 to allow everyone read access, but only allow root to modify it.
- For greater security, consider explicitly configuring each PAM enabled service and then using the `pam_prohibit` module for the OTHER service keyword.
- Read any documentation supplied for a chosen module and service, and determine which control flags, options and module types are supported and what their impact will be.
- Select the ordering of modules and control flags carefully, keeping in mind the behavior of required, requisite, sufficient, and optional control flags in stacked modules.

Note: Incorrect configuration of the PAM configuration file can result in a system that cannot be logged in to since the configuration applies to all users, including root. After making changes to the file, always test the affected applications before logging out of the system. A system that cannot be logged in to can be recovered by booting the system in maintenance mode and correcting the `/etc/pam.conf` configuration file.

Files

| Item | Description |
|----------------------------|---|
| <code>/etc/pam.conf</code> | Location of the <code>pam.conf</code> configuration file. |

/etc/passwd File

Purpose

Contains basic user attributes.

Description

The `/etc/passwd` file contains basic user attributes. This is an ASCII file that contains an entry for each user. Each entry defines the basic attributes applied to a user. When you use the `mkuser` command to add a user to your system, the command updates the `/etc/passwd` file.

Note: Certain system-defined group and user names are required for proper installation and update of the system software. Use care before replacing this file to ensure that no system-supplied groups or users are removed.

An entry in the `/etc/passwd` file has the following form:

Name:Password: UserID:PrincipleGroup:Gecos: HomeDirectory:Shell

Attributes in an entry are separated by a : (colon). For this reason, you should not use a : (colon) in any attribute. The attributes are defined as follows:

| Attribute | Definition |
|-----------------------|--|
| <i>Name</i> | Specifies the user's login name. There are a number of restrictions on naming users. See the mkuser command for more information. |
| <i>Password</i> | Contains an * (asterisk) indicating an invalid password or an ! (exclamation point) indicating that the password is in the /etc/security/passwd file. Under normal conditions, the field contains an !. If the field has an * and a password is required for user authentication, the user cannot log in. |
| <i>UserID</i> | Specifies the user's unique numeric ID. This ID is used for discretionary access control. The value is a unique decimal integer. |
| <i>PrincipleGroup</i> | Specifies the user's principal group ID. This must be the numeric ID of a group in the user database or a group defined by a network information service. The value is a unique decimal integer. |
| <i>Gecos</i> | Specifies general information about the user that is not needed by the system, such as an office or phone number. The value is a character string. The <i>Gecos</i> field cannot contain a colon. |
| <i>HomeDirectory</i> | Specifies the full path name of the user's home directory. If the user does not have a defined home directory, the home directory of the guest user is used. The value is a character string. |
| <i>Shell</i> | Specifies the initial program or shell that is executed after a user invokes the login command or su command. If a user does not have a defined shell, /usr/bin/sh , the system shell, is used. The value is a character string that may contain arguments to pass to the initial program. |

Users can have additional attributes in other system files. See the "Files" section for additional information.

Changing the User File

You should access the user database files through the system commands and subroutines defined for this purpose. Access through other commands or subroutines may not be supported in future releases. Use the following commands to access user database files:

- **chfn**
- **chsh**
- **chuser**
- **lsuser**
- **mkuser**
- **rmuser**

The **mkuser** command adds new entries to the **/etc/passwd** file and fills in the attribute values as defined in the **/usr/lib/security/mkuser.default** file.

The *Password* attribute is always initialized to an * (asterisk), an invalid password. You can set the password with the **passwd** or **pwdadm** command. When the password is changed, an ! (exclamation point) is added to the **/etc/passwd** file, indicating that the encrypted password is in the **/etc/security/passwd** file.

Use the **chuser** command to change all user attributes except *Password*. The **chfn** command and the **chsh** command change the *Gecos* attribute and *Shell* attribute, respectively. To display all the attributes in this file, use the **lsuser** command. To remove a user and all the user's attributes, use the **rmuser** command.

To write programs that affect attributes in the **/etc/passwd** file, use the subroutines listed in the related information section.

Security

Access Control: This file should grant read (r) access to all users and write (w) access only to the root user and members of the security group.

Examples

1. Typical records that show an invalid password for smith and guest follow:

```
smith:*:100:100:8A-74(office):/home/smith:/usr/bin/sh  
guest:*:200:0:/home/guest:/usr/bin/sh
```

The fields are in the following order: user name, password, user ID, primary group, general (gecos) information, home directory, and initial program (login shell). The * (asterisk) in the password field indicates that the password is invalid. Each attribute is separated by a : (colon).

2. If the password for smith in the previous example is changed to a valid password, the record will change to the following:

```
smith!:100:100:8A-74(office):/home/smith:/usr/bin/sh
```

The ! (exclamation point) indicates that an encrypted password is stored in the */etc/security/passwd* file.

Files

| Item | Description |
|---|--|
| <i>/etc/passwd</i> | Contains basic user attributes. |
| <i>/usr/lib/security/mkuser.default</i> | Contains default attributes for new users. |
| <i>/etc/group</i> | Contains the basic attributes of groups. |
| <i>/etc/security/group</i> | Contains the extended attributes of groups. |
| <i>/etc/security/passwd</i> | Contains password information. |
| <i>/etc/security/user</i> | Contains the extended attributes of users. |
| <i>/etc/security/environ</i> | Contains the environment attributes of users. |
| <i>/etc/security/limits</i> | Contains the process resource limits of users. |

User Accounts

passwd_policy File

Purpose

Defines the types and manifest constants required to support the **passwdpolicy()** function.

Description

The **passwdpolicy()** interface uses named policies to determine the strength of a new password. This interface is intended for applications which maintain policy information in either the per-user attribute databases (for example */etc/security/user*) or which use the new policy files (*/etc/security/passwd_policy* and */usr/lib/security/passwd_policy*) to create password policies which are not associated with a specific user.

System security applications may name policies which are then enforced using the named rules in */etc/security/passwd_policy*. Because this file resides in the */etc/security* directory, it is only accessible by

applications run by root or a member of group security. The `/usr/lib/security/passwd_policy` file is intended for applications which wish to use these new APIs to enforce their own password strength rules. There is no support for a default stanza, rather each application must name a stanza it wishes to use as the default and then explicitly check against that stanza. In addition to the basic construction rules which are supported by `passwdstrength()`, this interface supports dictionary checking, per-user password histories, and administrator-defined load module extensions.

The format of the `passwd_policy` file is similar to the password construction rule attributes as stored in the `/etc/security/user` file, with the exception that named policies do not include the histsize and histexpire attributes. Each file is a sequence of zero or more stanzas with the named policy being the stanza name. Each stanza contains one or more attributes describing the password rules which must be satisfied for a password to be accepted.

Example

```
ibm_corp_policy:  
    dictlist = /usr/share/dict/words,/usr/local/lib/local_words  
    maxage = 26  
    minage = 2  
    maxexpired = 2  
    maxrepeats = 2  
    mindiff = 6  
    minalpha = 4  
    minother = 2  
    minlen = 7  
    pwdchecks = /usr/lib/security/more_checks.so
```

The maxage, minage, maxexpired, maxrepeats, mindiff, minalpha, minother, and minlen attributes are integers. The dictlist and pwdchecks attributes are comma-separated lists of filenames. For more information on valid values for attributes, please see `/etc/security/user`.

Permissions

The permissions on `/etc/security/passwd_policy` shall be 660, owner `root`, group `security`. This restricts access to processes with the privileges needed to perform other security administrative tasks. The permissions on `/usr/lib/security/passwd_policy` shall be 664, owner `root`, group `security`. This allows all processes to read the file, while restricting administrative access to processes with the privileges needed to perform other security administrative tasks. Applications select between policy files using the type parameter to the `pwdpolicy()` function.

Location

| Item | Description |
|--|---|
| <code>/usr/lib/security/passwd_policy</code> | Location of policy values for PWP_LOCALPOLICY. |
| <code>/etc/security/passwd_policy</code> | Location of policy values for PWP_SYSTEMPOLICY. |

/etc/security/passwd File

Purpose

Contains password information.

Description

The **/etc/security/passwd** file is an ASCII file that contains stanzas with password information. Each stanza is identified by a user name followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute is ended with a new line character, and each stanza is ended with an additional new line character.

Each stanza can have the following attributes:

| Attribute | Definition |
|-------------------|--|
| password | Specifies the encrypted password. The system encrypts the password created with the passwd command or the pwdadm command. If the password is empty, the user does not have a password. If the password is an * (asterisk), the user cannot log in. The value is a character string. The default value is *. |
| lastupdate | Specifies the time (in seconds) since the epoch (00:00:00 GMT, January 1, 1970) when the password was last changed. If password aging (the minage attribute or the maxage attribute) is in effect, the lastupdate attribute forces a password change when the time limit expires. (See the /etc/security/user file for information on password aging.) The passwd and pwdadm commands normally set this attribute when a password is changed. The value is a decimal integer that can be converted to a text string using the ctime subroutine. |
| flags | Specifies the restrictions applied by the login , passwd , and su commands. The value is a list of comma-separated attributes. The flags attribute can be left blank or can be one or more of the following values: ADMIN Defines the administrative status of the password information. If the ADMIN attribute is set, only the root user can change this password information. ADMCHG Indicates that the password was last changed by a member of the security group or the root user. Normally this flag is set implicitly when the pwdadm command changes another user's password. When this flag is set explicitly, it forces the password to be updated the next time a user gives the login command or the su command. NOCHECK None of the system password restrictions defined in the /etc/security/user file are enforced for this password. |

When the **passwd** or **pwdadm** command updates a password, the command adds values for the **password** and **lastupdate** attributes and, if used to change another user's password, for the **flags ADMCHG** attribute.

Access to this file should be through the system commands and subroutines defined for this purpose. Other accesses may not be supported in future releases. Users can update their own passwords with the **passwd** command, administrators can set passwords and password flags with the **pwdadm** command, and the root user is able to use the **passwd** command to set the passwords of other users.

Refer to the "Files" section for information on where attributes and other information on users and groups are stored.

Although each user name must be in the **/etc/passwd** file, it is not necessary to have each user name listed in the **/etc/security/passwd** file. If the authentication attributes **auth1** and **auth2** are so defined in the **/etc/security/user** file, a user may use the authentication name of another user. For example, the authentication attributes for user tom can allow that user to use the entry in the **/etc/security/passwd** file for user carol for authentication.

Security

Access Control: This file should grant read (r) and write (w) access only to the root user.

Auditing Events:

| Event | Information |
|----------------|-------------|
| S_PASSWD_READ | file name |
| S_PASSWD_WRITE | file name |

Examples

The following line indicates that the password information in the **/etc/security/passwd** file is available only to the root user, who has no restrictions on updating a password for the specified user:

```
flags = ADMIN,NOCHECK
```

An example of this line in a typical stanza for user **smith** follows:

```
smith:
password = MGURSJ.F056Dj
lastupdate = 623078865
flags = ADMIN,NOCHECK
```

The **password** line shows an encrypted password. The **lastupdate** line shows the number of seconds since the epoch that the password was last changed. The **flags** line shows two flags: the **ADMIN** flag indicates that the information is available only to the root user, and the **NOCHECK** flag indicates that the root user has no restrictions on updating a password for the specified user.

Files

| Item | Description |
|--------------------------------|---|
| /etc/security/passwd | Specifies the path to the file. |
| /etc/passwd | Contains basic user attributes. |
| /etc/security/user | Contains the extended attributes of users. |
| /etc/security/login.cfg | Contains configuration information for login and user authentication. |

pcnfsd.conf Configuration File

Purpose

Provides configuration options for the **rpc.pcnfsd** daemon.

Description

The **/etc/pcnfsd.conf** file is an ASCII file written by users to add options to the operation of the **rpc.pcnfsd** daemon, which takes no command-line flags. This file is part of Network Support Facilities.

When started, the **rpc.pcnfsd** daemon checks for the presence of the **pcnfsd.conf** configuration file and conforms its performance to the specified arguments. The following options can be entered in the **pcnfsd.conf** file:

Option**aixargs -B***CharacterPair***Description**

Controls the printing of burst pages according to the value of the *CharacterPair* variable, as listed below. The first character applies to the header and the second character to the trailer. Possible values are **n** (never), **a** (always), and **g** (group).

| HT | Description |
|-----------|--|
| nn | No headers, no trailers |
| na | No headers, trailer on every file |
| ng | No header, trailer at the end of the job |
| an | Header on every file, no trailers |
| aa | Headers and trailers on every file in the job |
| ag | Header on every file, trailer after job |
| gn | Header at beginning of job, no trailer |
| ga | Header at beginning of job, trailer after every file |
| gg | Header at beginning of job, trailer at end of job |

The header and trailer stanzas in the */etc/qconfig* file define the default treatment of burst pages.

Note: The **-B** flag works exactly like the **-B** flag in the **enq** command. Unlike the **enq** command, however, the **rpc.pcnfsd** daemon does not allow spaces between the **-B** flag and the *CharacterPair* variable.

getjobnum off

Disables the **rpc.pcnfsd** daemon feature that returns job numbers when print jobs are submitted.

printer *Name AliasFor Command*

Defines a PC-NFS virtual printer, recognized only by **rpc.pcnfsd** daemon clients. Each virtual printer is defined on a separate line in the **pcnfsd.conf** file. The following variables are specified with this option.

| | |
|-----------------|---|
| <i>Name</i> | Specifies the name of the PC-NFS virtual printer to be defined. |
| <i>AliasFor</i> | Specifies the name of an existing printer that performs the print job. |
| | Note: To define a PC-NFS virtual printer associated with no existing printer, use a single - (minus sign) instead of the <i>AliasFor</i> variable. |

Command

Specifies the command that is run when a file is printed on the *Name* printer. This command is executed by the Bourne shell, using the **-c** option. For complex operations, replace the *Command* variable with an executable shell script.

The following list of tokens and substitution values can be used in the *Command* variable:

| Token | Substitution Value |
|---------------|---|
| \$FILE | The full path name of the print data file. After the command has executed, the file will be unlinked. |
| \$USER | The user name of the user logged in to the client. |
| \$HOST | The host name of the client system. |

spooldir *PathName*

Designates a new parent directory, *PathName*, where the **rpc.pcnfsd** daemon stores the subdirectories it creates for each of its clients. The default parent directory is */var/spool/pcnfs*.

| Option | Description |
|----------|---|
| uidrange | Specifies the valid UID (user number) range that the rpc.pcnfsd daemon accepts. The default UID range is 101-4294967295. |
| wtmp off | Disables the login record-keeping feature of the rpc.pcnfsd daemon. By default, the daemon appends to the /var/adm/wtmp file a record of user logins. |

Examples

1. The following sample **pcnfsd.conf** configuration file demonstrates the effects some options have on the operation of the **rpc.pcnfsd** daemon:

```
printer test - /usr/bin/cp $FILE
/usr/tmp/$HOST-$USER
printer sandman san ls -l $FILE
wtmp off
```

The first line establishes a printer test. Files sent to the test printer will be copied into the **/usr/tmp** directory. Requests to the test PC-NFS virtual printer to list the queue, check the status, or do similar printer operations, will be rejected because a **-** (minus sign) has been given for the *Alias-For* parameter.

The second line establishes a PC-NFS virtual printer called **sandman** that lists, in long form, the file specifications for the print data file.

The third line turns off the **rpc.pcnfsd** daemon feature that records user logins.

2. To set a UID range enter:

```
uidrange 1-100,200-50000
```

This entry means that only numbers from 101-199 and over 50000 are invalid UID numbers.

Files

| Item | Description |
|-----------------------------------|--|
| /etc/pcnfsd.conf | Specifies the path of the configuration file. |
| /var/spool/pcnfs directory | Contains subdirectories for clients of the pcnfsd daemon. |
| /etc/qconfig | Configures a printer queuing system. |
| /var/adm/wtmp | Describes formats for user and accounting information. |

pkginfo File

Purpose

Describes the format of a package characteristics file.

Description

The **pkginfo** file is an ASCII file that describes the characteristics of the package along with information that helps control the flow of installation. It is created by the software package developer.

Each entry in the **pkginfo** file is a line that establishes the value of a parameter in the following form:

PARAM="value"

There is no required order in which the parameters must be specified within the file. Each parameter is described below. Only fields marked with an asterisk are mandatory.

| Parameter | Description |
|--------------------|---|
| PKG* | PKG is the parameter to which you assign an abbreviation for the name of the package being installed. The abbreviation must be a short string (no more than nine characters long) and it must conform to file naming rules. All characters in the abbreviation must be alphanumeric and the first cannot be numeric. install , new , and all are reserved abbreviations. |
| NAME* | Text that specifies the package name (maximum length of 256 ASCII characters). |
| ARCH* | A comma-separated list of alphanumeric tokens that indicate the architecture (for example, ARCH=m68k,i386) associated with the package. The pkgmk(1M) tool can be used to create or modify this value when actually building the package. The maximum length of a token is 16 characters and it cannot include a comma. |
| VERSION* | Text that specifies the current version associated with the software package. The maximum length is 256 ASCII characters and the first character cannot be a left parenthesis. The pkgmk tool can be used to create or modify this value when actually building the package. |
| CATEGORY* | A comma-separated list of categories under which a package can be displayed. There are six categories: "application," "graphics," "system," "utilities," "set," and "patch." If you choose, you can also assign a package to one or more categories that you define. Categories are case-insensitive and can contain only alphanumerics. Each category is limited in length to 16 characters. |
| | For a Set Installation Package (SIP), this field must have the value "set." A SIP is a special purpose package that controls the installation of a set of packages. |
| DESC | Text that describes the package (maximum length of 256 ASCII characters). |
| VENDOR | Used to identify the vendor that holds the software copyright (maximum length of 256 ASCII characters). |
| HOTLINE | Phone number and/or mailing address where further information can be received or bugs can be reported (maximum length of 256 ASCII characters). |
| EMAIL | An electronic address where further information is available or bugs can be reported (maximum length of 256 ASCII characters). |
| VSTOCK | The vendor stock number, if any, that identifies this product (maximum length of 256 ASCII characters). |
| CLASSES | A space-separated list of classes defined for a package. The order of the list determines the order in which the classes are installed. Classes listed first are installed first (on a medium-by-medium basis). This parameter can be modified by the request script. In this way, the request script can be used to select which classes in the package get installed on the system. |
| ISTATES | A list of allowable run states for package installation (for example, ""S s 1""). |
| RSTATES | A list of allowable run states for package removal (for example, ""S s 1""). |
| BASEDIR | The pathname to a default directory where "relocatable" files can be installed. If BASEDIR is not specified and basedir in the admin file (<i>/var/sadm/install/admin/default</i>) is set to default , then BASEDIR is set to / by default. An administrator can override the value of BASEDIR by setting basedir in the admin file. |
| ULIMIT | If set, this parameter is passed as an argument to the ulimit command, which establishes the maximum size of a file during installation. |
| ORDER | A list of classes defining the order in which they should be put on the medium. Used by pkgmk(1) in creating the package. Classes not defined in this field are placed on the medium using the standard ordering procedures. |
| PSTAMP | Production stamp used to mark the pkgmap(4) file on the output volumes. Provides a means for distinguishing between production copies of a version if more than one is in use at a time. If PSTAMP is not defined, the default is used. The default consists of the UNIX system machine name followed by the string """"YYMMDDHHmm"""" (year, month, date, hour, minutes). |
| INTONLY | Indicates that the package should be installed interactively only when set to any non-NULL value. |
| PREDEPEND | Used to maintain compatibility with dependency checking on packages delivered earlier than System V Release 4. Pre-Release 4 dependency checks were based on whether or not the name file for the required package existed in the <i>/usr/options</i> directory. This directory is not maintained for Release 4 and later packages because the depend file is used for checking dependencies. However, entries can be created in this directory to maintain compatibility. This is done automatically by pkgmk . This field is to be assigned the package instance name of the package. |
| SERIALNUM | A serial number, if any, that uniquely identifies this copy of the package (maximum length of 256 ASCII characters). |
| ACTKEY | Activation key indicator. Set to YES indicates that an activation key is required to install the package. |
| PRODUCTNAME | A list of the products to which each package belongs. The format of this variable is: PRODUCTNAME=" <product>[<product> . . .] " |

Developers can define their own installation parameters by adding a definition to this file. A developer-defined parameter should begin with a capital letter.

Restrictions placed on a package installation by certain variables in the **pkginfo** file can be overridden by instructions in the **admin** file. For example, the restriction of allowable run states set by the **ISTATES** variable can be overridden by having

```
runlevel=nocheck
```

in the **admin** file being used for installation. (Default is "default".) See the **admin** file for further information.

Examples

Here is a sample **pkginfo** file:

```
PKG="oam"
NAME="OAM Installation Utilities"
VERSION="3"
VENDOR="AT&T"
HOTLINE="1-800-ATT-BUGS"
EMAIL="attunix!olsen"
VSTOCK="0122c3f5566"
CATEGORY="system.essential"
ISTATES="S 2"
RSTATES="S 2"
```

"**admin** File" on page 5

"**setinfo** File" on page 311

pkgmap File

Purpose

Describes the format of a package contents description file.

Description

The **pkgmap** file is an ASCII file that provides a complete listing of the package contents. Each entry in **pkgmap** describes a single "deliverable object file." A deliverable object file includes shell scripts, executable objects, data files, and directories. The entry consists of several fields of information, each field separated by a space. The fields are described below and must appear in the order shown.

| Field | Description |
|-------------|--|
| <i>part</i> | A field designating the part number in which the object resides. A part is a collection of files, and is the atomic unit by which a package is processed. A developer can choose the criteria for grouping files into a part (for example, based on class). If no value is defined in this field, part 1 is assumed. |

| Field | Description |
|-----------------|---|
| <i>ftype</i> | A one-character field that indicates the file type. Valid values are: f a standard executable or data file e a file to be edited upon installation or removal v volatile file (one whose contents are expected to change) d directory x an exclusive directory l linked file p named pipe c character special device b block special device i installation script or information file s symbolic link |
| | Once a file has the file type attribute v , it will always be volatile. For example, if a file being installed already exists and has the file type attribute v , then even if the version of the file being installed is not specified as volatile, the file type attribute remains volatile. |
| <i>class</i> | The installation class to which the file belongs. This name must contain only alphanumeric characters and be no longer than 12 characters. It is not specified if the ftype is i (information file). |
| <i>pathname</i> | The pathname where the object resides on the target machine, such as <i>/usr/bin/mail</i> . Relative pathnames (those that do not begin with a slash) indicate that the file is relocatable. For linked files (ftype is either l or s), pathname must be in the form of <i>path1=path2</i> , with <i>path1</i> specifying the destination of the link and <i>path2</i> specifying the source of the link. For symbolically linked files, when <i>path2</i> is a relative pathname starting with <i>./</i> or <i>../</i> , <i>path2</i> is not considered relocatable. For example, if you enter a line such as <pre>s /foo/bar/etc/mount=.../usr/sbin/mount</pre> <i>path1</i> (<i>/foo/bar/etc/mount</i>) is a symbolic link to <i>../usr/sbin/mount</i> . <i>pathname</i> can contain variables which support relocation of the file. A "\$" parameter can be embedded in the pathname structure. \$BASEDIR can be used to identify the parent directories of the path hierarchy, making the entire package easily relocatable. Default values for parameter and BASEDIR must be supplied in the <i>pkginfo</i> file and can be overridden at installation. Special characters, such as an equal sign ("="), are included in pathnames by surrounding the entire pathname in single quotes (as in, for example, ' <i>/usr/lib/~-</i> '). The major device number. The field is only specified for block or character special devices. The minor device number. The field is only specified for block or character special devices. The octal mode of the file (for example, 0664). A question mark ("?") indicates that the mode is left unchanged, implying that the file already exists on the target machine. This field is not used for linked files, packaging information files or non-installable files. The owner of the file (for example, <i>bin</i> or <i>root</i>). The field is limited to 14 characters in length. A question mark ("?") indicates that the owner is left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or non-installable files. It is used optionally with a package information file. If used, it indicates with what owner an installation script is executed. The owner can be a variable specification in the form of [\$A-Z] and is resolved at installation time. The group to which the file belongs (for example, <i>bin</i> or <i>sys</i>). The field is limited to 14 characters in length. A question mark ("?") indicates that the group is left unchanged, implying that the file already exists on the target machine. This field is not used for linked files or non-installable files. It is used optionally with a package information file. If used, it indicates with what group an installation script is executed. Can be a variable assignment in the form of [\$A-Z] and is resolved at installation time. The actual size of the file in bytes. This field is not specified for named pipes, special devices, directories, or linked files. The checksum of the file contents. This field is not specified for named pipes, special devices, directories, or linked files. |

| Field | Description |
|----------------|--|
| <i>modtime</i> | The time of last modification. This field is not specified for named pipes, special devices, directories, or linked files. |

The following three optional fields must be used as a group. That is, all three must be specified if any is specified.

| Field | Description |
|------------------|---|
| <i>mac</i> | The Mandatory Access Control (MAC) Level Identifier (LID), an integer value that specifies a combination of a hierarchical classification and zero or more non-hierarchical categories. A question mark ("?") indicates that the mac field is to be left unchanged, implying that the file already exists on the target machine. This field can only be applied to a file on a sfs filesystem and is not used for linked files or packaging information files. Note: Mandatory Access Control is not supported in this release; this field is present for compatibility with earlier release only. A value of 0 should be used if you must specify this field. |
| <i>fixed</i> | A comma-separated list of valid mnemonic fixed privilege names as defined for the filepriv command. The string NULL is used in place of the comma-separated list when fixed privileges are not to be specified. A question mark ("?") indicates that the fixed field is to be left unchanged, implying that the file already exists on the target machine. If the fixed attribute is not supplied, then files are installed with no fixed privileges. This field is not used for linked files or packaging information files. Note: Fixed privileges have no effect in the current release. This capability is maintained solely for compatibility with earlier releases. |
| <i>inherited</i> | A comma-separated list of valid mnemonic inherited privilege names as defined for the filepriv command. The string NULL is used in place of the comma separated list when privilege is not to be specified. A question mark ("?") indicates that the inherited field is to be left unchanged, implying that the file already exists on the target machine. If the inherited attribute is not supplied, then files are installed with no inheritable privileges. This field is not used for linked files or packaging information files. Note: Inheritable privileges have no effect in the current release. This capability is maintained solely for compatibility with earlier releases. |

Each **pkgmap** must have one line that provides information about the number and maximum size (in 512-byte blocks) of parts that make up the package. This line is in the following format:

:number_of_parts maximum_part_size

Lines that begin with "##" are comment lines and are ignored.

When files are saved during installation before they are overwritten, they are normally just copied to a temporary pathname. However, for files whose mode includes execute permission (but which are not editable), the existing version is linked to a temporary pathname and the original file is removed. This allows processes which are executing during installation to be overwritten.

The **pkgmap** file can contain only one entry per unique pathname.

An exclusive directory type (*file*) type *x* specifies directories that are constrained to contain only files that appear in the installation software database (*/var/sadm/install/contents*). If there are other files in the directory, they are removed by **pkgchk -fx** as described on the manual page for the **pkgchk** command.

Variable specifications for the *owner* and *group* fields are defined in the **pkginfo** file. For example, *owner* could be **\$OWNER** in the **pkgmap** file; if **OWNER** is defined as *root* in the **pkginfo** file, **\$OWNER** gets the value *root* when the file is installed.

Examples

The following is an example **pkgmap** file.

```
:2 500
1 i pkginfo 237 1179 541296672

pkgchk command

policy.cfg File

Purpose

The **policy.cfg** file contains attributes that are used while creating certificates when creating users or adding certificates to the local LDAP repository.

Description

The **policy.cfg** file consists of four stanzas: **newuser**, **storage**, **crl** and **comm**. These stanzas modify the behavior of some system administration commands. The **mkuser** command uses the **newuser** stanza. The **certlink** command uses the **storage** stanza. The **certadd** and **certlink** command use the **comm** and **crl** stanzas.

Examples

```
*****
* Example policy.cfg file
*****
* newuser Stanza:
*
* cert      Specifies whether the mkuser command generates a certificate (new) or
*            not (get) by default.
* ca        Specifies the CA used by the mkuser command when generating
*            a certificate.
* version   Specifies the version number of the certificate to be created.
*            The value 3 is the only supported value.
* tag       Specifies the auth_cert tag value used by the mkuser command when
*            creating a user when cert = new.
* label     Specifies the private key label used by the mkuser command when
*            generating a certificate.
* keystore  Specifies the keystore URI used by the mkuser command when generating
*            a certificate.
* passwd    Specifies the keystore's password used by the mkuser command when
*            generating a certificate.
* domain    Specifies the domain part of the certificate's subject alternate name
*            email value used by the mkuser command when generating a
*            certificate.
* validity  Specifies the certificate's validity period value used by the mkuser
*            command when generating a certificate.
* algorithm Specifies the public key algorithm used by the mkuser command when
*            generating a certificate.
* keysize   Specifies the minimum encryption key size in bits used by the mkuser
*            command when generating a certificate.
```

```

* keyusage      Specifies the certificate's key usage value used by the mkuser
*
* subalturi    Specifies the certificate's subject alternate name URI value
*               used by the mkuser command when generating a certificate.
*
* storage Stanza:
*
*           command when generating a certificate.
* replicate   Specifies whether the certlink command saves a copy of the certificate
*               (yes) or just the link (no).
*
* crl Stanza
*
* check       Specifies whether the certadd and certlink commands should check the
*               CRL (yes) or not (no).
*
* comm Stanza
*
* timeout     Specifies the timeout period in seconds when requesting certificate
*               information using HTTP (e.g., retrieving CRLs).

newuser:
    cert = new
    ca = local
    passwd = pki
    version = "3"
    keysize = 1024
    keystore = test
    validity = 60

storage:
    replicate = no

crl:
    check = yes

comm:
    timeout = 10
* end of policy.cfg

```

portlog File

Purpose

Contains per-port unsuccessful login attempt information and port locks.

Description

The **/etc/security/portlog** file is an ASCII file that contains stanzas of per port unsuccessful login attempt information and port locks. Each stanza has a name followed by a : (colon) that defines the port name. Attributes are in the form **Attribute=Value**. Each attribute ends with a new line character and each stanza ends with an additional new line character.

The attributes in the stanzas are as follows:

| Attribute | Definition |
|---------------------------------|---|
| locktime | Defines the time the port was locked in seconds since the epoch (zero time, January 1, 1970). This value is a decimal integer string. |
| unsuccessful_login_times | Lists the times of unsuccessful login attempts in seconds since the epoch. The list contains decimal integer strings separated by commas. |

These attributes do not have default values. If a value is not specified, the attribute is ignored.

Security

Access Control: This file grants read access to the root user and members of the security group, and write access only to the root user. Access for other users and groups depends upon the security policy of the operating system.

Examples

A typical record looks like the following example for the **/dev/tty0** port:

```
/dev/tty0:  
    locktime = 723848478  
    unsuccessful_login_times =  
    723848430,723848450,723848478
```

Files

| Item | Description |
|--------------------------------|---|
| /etc/security/portlog | Specifies the path to the file. |
| /etc/security/login.cfg | Contains configuration information for login and user authentication. |

Security Administration

/etc/security/privcmds File

Purpose

Contains security attributes for privileged commands.

Description

The **/etc/security/privcmds** file is an ASCII stanza file that contains privileged commands and their security attributes. Each stanza in the **/etc/security/privcmds** file is identified by the full path name to the command, followed by a colon (:). Each stanza contains attributes in the *Attribute=Value* form. The path name must be the absolute path to the command and cannot contain symbolic link directories or be a

symbolic link to the command. Each *Attribute=Value* pair is ended by a newline character, and each stanza is ended by an additional newline character. For an example of a stanza, see “Examples” on page 226.

Changes made to the **privcmds** file do not impact security considerations until the entire privileged command database is sent to the Kernel Security Tables through the **setkst** command or until the system is rebooted.

Modifying and Listing Entries in the privcmds File

Do not directly edit the **/etc/security/privcmds** file. Use the following commands and subroutines to manipulate the privileged commands database:

setsecattr

Adds a command entry to, or changes a command entry in, the **/etc/security/privcmds** file.

lssecattr

Displays attributes and their values.

rmsecattr

Removes a command from the **privcmds** file.

To write programs that affect entries in the **/etc/security/privcmds** file, use one or more of the following subroutines:

- **getcmdattr**
- **getcmdattrs**
- **putcmdattr**
- **putcmdattrs**

Attributes

A stanza in this file contains one or more of the following security attributes:

| Item | Description |
|--------------------|--|
| accessauths | Specifies the access authorizations as a comma-separated list of authorization names. A user whose current session has one of the authorizations in the list is allowed to run the command. You can specify a maximum of 16 authorizations. This attribute also allows three special values: ALLOW_OWNER Allows the Role Based Access Control (RBAC) framework to be used for the command owner. If the accessauths attribute is specified, when the command owner runs the command, the RBAC framework governs the privileges assigned to the process. If the accessauths attribute is not specified or the user running the command does not have an authorization in the accessauths attribute, DAC controls the execution and the RBAC framework grants no additional privileges. ALLOW_GROUP Allows the RBAC framework to be used for the group. If the accessauths attribute is specified, when the group runs the command, the RBAC framework governs the privileges assigned to the process. If the accessauths attribute is not specified or the user running the command does not have an authorization in the accessauths attribute, DAC controls the execution and the RBAC framework grants no additional privileges. ALLOW_ALL Allows the RBAC framework to be used for everyone. If the accessauths attribute is specified, when anyone runs the command, the RBAC framework governs the privileges assigned to the process. If the accessauths attribute is not specified or the user running the command does not have an authorization in the accessauths attribute, DAC controls the execution and the RBAC framework grants no additional privileges. |

| Item | Description |
|---------------------|---|
| authprivs | Specifies the authorized privileges that are assigned to the process on a specific authorization basis. The user running the command must gain access to the command through the accessauths attribute to enable the authprivs attribute. For each authorization in the list that is processed, the associated set of privileges is granted. The maximum number of authorization and privileges pairs is 16. The authorization and its corresponding privileges are separated by an equal sign (=), individual privileges are separated by a plus sign (+), and the authorization and privileges pairs are separated by a comma, as shown in the following line: auth=priv+priv...,auth=priv+priv...,... |
| | This attribute also supports three special authorization values: ALLOW_OWNER , ALLOW_GROUP , and ALLOW_ALL , to specify the additional privileges granted to the command owner, group or everyone, respectively. |
| authroles | The role or list of roles. Users having these have to be authenticated to allow execution of the command. A maximum of sixteen roles can be specified. |
| msgset | Specifies the file name of the message catalog that contains the one-line description of the authorization. The value is a character string. |
| innateprivs | Specifies a comma-separated list of privileges assigned to the process during the running of the command. The specified privileges are assigned to the process only if the command invocation is authorized through the access authorizations. |
| inheritprivs | Specifies a comma-separated list of privileges that is passed to child processes. |
| euid | Specifies the effective user ID to assume during the running of the command. |
| egid | Specifies the effective group ID to assume during the running of the command. |
| ruid | Specifies the real user ID to assume during the running of the command. |
| secflags | Specifies a comma-separated list of file security flags. The following value is valid: FSF_EPS Loads the process maximum privilege set into the effective privilege set upon execution. |

Security

The root user and the security group own this file. Read and write access is granted to the root user. Access for other users and groups depends on the security policy for the system.

Examples

The following example for a *Command* displays a typical stanza in the file:

```
/usr/bin/myprog:
    accessauths = aix.security.user.create,aix.security.user.change
    authprivs = aix.ras.audit=PV_AU_ADMIN
    innateprivs = PV_DAC_R,PV_DAC_W
    secflags = FSF_EPS
```

This entry indicates that the user running this command must be in a role session that has one of the authorizations listed in the **accessauths** attribute to run the command. If this condition is true, the privileges listed in the **innateprivs** attribute are granted to the resulting process. Also, if the user running this command has one of the privileged authorizations listed in the **authprivs** attribute, the process is granted the additional associated privileges.

rmsecattr command

Role Based Access Control (RBAC)

/etc/security/privdevs File

Purpose

Contains security attributes for privileged devices.

Description

The **/etc/security/privdevs** file is an ASCII stanza file that contains privileged devices and their security attributes. Each stanza in the **/etc/security/privdevs** file is identified by the full path name to the device, followed by a colon (:). Each stanza contains attributes in the *Attribute=Value* form. The path name must be the absolute path to the device and cannot contain symbolic link directories or be a symbolic link to the device. Each *Attribute=Value* pair is ended by a newline character, and each stanza is ended by an additional newline character. For an example of a stanza, see “Examples” on page 228.

Changes made to the **privdevs** file do not impact security considerations until the entire privileged device database is sent to the Kernel Security Tables through the **setkst** command or until the system is rebooted.

Modifying and Listing Entries in the devices File

Do not directly edit the **/etc/security/privdevs** file. Use the following commands and subroutines to manipulate the privileged devices database:

setsecattr

Adds a device entry to, or changes a device entry in, the **/etc/security/privdevs** file.

lssecattr

Displays attributes and their values.

rmsecattr

Removes a command from the devices file.

To write programs that affect entries in the **/etc/security/privdevs** file, use one or more of the following subroutines:

- **getdevattr**
- **getdevattrs**
- **putdevattr**
- **putdevattrs**

Attributes

A stanza in this file contains one or more of the following security attributes:

| Attribute | Description |
|-------------------|---|
| readprivs | Specifies the privileges required to read from the device as a comma-separated list of privilege names. You can define a maximum of eight privileges. A process with any of the specified read privileges can read from the device. |
| writeprivs | Specifies the privileges required to write to the device as a comma-separated list of privilege names. You can define a maximum of eight privileges. A process with any of the specified write privileges can write to the device. |

Security

The root user and the security group own this file. Read and write access is granted to the root user. Access for other users and groups depends on the security policy for the system.

Examples

The following example for a *Device* displays a typical stanza in the file:

```
/dev/mydev:  
    readprivs = PV_DAC_R,PV_AU_READ  
    writeprivs = PV_DAC_W,PV_AU_WRITE
```

This entry indicates that the process must have either the PV_DAC_R privilege or the PV_AU_READ privilege to read from the device. The process also must have either the PV_DAC_W privilege or the PV_AU_WRITE privilege to write to the device.

Role Based Access Control (RBAC)

/etc/security/privfiles File

Purpose

Contains the security attributes for privileged files.

Description

The **/etc/security/privfiles** file is an ASCII stanza file that contains privileged files and their security attributes. Each stanza in the **/etc/security/privfiles** file is identified by the full path name to the file, followed by a colon (:). Each stanza contains attributes in the *Attribute=Value* form. The path name must be the absolute path to the file and cannot contain symbolic link directories or be a symbolic link to the file. Each *Attribute=Value* pair is ended by a newline character, and each stanza is ended by an additional newline character. For an example of a stanza, see “Examples” on page 229.

Modifying and Listing Entries in the privfiles File

Do not edit the **/etc/security/privfiles** file directly. Instead, use commands and subroutines that are defined for managing privileged file databases. You can use the following commands to modify and list entries in the **privfiles** file:

setsecattr

Adds or changes a file entry in the **/etc/security/privfiles** file.

lssecattr

Display the attributes and their values.

rmsecattr

Remove a file from the **privfiles** file.

To write programs that affect entries in the **/etc/security/privfiles** file, use one or more of the following subroutines:

- **getpfileattr**
- **getpfileattrs**
- **putpfileattr**
- **putpfileattrs**

Attributes

A stanza in this file can contain one or more of the following security attributes:

| Attribute | Description |
|-------------------|---|
| readauths | Specifies the authorizations required to read from the file as a comma-separated list of authorization names. A user with any of the authorizations can use the /usr/bin/pvi command to read from the privileged file. |
| writeauths | Specifies the authorizations required to write to the file as a comma-separated list of authorization names. A user with any of the authorizations can use the /usr/bin/pvi command to write to the privileged file. |

Security

Read and write access is granted to the root user, and read access is granted to members of the security group. Access for other users and groups depends on the security policy for the system.

Examples

The following example for a *File* displays a typical stanza in the file:

```
/etc/myconf:  
    readauths = aix.security.role.list  
    writeauths = aix.security.role.change
```

This entry indicates that users with the `aix.security.role.list` authorization can use the **pvi** command to read the `/etc/myconf` file. Users with the `aix.security.role.change` authorization can use the **pvi** command to write to the `/etc/myconf` file.

/proc File

Purpose

Contains state information about processes and threads in the system.

Syntax

```
#include <sys/procfs.h>
```

Description

The `/proc` file system provides access to the state of each active process and thread in the system. The name of each entry in the `/proc` file system is a decimal number corresponding to the process ID. These entries are subdirectories and the owner of each is determined by the user ID of the process. Access to the process state is provided by additional files contained within each subdirectory. Except where otherwise specified, the term `/proc file` is meant to refer to a non-directory file within the hierarchy rooted at `/proc`. The owner of each file is determined by the user ID of the process.

The various `/proc` directory, file, and field names contain the term *lwp* (light weight process). This term refers to a kernel thread. The `/proc` files do not refer to user space pthreads. While the operating system does not use the term *lwp* to describe its threads, it is used in the `/proc` file system for compatibility with other UNIX operating systems.

The following standard subroutine interfaces are used to access the **/proc** files:

- **open** subroutine
- **close** subroutine
- **read** subroutine
- **write** subroutine

Most files describe process state and are intended to be read-only. The **ctl** (control) and **lwpctl** (thread control) files permit manipulation of process state and can only be opened for writing. The **as** (address space) file contains the image of the running process and can be opened for both reading and writing. A write open allows process control while a read-only open allows inspection but not process control. Thus, a process is described as open for reading or writing if any of its associated **/proc** files is opened for reading or writing, respectively.

In general, more than one process can open the same **/proc** file at the same time. Exclusive open is intended to allow process control without another process attempting to open the file at the same time. A process can obtain exclusive control of a target process if it successfully opens any **/proc** file in the target process for writing (the **as** or **ctl** files, or the **lwpctl** file of any kernel thread) while specifying the **O_EXCL** flag in the **open** subroutine. Such a call of the **open** subroutine fails if the target process is already open for writing (that is, if a **ctl**, **as**, or **lwpctl** file is open for writing). Multiple concurrent read-only instances of the **open** subroutine can exist; the **O_EXCL** flag is ignored on the **open** subroutine for reading. The first open for writing by a controlling process should use the **O_EXCL** flag. Multiple processes trying to control the same target process usually results in errors.

Data may be transferred from or to any locations in the address space of the traced process by calling the **lseek** subroutine to position the **as** file at the virtual address of interest, followed by a call to the **read** or **write** subroutine. An I/O request extending into an unmapped area is truncated at the boundary. A **read** or **write** request beginning at an unmapped virtual address fails with **errno** set to **EFAULT**.

Information and control operations are provided through additional files. The **<sys/procfs.h>** file contains definitions of data structures and message formats used with these files. Some of these definitions use sets of flags. The set types **pr_sigset_t**, **fltset_t**, and **sysset_t** correspond to signal, fault, and system call enumerations, respectively. These enumerations are defined in the **<sys/procfs.h>** files. The **pr_sigset_t** and **fltset_t** types are large enough to hold flags for its own enumeration. Although they are of different sizes, they have a common structure and can be manipulated by the following macros:

```
prfillset(&set);           /* turn on all flags in set */
premptyset(&set);          /* turn off all flags in set */
praddset(&set, flag);       /* turn on the specified flag */
prdelset(&set, flag);       /* turn off the specified flag */
r = prismember(&set, flag); /* != 0 if flag is turned on */
```

Either the **prfillset** or **premptyset** macro must be used to initialize the **pr_sigset_t** or **fltset_t** type before it is used in any other operation. The **flag** parameter must be a member of the enumeration that corresponds to the appropriate set.

The **sysset_t** set type has a different format, set of macros, and a variable length structure to accommodate the varying number of available system calls. You can determine the total number of system calls, their names, and number of each individual call by reading the **sySENT** file. You can then allocate memory for the appropriately sized **sysset_t** structure, by ensuring that the **pr_sysset** array needs an element for every 64 system call numbers, initialize its **pr_size** field, and then use the following macros to manipulate the system call set:

```
int      num;             /* Specifies the systemcall's number from sySENT */
uint64_t sysnum;          /* Specifies the number of elements in pr_set array */
uint64_t syssize;          /* Allocates the size */
sysset_t *set;            /* Specifies the pointer to sysset_t */
sysnum = (num - 1)/64 + 1;
syssize = (sysnum + 1) * sizeof(uint64_t);
```

```

set = (sysset_t *)malloc(sysssize);
set->pr_size = sysnum;
prfillsyssel(set)          /* set all syscalls in the sysset */
premptsyssel(set)          /* clear all syscalls in the sysset */
praddsyssel(set, num)      /* set specified syscall in the sysset */
prdelsyssel(set, num)      /* clear specified syscall in the sysset */
prissyssetmember(set, num) /* !=0 if specified syscall is set */

```

See the description of the **sysent** file for more information about system calls.

Every active process contains at least one kernel thread. Every kernel thread represents a flow of execution that is independently scheduled by the operating system. All kernel threads in a process share address space as well as many other attributes. Using the **ctl** and **Iwpctl** files, you can manipulate individual kernel threads in a process or manipulate all of them at once, depending on the operation.

When a process has more than one kernel thread, a representative thread is chosen by the system for certain process status file and control operations. The representative thread is stopped only if all the process's threads are stopped. The representative thread may be stopped on an *event of interest* only if all threads are stopped, or it may be stopped by a **PR_REQUESTED** stop only if no other events of interest exist.

The representative thread remains fixed as long as all the threads are stopped on events of interest or are in **PR_SUSPENDED** stop and the **PCRUN** operand is not applied to any of them.

When applied to the process control file (**ctl**), every **/proc** control operation that affects a kernel thread uses the same algorithm to choose which kernel thread to act on. With synchronous stopping (see **PCSET**), this behavior enables an application to control a multiple thread process using only the process level status and control files. For more control, use the thread-specific **Iwpctl** files.

The **/proc** file system can be used by both 32-bit and 64-bit control processes to get information about both 32-bit and 64-bit target processes. The **/proc** files provide 64-bit enabled mode invariant files to all observers. The mode of the controlling process does not affect the format of the **/proc** data. Data is returned in the same format to both 32-bit and 64-bit control processes. Addresses and applicable length and offset fields in the **/proc** files are 8 bytes long.

Directory Structure

At the top level, the **/proc** directory contains entries, each of which names an existing process in the system. The names of entries in this directory are process ID (pid) numbers. These entries are directories. Except where otherwise noted, the files described below are read-only. In addition, if a process becomes a *zombie* (one that has been terminated by its parent with an **exit** call but has not been suspended by a **wait** call), most of its associated **/proc** files disappear from the directory structure. Normally, later attempts to open or to read or write to files that are opened before the process is terminated elicit the **ENOENT** message. Exceptions are noted.

The **/proc** files contain data that presents the state of processes and threads in the system. This state is constantly changing while the system is operating. To lessen the load on system performance caused by reading **/proc** files, the **/proc** file system does not stop system activity while gathering the data for those files. A single read of a **/proc** file generally returns a coherent and fairly accurate representation of process or thread state. However, because the state changes as the process or thread runs, multiple reads of **/proc** files may return representations that show different data and therefore appear to be inconsistent with each other.

An *atomic* representation is a representation of the process or thread at a single and discrete point in time. If you want an atomic snapshot of process or thread state, stop the process and thread before reading the state. There is no guarantee that the data is an atomic snapshot for successive reads of **/proc** files for a running process. In addition, a representation is not guaranteed to be atomic for any I/O applied to the

as (address space) file. The contents of any process address space might be simultaneously modified by a thread of that process or any other process in the system.

Note: Multiple structure definitions are used to describe the **/proc** files. A **/proc** file may contain additional information other than the definitions presented here. In future releases of the operating system, these structures may grow by the addition of fields at the end of the structures.

The **/proc/pid** File Structure

The **/proc/pid** directory contains (but is not limited to) the following entries:

- as** Contains the address space image of the process. The **as** file can be opened for both reading and writing. The **Iseek** subroutine is used to position the file at the virtual address of interest. Afterwards, you can view and modify the address space with the **read** and **write** subroutines, respectively.
- ctl** A write-only file to which structured messages are written directing the system to change some aspect of the process's state or control its behavior in some way. The seek offset is not relevant when writing to this file, see types of control messages for more information. Individual threads also have associated **lwpctl** files. A control message may be written either to the **ctl** file of the process or to a specific **lwpctl** file with operation-specific effects as described. The effect of a control message is immediately reflected in the state of the process visible through appropriate status and information files.
- status** Contains state information about the process and one of its representative thread. The file is formatted as a **struct pstatus** type containing the following members:

```
uint32_t pr_flag;                      /* process flags from proc struct p_flag */  
uint32_t pr_flag2;                     /* process flags from proc struct p_flag2 */  
uint32_t pr_flags;                     /* /proc flags */  
uint32_t pr_nlwp;                     /* number of threads in the process */  
char    pr_stat;                      /* process state from proc p_stat */  
char    pr_dmodel;                    /* data model for the process */  
char    pr_pad1[6];                   /* reserved for future use */  
pr_sigset_t pr_sigpend;                /* set of process pending signals */  
prptr64_t pr_brkbase;                 /* address of the process heap */  
uint64_t pr_brksize;                  /* size of the process heap, in bytes */  
prptr64_t pr_stkbase;                 /* address of the process stack */  
uint64_t pr_stksize;                  /* size of the process stack, in bytes */  
pid64_t  pr_pid;                     /* process id */  
pid64_t  pr_ppid;                    /* parent process id */  
pid64_t  pr_pgid;                    /* process group id */  
pid64_t  pr_sid;                     /* session id */  
struct pr_timestruc64_t pr_utime;     /* process user cpu time */  
struct pr_timestruc64_t pr_stime;      /* process system cpu time */  
struct pr_timestruc64_t pr_cutime;     /* sum of children's user times */  
struct pr_timestruc64_t pr_cstime;     /* sum of children's system times */  
pr_sigset_t pr_sigtrace;              /* mask of traced signals */  
fltset_t  pr_flttrace;                /* mask of traced hardware faults */  
uint32_t  pr_sysentry_offset;         /* offset into pstatus file of sysset_t  
* identifying system calls traced on  
* entry. If 0, then no entry syscalls  
* are being traced. */  
uint32_t  pr_sysexit_offset;          /* offset into pstatus file of sysset_t  
* identifying system calls traced on  
* exit. If 0, then no exit syscalls  
* are being traced. */  
uint32_t  pr_pad[8];                  /* reserved for future use */  
lwpstatus_t pr_lwp;                  /* "representative" thread status */
```

The members of the **status** file are described below:

pr_flags

Specifies a bit-mask holding these flags:

PR_ISSYS

Process is a kernel process (see **PCSTOP**)

PR_FORK

Process has its inherit-on-fork flag set (see **PCSET**)

PR_RLC

Process has its run-on-last-close flag set (see **PCSET**)

PR_KLC

Process has its kill-on-last-close flag set (see **PCSET**)

PR_ASYNC

Process has its asynchronous-stop flag set (see **PCSET**)

PR_PTRACE

Process is controlled by the **ptrace** subroutine

pr_nlwp

Specifies the total number of threads in the process

pr_brkbase

Specifies the virtual address of the process heap

pr_brksize

Specifies the size, in bytes, of the process heap

Note: The address formed by the sum of the **pr_brkbase** and **pr_brksize** is the process **break** (see the **brk** subroutine).

pr_stkbase

Specifies the virtual address of the process stack

pr_stksize

Specifies the size, in bytes, of the process stack

Note: Each thread runs on a separate stack. The operating system grows the process stack as necessary.

pr_pid

Specifies the process ID

pr_ppid

Specifies the parent process ID

pr_pgid

Specifies the process group ID

pr_sid Specifies the session ID of the process**pr_utime**

Specifies the user CPU time consumed by the process

pr_stime

Specifies the system CPU process time consumed by the process

pr_cutime

Specifies the cumulative user CPU time consumed by the children of the process, expressed in seconds and nanoseconds

pr_cstime

Specifies the cumulative system CPU time, in seconds and nanoseconds, consumed by the process's children

pr_sigtrace

Specifies the set of signals that are being traced (see the **PCSTRACE** signal)

pr_flttrace

Specifies the set of hardware faults that are being traced (see the **PCSFAULT** signal)

pr_sysetry_offset

If non-zero, contains offsets into the *status* file to the **sysset_t** sets of system calls being traced on system call entry (see the **PCSENTRY** signal). This flag is zero if system call tracing is not active for the process.

pr_sysexit_offset

If non-zero, contains offsets into the *status* file to the **sysset_t** sets of system calls being traced on system call exit (see the **PCSEXIT** signal). This field is zero if system call tracing is not active for the process.

pr_lwp

If the process is not a zombie, contains an **lwpstatus_t** structure describing a representative thread. The contents of this structure have the same meaning as if it was read from a **lwpstatus** file.

psinfo Contains information about the process needed by the **ps** command. If the process contains more than one thread, a representative thread is used to derive the **lwpsinfo** information. The file is formatted as a **struct psinfo** type and contains the following members:

```
uint32_t pr_flag;           /* process flags from proc struct p_flag */
uint32_t pr_flag2;          /* process flags from proc struct p_flag2 */
uint32_t pr_nlwp;           /* number of threads in process */
uid_t   pr_uid;             /* real user id */
uid_t   pr_euid;            /* effective user id */
gid_t   pr_gid;             /* real group id */
gid_t   pr_egid;            /* effective group id */
uint32_t pr_argc;           /* initial argument count */
pid64_t pr_pid;             /* unique process id */
pid64_t pr_ppid;            /* process id of parent */
pid64_t pr_pgid;            /* pid of process group leader */
pid64_t pr_sid;             /* session id */
dev64_t  pr_ttydev;          /* controlling tty device */
prptr64_t pr_addr;           /* internal address of proc struct */
uint64_t pr_size;            /* size of process image in KB (1024) units */
uint64_t pr_rssize;           /* resident set size in KB (1024) units */
struct   pr_timestruc64_t pr_start; /* process start time, time since epoch */
struct   pr_timestruc64_t pr_time;  /* usr+sys cpu time for this process */
prptr64_t pr_argv;           /* address of initial argument vector in
                                user process */
prptr64_t pr_envp;           /* address of initial environment vector
                                in user process */
char     pr_fname[PRFNSZ];    /* last component of exec()ed pathname*/
char     pr_psargs[PRARGSZ];   /* initial characters of arg list */
uint64_t pr_pad[8];           /* reserved for future use */
struct   lwpsinfo pr_lwp;      /* "representative" thread info */
```

Note: Some of the entries in the **psinfo** file, such as **pr_flag**, **pr_flag2**, and **pr_addr**, refer to internal kernel data structures and might not retain their meanings across different versions of the operating system. They mean nothing to a program and are only useful for manual interpretation by a user aware of the implementation details.

The **psinfo** file is accessible after a process becomes a zombie.

The **pr_lwp** flag describes the representative thread chosen. If the process is a zombie, the **pr_nlwp** and **pr_lwp.pr_lwpid** flags are zero and the other fields of **pr_lwp** are undefined.

map Contains information about the virtual address map of the process. The file contains an array of **prmap** structures, each of which describes a contiguous virtual address region in the address space of the traced process.

Note: The **map** file may only contain entries for virtual address regions in the process that contain objects loaded into the process. This file may not contain array entries for other regions in the process such as the stack, heap, or shared memory segments.

The **prmap** structure contains the following members:

```
uint64_t pr_size;           /* size of mapping in bytes */
prptr64_t pr_vaddr;        /* virtual address base */
char     pr_mapname[PRMAPSZ]; /* name in /proc/pid/object */
uint64_t pr_off;           /* offset into mapped object, if any */
uint32_t pr_mflags;         /* protection and attribute flags */
uint32_t pr_pathoff;       /* if map entry is for a loaded object,
                           * offset into the map file to a
                           * null-terminated path name followed
                           * by a null-terminated member name.
                           * If file is not an archive file, the
                           * member name is null.
                           * The offset is 0 if map entry is
                           * not for a loaded object. */
```

The members are described below:

pr_vaddr

Specifies the virtual address of the mapping within the traced process

pr_size

Specifies the size of the mapping within the traced process

pr_mapname

If not an empty string, contains the name of a file that resides in the **object** directory and contains a file descriptor for the object to which the virtual address is mapped. The file is opened with the **open** subroutine.

pr_off Contains the offset within the mapped object (if any) to which the virtual address is mapped

pr_pathoff

If non-zero, contains an offset into the **map** file to the path name and archive member name of a loaded object

pr_mflags

Specifies a bit-mask of protection and the following attribute flags:

MA_MAINEXEC

Indicates that mapping applies to the main executable in the process

MA_READ

Indicates that mapping is readable by the traced process

MA_WRITE

Indicates that mapping is writable by the traced process

MA_EXEC

Indicates that mapping is executable by the traced process

MA_SHARED

Indicates that mapping changes are shared by the mapped object

A contiguous area of the address space having the same underlying mapped object may appear as multiple mappings because of varying read, write, execute, and shared attributes. The underlying mapped object does not change over the range of a single mapping. An I/O operation to a mapping marked **MA_SHARED** fails if applied at a virtual address not corresponding to a valid page in the underlying mapped object. Read and write operations to private mappings always succeed. Read and write operations to unmapped addresses always fail.

cred Contains a description of the credentials associated with the process. The file is formatted as a **struct prcred** type and contains the following members:

```
uid_t    pr_euid;           /* effective user id */
uid_t    pr_ruid;          /* real user id */
uid_t    pr_suid;          /* saved user id (from exec) */
gid_t    pr_egid;          /* effective group id */
gid_t    pr_rgid;          /* real group id */
gid_t    pr_sgids;         /* saved group id (from exec) */
uint32_t pr_ngroups;       /* number of supplementary groups */
gid_t    pr_groups[1];      /* array of supplementary groups */
```

sysent

Contains information about the system calls available to the process. The file can be used to find the number of a specific system call to trace. It can be used to find the name of a system call associated with a system call number returned in a **lwpstatus** file.

The file consists of a header section followed by an array of entries, each of which corresponds to a system call provided to the process. Each array entry contains the system call number and an offset into the **sysent** file to that system call's null-terminated name.

The **sysent** file is characterized by the following attributes:

- The system call names are the actual kernel name of the exported system call.
- The entries in the array do not have any specific ordering.
- There may be gaps in the system call numbers.
- Different processes may have different system call names and numbers, especially between a 32-bit process and a 64-bit process. Do not assume that the same names or numbers cross different processes.
- The set of system calls may change during while the operating system is running. You can add system calls while the operating system is running.
- The names and numbers of the system calls may change within different releases or when service is applied to the system.

cwd A link that provides access to the current working directory of the process. Any process can access the current working directory of the process through this link, provided it has the necessary permissions.

fd Contains files for all open file descriptors of the process. Each entry is a decimal number corresponding to an open file descriptor in the process. If an entry refers to a regular file, it can be opened with normal file semantics. To ensure that the controlling process cannot gain greater access, there are no file access modes other than its own read/write open modes in the controlled process. Directories will be displayed as links. An attempt to open any other type of entry will fail (hence it will display 0 permission when listed).

object

A directory containing read-only files with names as they appear in the entries of the **map** file, corresponding to objects mapped into the address space of the target process. Opening such a file yields a descriptor for the mapped file associated with a particular address-space region. The name **a.out** also appears in the directory as a synonym for the executable file associated with the text of the running process.

The object directory makes it possible for a controlling process to get access to the object file and any shared libraries (and consequently the symbol tables), without the process first obtaining the specific path names of those files.

root A link that provides access to the current root directory of the process. Any process can access the current root directory of the process through this link, provided that the process (that is attempting to access the root directory) has the necessary permissions.

mmap A file that contains an array of stat64x structures. Each structure describes information about a file that is associated with a memory-mapped area that is owned by the process.

- lwp** A directory containing entries each of which names a kernel thread within the containing process. The names of entries in this directory are thread ID (tid) numbers. These entries are directories containing additional files described below.

The /proc/pid/lwp/tid Structure

The directory **/proc/pid/lwp/tid** contains the following entries:

lwpctl

This is a write-only control file. The messages written to this file affect only the associated thread rather than the process as a whole (where appropriate).

lwpstatus

Contains thread-specific state information. This information is also present in the **status** file of the process for its representative thread. The file is formatted as a **struct lwpstatus** and contains the following members:

```
uint64_t pr_lwpid;           /* specific thread id */
uint32_t pr_flags;           /* thread status flags */
char pr_state;               /* thread state - from thread.h t_state */
uint16_t pr_cursig;          /* current signal */
uint16_t pr_why;              /* reason for stop (if stopped) */
uint16_t pr_what;             /* more detailed reason */
uint32_t pr_policy;           /* scheduling policy */
char pr_clname[PRCLSZ];      /* printable character representing pr_policy */
pr_sigset_t pr_lwppend;       /* set of signals pending to the thread */
pr_sigset_t pr_lwphold;       /* set of signals blocked by the thread */
pr_siginfo64_t pr_info;        /* info associated with signal or fault */
pr_stack64_t pr_altstack;     /* alternate signal stack info */
struct pr_sigaction64 pr_action; /* signal action for current signal */
uint16_t pr_syscall;          /* system call number (if in syscall) */
uint16_t pr_nsysarg;           /* number of arguments to this syscall */
uint64_t pr_sysarg[PRSYSARGS]; /* arguments to this syscall */
prgregset_t pr_reg;            /* general and special registers */
prfpregset_t pr_fpreg;         /* floating point registers */
pfamily_t pr_family;           /* hardware platform specific information */
```

The members of the **lwpstatus** file are described below:

pr_flags

Specifies a bit-mask holding these flags:

PR_STOPPED

Indicates that the thread is stopped

PR_ISTOP

Indicates that the thread is stopped on an event of interest (see the **PCSTOP** signal)

PR_DSTOP

Indicates that the thread has a stop directive in effect (see the **PCSTOP** signal)

PR_ASLEEP

Thread is in an interruptible sleep within a system call

PR_NOREGS

No register state was provided for the thread

pr_why and **pr_what**

Provides the reason for why a thread was stopped. The following are possible values of the **pr_why** member:

PR_REQUESTED

Shows that the thread was stopped in response to a stop directive, normally because the **PCSTOP** signal was applied or because another thread stopped on an

event of interest and the asynchronous-stop flag (see the **PCSET** signal) was not set for the process. The **pr_what** member is unused in this case.

PR_SIGNALLED

Shows that the thread stopped on receipt of a signal (see the **PCSTRACE** signal). The **pr_what** signal holds the signal number that caused the stop (for a newly-stopped thread, the same value is given with the **pr_cursig** member).

PR_FAULTED

Shows that the thread stopped upon incurring a hardware fault (see the **PCSFAULT** signal). The **pr_what** member contains the fault number that caused the stop.

PR_SYSENTRY

Shows a stop on entry to a system call (see the **PCSENTRY** signal). The **pr_what** member contains the system call number.

PR_SYSEXIT

Shows a stop on exit from a system call (see the **PCSExit** signal). The **pr_what** member contains the system call number.

PR_JOBCONTROL

Shows that the thread stopped because of the default action of a job control stop signal (see the **sigaction** subroutine). The **pr_what** member contains the stopping signal number.

pr_lwpid

Names the specific thread I/O

pr_cursig

Names the current signal, which is the next signal to be delivered to the thread. When the thread is stopped by the **PR_SIGNALLED** or **PR_FAULTED** signal, the **pr_info** member contains additional information pertinent to the particular signal or fault. The amount of data contained in the **pr_info** member depends on the stop type and whether or not the application specified the **SA_SIGINFO** flag when the signal handler was established. For **PR_FAULTED** stops and **PR_SIGNALLED** stops when the **SA_SIGINFO** flag was not specified, only the **si_signo**, **si_code**, and **si_addr** **pr_info** fields contain data. For **PR_SIGNALLED** stops when the **SA_SIGINFO** flag is specified, the other **pr_info** fields contain data as well.

pr_action

Contains the signal action information about the current signal. This member is undefined if the **pr_cursig** member is zero. See the **sigaction** subroutine.

pr_lwppend

Identifies any synchronously generated or thread-directed signals pending for the thread. It does not include signals pending at the process level.

pr_altstack

Contains the alternate signal stack information for the thread. See the **sigaltstack** subroutine.

pr_syscall

Specifies the number of the system call, if any, that is being executed by the thread. It is non-zero if and only if the thread is stopped on **PR_SYSENTRY** or **PR_SYSEXIT**.

If the **pr_syscall** member is non-zero, the **pr_nsysarg** member is the number of arguments to the system call and the **pr_sysarg** array contains the arguments. The **pr_nsysarg** member is always set to 8, the maximum number of system call parameters. The **pr_sysarg** member always contain eight arguments.

pr_clname

Contains the name of the scheduling class of the thread

pr_reg Structure containing the threads general and special registers. The size and field names of this structure are machine dependent. See the `<sys/m_proefs.h>` header file for description of this structure for your particular machine. The contents of this structure are undefined if the thread is not stopped.

pr_fpreg

Structure containing the threads floating point registers. The size and field names of this structure are machine dependent. The contents of this structure are undefined if the thread is not stopped.

pr_family

Contains the machine-specific information about the thread. Use of this field is not portable across different architectures. The **pr_family** structure contains extended context offset and size fields, which, if non-zero, indicate the availability of extended machine context information for the thread. A subsequent read of the **status** or **lwpstatus** file at the specified offset and size will retrieve the extended context information corresponding to a **prextset** structure. Alternatively, the entire **lwpstatus** file can be read and formatted as a **struct lwpstatusx**, which includes the **prextset** extension. The **pr_family** extended context offset and size members, if non-zero, indicate if the **prextset** member of the **lwpstatusx** structure is valid.

lwpsinfo

Contains information about the thread needed by the **ps** command. This information is also present in the **psinfo** file of the process for its representative thread if it has one. The file is formatted as a **struct lwpsinfo** type containing the following members:

```
uint64_t pr_lwpid;           /* thread id */  
prptr64_t pr_addr;          /* internal address of thread */  
prptr64_t pr_wchan;         /* wait addr for sleeping thread */  
uint32_t pr_flag;           /* thread flags */  
uchar_t pr_wtype;           /* type of thread wait */  
uchar_t pr_state;           /* numeric scheduling state */  
char pr_sname;              /* printable character representing pr_state */  
uchar_t pr_nice;             /* nice for cpu usage */  
int pr_pri;                 /* priority, high value = high priority*/  
uint32_t pr_policy;          /* scheduling policy */  
char pr_clname[PRCLSZ];      /* printable character representing pr_policy */  
cpu_t pr_onpro;              /* processor on which thread last ran */  
cpu_t pr_bindpro;            /* processor to which thread is bound */
```

Some of the entries in the **lwpsinfo** file, such as **pr_flag**, **pr_addr**, **pr_state**, **pr_wtype**, and **pr_wchan**, refer to internal kernel data structures and should not be expected to retain their meanings across different versions of the operating system. They have no meaning to a program and are only useful for manual interpretation by a user aware of the implementation details.

Control Messages

Process state changes are effected through messages written to the **ctl** file of the process or to the **lpctl** file of an individual thread. All control messages consist of an **int** operation code identifying the specific operation followed by additional data containing operands (if any). Multiple control messages can be combined in a single **write** subroutine to a control file, but no partial writes are permitted. Each control message (operation code plus operands) must be presented in its entirety to the **write** subroutine, not in pieces through several system calls.

The following are allowed control messages:

Note: Writing a message to a control file for a process or thread that has already exited elicits the error **ENOENT**.

PCSTOP, PCDSTOP, PCWSTOP

When applied to the process control file,

- **PCSTOP** directs all threads to stop and waits for them to stop;
- **PCDSTOP** directs all threads to stop without waiting for them to stop;
- **PCWSTOP** simply waits for all threads to stop.

When applied to a thread control file,

- **PCSTOP** directs the specific thread to stop and waits until it has stopped;
- **PCDSTOP** directs the specific thread to stop without waiting for it to stop;
- **PCWSTOP** simply waits for the thread to stop.

When applied to a thread control file, **PCSTOP** and **PCWSTOP** complete when the thread stops on an event of interest and immediately if the thread is already stopped.

When applied to the process control file, **PCSTOP** and **PCWSTOP** complete when every thread has stopped on an event of interest.

An *event of interest* is either a **PR_REQUESTED** stop or a stop that has been specified in the process's tracing flags (set by **PCSTRACE**, **PCSFAULT**, **PCSENTRY**, and **PCSEXIT**).

PR_JOBCONTROL and **PR_SUSPENDED** stops are not events of interest. (A thread may stop twice because of a stop signal; first showing **PR_SIGNALLED** if the signal is traced and again showing **PR_JOBCONTROL** if the thread is set running without clearing the signal.) If **PCSTOP** or **PCDSTOP** is applied to a thread that is stopped, but not because of an event of interest, the stop directive takes effect when the thread is restarted by the competing mechanism; at that time the thread enters a **PR_REQUESTED** stop before executing any user-level code.

A **write** operation of a control message that blocks is interruptible by a signal so that, for example, an **alarm** subroutine can be set to avoid waiting for a process or thread that may never stop on an event of interest. If **PCSTOP** is interrupted, the thread stop directives remain in effect even though the **write** subroutine returns an error.

A kernel process (indicated by the **PR_ISSYS** flag) is never executed at user level and cannot be stopped. It has no user-level address space visible through the **/proc** file system. Applying **PCSTOP**, **PCDSTOP**, or **PCWSTOP** to a system process or any of its threads elicits the error **EBUSY**.

PCRUN

Executes a thread again after it was stopped. The operand is a set of flags, contained in an **int** operand, describing optional additional actions.

The allowed flags for **PCRUN** are described below:

PRCSIG

Clears the current signal, if any. See **PCSSIG**.

PRCFAULT

Clears the current fault, if any. See **PCCFAULT**.

PRSTEP

Directs the thread to execute a single machine instruction. On completion of the instruction, a trace trap occurs. If **FLTTRACE** is being traced, the thread stops, otherwise it is sent **SIGTRAP**. If **SIGTRAP** is being traced and not held, the thread stops. When the thread stops on an event of interest the single-step directive is cancelled, even if the stop occurs before the instruction is executed.

PRSABORT

Instructs the thread to abort execution of the system call. See **PCSENTRY**, and **PCSEXIT**. It is significant only if the thread is in a **PR_SYSENTRY** stop or is marked **PR_ASLEEP**.

PRSTOP

Directs the thread to stop again as soon as possible after resuming execution. See

PCSTOP. In particular, if the thread is stopped on **PR_SIGNALLED** or **PR_FAULTED**, the next stop shows **PR_REQUESTED**, no other stop intervenes, and the thread does not execute any user-level code.

When applied to a thread control file, **PCRUN** makes the specific thread runnable. The operation fails and returns the error **EBUSY** if the specific thread is not stopped on an event of interest.

When applied to the process control file, a representative thread is chosen for the operation as described for the **/proc/pid/status** file. The operation fails and returns the error **EBUSY** if the representative thread is not stopped on an event of interest. If **PRSTEP** or **PRSTOP** were requested, **PCRUN** makes the representative thread runnable. Otherwise, the chosen thread is marked **PR_REQUESTED**. If as a result all threads are in the **PR_REQUESTED** stop state, they all become runnable.

Once **PCRUN** makes a thread runnable, it is no longer stopped on an event of interest, even if it remains stopped because of a competing mechanism.

PCSTRACE

Defines a set of signals to be traced in the process. Upon receipt of one of these signals, the thread stops. The set of signals is defined using an operand **pr_sigset_t** contained in the control message. Receipt of **SIGKILL** cannot be traced. If you specify **SIGKILL**, the thread ignores it.

If a signal that is included in a thread's held signal set is sent to that thread, the signal is not received and does not cause a stop until it is removed from the held signal set. Either the thread itself removes it or you remove it by setting the held signal set with **PCSHOLD** or the **PRSHOLD** option of **PCRUN**.

PCSSIG

Specifies the current signal and its associated signal information for the specific thread or representative thread. This information is set according with the operand **pr_siginfo64** structure. If the specified signal number is zero, the current signal is cleared. The error **EBUSY** is returned if the thread is not stopped on an event of interest.

The syntax of this operation are different from those of the **kill** subroutine, **pthread_kill** subroutine, or **PCKILL**. With **PCSSIG**, the signal is delivered to the thread immediately after execution is resumed (even if the signal is being held) and an additional **PR_SIGNALLED** stop does not intervene even if the signal is being traced. Setting the current signal to **SIGKILL** ends the process immediately.

PCKILL

If applied to the process control file, a signal is sent to the process with syntax identical to those of the **kill** subroutine. If applied to a thread control file, a signal is sent to the thread with syntax identical to those of the **pthread_kill** subroutine. The signal is named in an operand **int** contained in the message. Sending **SIGKILL** ends the process or thread immediately.

PCUNKILL

Specifies a signal to be removed from the set of pending signals. If applied to the process control file, the signal is deleted from the process's pending signals. If applied to a thread control file, the signal is deleted from the thread's pending signals. The current signal (if any) is unaffected. The signal is named in an operand **int** in the control message. An attempt to delete **SIGKILL** results in the error **EINVAL**.

PCSHOLD

Sets the set of held signals for the specific or representative thread according to the operand **sigset_t** structure. Held signals are those whose delivery is delayed if sent to the thread. **SIGKILL** or **SIGSTOP** cannot be held. If specified, they are silently ignored.

PCSFAULT

Defines a set of hardware faults to be traced in the process. When incurring one of these faults, a thread stops. The set is defined via the operand **fltset_t** structure. Fault names are defined in the **<sys/procfs.h>** file and include the following:

Note: Some of these may not occur on all processors; other processor-specific faults may exist in addition to those described here.

FLTILL

Illegal instruction

FLTPRIV

Privileged instruction

FLTBPTR

Breakpoint trap

FLTTRACE

Trace trap

FLTACCESS

Memory access fault (bus error)

FLTBOUNDS

Memory bounds violation

FLTIOVF

Integer overflow

FLTIZDIV

Integer zero divide

FLTFPE

Floating-point exception

FLTSTACK

Unrecoverable stack fault

When not traced, a fault normally results in the posting of a signal to the thread that incurred the fault. If a thread stops on a fault, the signal is posted to the thread when execution is resumed unless the fault is cleared by **PCCFAULT** or by the **PRCFAULT** option of **PCRUN**. The **pr_info** field in **/proc/pid/status** or in **/proc/pid/lwp/tid/lwpstatus** identifies the signal to be sent and contains machine-specific information about the fault.

PCCFAULT

Specifies the current fault, if any, to be cleared. The associated signal is not sent to the specified thread or representative thread.

PCSENTRY

Instructs the process's threads to stop on entry to specified system calls. The set of system calls to be traced is defined via an operand **sysset_t** structure. When entry to a system call is being traced, a thread stops after having begun the call to the system but before the system call arguments have been fetched from the thread.

If a thread is stopped on entry to a system call (**PR_SYSENTRY**) or when sleeping in an interruptible system call (**PR_ASLEEP** is set), it may be instructed to go directly to system call exit by specifying the **PRSABORT** flag in a **PCRUN** control message. Unless exit from the system call is being traced, the thread returns to user level showing error **EINTR**.

PCSEXIT

Instructs the process's threads to stop on exit from specified system calls. The set of system calls to be traced is defined via an operand **sysset_t** structure. When exit from a system call is being traced, a thread stops on completion of the system call just before checking for signals and returning to user level. At this point, all return values have been stored into the threads's registers.

PCSET, PCRESET, PCUNSET

PCSET sets one or more modes of operation for the traced process. PCRESET or PCUNSET resets these modes. The modes to be set or reset are specified by flags in an operand **int** in the control message:

PR_FORK (inherit-on-fork)

When set, the tracing flags of the process are inherited by the child of a **fork** or **vfork** subroutine. When reset, child processes start with all tracing flags cleared.

PR_RLC (run-on-last-close)

When set and the last writable **/proc** file descriptor referring to the traced process or any of its threads is closed, all the tracing flags of the process are cleared, any outstanding stop directives are cancelled, and if any threads are stopped on events of interest, they are set running as though **PCRUN** had been applied to them. When reset, the process's tracing flags are retained and threads are not set running on last close.

PR_KLC (kill-on-last-close)

When set and the last writable **/proc** file descriptor referring to the traced process or any of its threads is closed, the process is exited with **SIGKILL**.

PR_ASYNC (asynchronous-stop)

When set, a stop on an event of interest by one thread does not directly affect other threads in the process. When reset and a thread stops on an event of interest other than **PR_REQUESTED**, all other threads in the process are directed to stop.

The error **EINVAL** is returned if you specify flags other than those described above or to apply these operations to a system process. The current modes are reported in the **pr_flags** field of the **/proc/pid/status** file.

PCSREG

Sets the general and special registers for the specific or representative thread according to the operand **prgregset_t** structure. There may be machine-specific restrictions on the allowable set of changes. PCSREG fails and returns the error **EBUSY** if the thread is not stopped on an event of interest or is stopped in the kernel.

PCSFREG

Sets the floating point registers for the specific or representative thread according to the operand **fpregset_t** structure. The error **EINVAL** is returned if the system does not support floating-point operations (no floating-point hardware and the system does not emulate floating-point machine instructions). PCSFREG fails and returns the error **EBUSY** if the thread is not stopped on an event of interest or is stopped in the kernel.

PCSVREG

Sets the vector registers for the specific or representative thread according to the operand **prvregset_t** structure. The error **EINVAL** is returned if the system does not support vector operations (no vector hardware and the system does not emulate vector machine instructions), or if the representative thread has not referenced the vector unit. PCSVREG fails and returns the error **EBUSY** if the thread is not stopped on an event of interest or is stopped in the kernel.

PCNICE

The traced process's **nice** priority is incremented by the amount contained in the operand **int**. Only the superuser may better a process's priority in this way, but any user may make the priority worse. This operation is significant only when applied to a process in the time-sharing scheduling class.

Files

| Item | Description |
|--|--|
| /proc | Directory (list of processes) |
| /proc/ <i>pid</i> | Directory for the process <i>pid</i> |
| /proc/ <i>pid</i> /status | Status of process <i>pid</i> |
| /proc/ <i>pid</i> /ctl | Control file for process <i>pid</i> |
| /proc/ <i>pid</i> /psinfo | ps info for process <i>pid</i> |
| /proc/ <i>pid</i> /as | Address space of process <i>pid</i> |
| /proc/ <i>pid</i> /map | as map info for process <i>pid</i> |
| /proc/ <i>pid</i> /cred | Credentials information for process <i>pid</i> |
| /proc/ <i>pid</i> /object | Directory for objects for process <i>pid</i> |
| /proc/ <i>pid</i> /root | Link to the current root directory for process <i>pid</i> |
| /proc/ <i>pid</i> /mmap | Memory-mapped files information for process <i>pid</i> |
| /proc/ <i>pid</i> /sigact | Signal actions for process <i>pid</i> |
| /proc/ <i>pid</i> /sySENT | System call information for process <i>pid</i> |
| /proc/ <i>pid</i> /cwd | Link to the current working directory for process <i>pid</i> |
| /proc/ <i>pid</i> /fd | Directory for open file descriptors for process <i>pid</i> |
| /proc/ <i>pid</i> /lwp/ <i>tid</i> | Directory for thread <i>tid</i> |
| proc/ <i>pid</i> /lwp/ <i>tid</i> /lwpstatus | Status of thread <i>tid</i> |
| /proc/ <i>pid</i> /lwp/ <i>tid</i> /lwpcntl | Control file for thread <i>tid</i> |
| /proc/ <i>pid</i> /lwp/ <i>tid</i> /lwpinfo | ps info for thread <i>tid</i> |

Error Codes

Other errors can occur in addition to the errors normally associated with file system access:

| Error Code | Description |
|------------|--|
| ENOENT | The traced process or thread has exited after being opened. |
| EFAULT | A read or write request was begun at an invalid virtual address. |
| EIO | A write subroutine was attempted at an illegal address in the traced process. |
| EBUSY | This error is returned because of one of the following reasons: <ul style="list-style-type: none"> • PCSTOP, PCDSTOP or PCWSTOP was applied to a system process. • An exclusive open subroutine was attempted on a process file already open for writing. • PCRUN, PCSSIG, PCSREG or PCSFPREG was applied to a process or thread that was not stopped on an event of interest. • An attempt was made to mount the /proc file system when it is already mounted. |
| EPERM | Someone other than the privileged user attempted to better a process's priority by issuing PCNICE. |
| ENOSYS | An attempt was made to do an unsupported operation (such as create, remove, link, or unlink) on an entry in the /proc file system. |

| Error Code | Description |
|---------------|---|
| EINVAL | An invalid argument was supplied to a system call. The following are some—but not all—possible conditions that can elicit this error: |
| | <ul style="list-style-type: none"> • A control message operation code is undefined. • A control message is ill-formed. • The PRSTEP option of the PCRUN operation was used on an implementation that does not support single-stepping. • An out of range signal number was specified with PCSSIG, PCKILL, or PCUNKILL. • SIGKILL was specified with PCUNKILL. • PCSFPREG was applied on a machine without floating-point support. • PCSVREG was applied on a machine without vector support or was applied to a thread that has not referenced the vector unit. |
| EINTR | A signal was received by the controlling process while waiting for the traced process or thread to stop via PCSTOP or PCWSTOP . |
| EBADF | The traced process performed an exec subroutine on a setuid/setgid object file or on an object file that is not readable for the process. All further operations on the process or thread file descriptor (except the close subroutine) elicit this error. |

Security

The effect of a control message is guaranteed to be atomic with respect to the traced process.

For security reasons, except for the privileged user, an **open** subroutine of a **/proc** file fails unless both the effective user ID and effective group ID of the caller match those of the traced process and the process's object file is readable by the caller. Files corresponding to **setuid** and **setgid** processes can be opened only by the privileged user. Even if held by the privileged user, an open process or thread file descriptor becomes invalid if the traced process performs an **exec** subroutine on a setuid/setgid object file or on an object file that it cannot read. Any operation performed on an invalid file descriptor, except for the **close** subroutine, fails with **EBADF**. In this case, if any tracing flags are set and the process or any thread file is open for writing, the process is directed to stop and its run-on-last-close flag is set (see **PCSET**).

This feature enables a controlling process (that has the necessary permission) to reopen the process file to obtain new valid file descriptors, close the invalid file descriptors, and proceed. Just closing the invalid file descriptors causes the traced process to resume execution with no tracing flags set. Any process that is not currently open for writing with tracing flags left over from a previous **open** subroutine and that performs an **exec** subroutine on a setuid/setgid or unreadable object file is not stopped. However, that process does not have all its tracing flags cleared.

proxy.ldif.template File

Purpose

Defines the ACL that will be set for the proxy identity when the **mksecldap** command is invoked with the **-x** and **-X** command options.

Description

The **proxy.ldif.template** file contains LDAP data interchange formatted (LDIF) entries used by **mksecldap** when creating a proxy identity during server setup. By default, the file contains entries to create the proxy identity and password and set the default ACL to propagate down from the base DN (distinguished name).

Entries in the file may be modified or added by the system administrator to customize the LDAP server setup performed by the **mksecldap** command. Several case sensitive key words exist in the file that are dynamically replaced with the values that **mksecldap** is invoked with as described in the following table.

| Keyword | Substitution |
|-------------|--|
| {baseDN} | Replaced with base distinguished name specified by the -d option of the mksecldap command. |
| {proxyDN} | Replaced with proxy user distinguished name specified by the -x option of mksecldap . |
| {proxyUser} | Replaced with proxy user name (proxyDN stripped of suffix and prefix). |
| {proxyPWD} | Replaced with proxy user password specified by the -X option of mksecldap . |

mksecldap command

Lightweight Directory Access Protocol

prtglobalconfig File

Purpose

Configures global configurations for AIX printing subsystem.

Description

The **/etc/prtglobalconfig** file describes the global printing configurations available for use which a root user or a user with proper privileges can set.

This file stores the configuration which affects the AIX printing subsystem. Any authorized user can configure the settings pertaining to printing subsystem. Currently only one property of the printing subsystem can be set using this command. This file consists of **<name>=<value>** pair. The name is the setting and the value is the corresponding value for the setting. The following list shows the setting which can be set using this file.

1. ERRMSGCONTROL

This setting affects the global printer message. This setting can be used to select one of the following.

1. ALLON (All messages turned on).
2. LOGALL (All messages turned on, but logged to a log file). Currently not supported.
3. CRITON (Only the most critical error messages turned on). Currently this is the same as option 1.
4. ALLOFF (All messages turned off).

Examples

1. The file might contain the following to suppress all printer error messages:

```
ERRMSGCONTROL=ALLOFF
```

Note: Some messages generated by the printing subsystem cannot be ignored and are logged in the console log file.

Files

| Item | Description |
|----------------------|---|
| /etc/prtglobalconfig | Contains the global configuration file. |
| /etc/prtgbconfig | Contains the program which can be used to configure the global printer configuration. |
| /dev/null | Provides access to the null device. |
| /etc/qconfig | Contains the configuration file. |
| /etc/qconfig.bin | Contains the digested, binary version of the /etc/qconfig file. |

Printing administration

Print spooler

Printers and printing

pwdhist File

Purpose

Contains password history information.

Description

The **/etc/security/pwdhist.dir** and **/etc/security/pwdhist.pag** files are database files created and maintained by Database Manager (DBM) subroutines. The files maintain a list of previous user passwords.

The **pwdhist** files store information by user name. User names are the keys of the DBM subroutines. The password list contains multiple pairs of a **lastupdate** value and an encrypted, null-terminated password. This password list is a key's associated content and the **lastupdate** value is a 4-byte, unsigned long. The encrypted password is the size of the **PW_CRYPTLEN** value. Thus, an entry in the database file is of the following format:

```
lastupdatepasswordlastupdatepasswordlastupdatepassword...
d...
```

The password list is in descending chronological order, with the most recent password appearing first in the list.

To retrieve a user's password history, use the **dbm_fetch** subroutine. To delete a user's password history, use the **dbm_delete** subroutine.

Security

Access Control: The files grant read and write access only to the root user.

Examples

If user **sally** has the following previous passwords:

```
password = 6PugcayXL.1Rw ;
lastupdate = 737161212
password = r5MZvr69mGeLE ;
lastupdate = 746458629
```

the **dbm_fetch** subroutine returns the following entry for the key **sally**:

XXXXr5MZvr69mGeLEXXXX6PugcayXL.1Rw

where **XXXX** would be four bytes that can be copied into an unsigned long to get the last update time.

List of NDBM and DBM Programming References

publickey File for NIS

Purpose

Contains public or secret keys for maps.

Description

The **/etc/publickey** file is the public key file used for secure networking. Each entry in the file consists of a network user name (which may refer to either a user or a host name), followed by the user's public key (in hex notation), a colon, and then the user's secret key encrypted with its login password (also in hex notation). This file is part of the Network Support Facilities.

This file is altered either by the user through the **chkey** command or by the person who administers the system through the **newkey** command. The **publickey** file should only contain data on the master server, where it is converted into the **publickeybyname** NIS map.

Exporting a File System Using Secure NFS

/etc/security/pwdalg.cfg File

Purpose

Contains configuration information for loadable password algorithms (LPA).

Description

The **/etc/security/pwdalg.cfg** file is an ASCII file that contains stanzas of configuration information for loadable password algorithms (LPA). Each stanza has a name, followed by a colon (:), which defines an LPA. An LPA name is used in the **/etc/security/login.cfg** file to specify the default system-wide password algorithm. Attributes are in the form *Attribute=Value*. Each attribute ends with a newline character, and each stanza ends with an additional newline character. For an example of a stanza, see “Examples” on page 249.

| Attribute | Definition |
|--------------------|---|
| lpa_module | Defines the path of the LPA to load. If you do not specify a full path, the /usr/lib/security directory is prefixed for 32-bit. The full path of the 64-bit load module is the full path of the 32-bit module suffixed with _64 . |
| lpa_options | Specifies an optional attribute that provides a means to communicate run-time configuration options to the load module. The value is a comma-separated list of items. Options that can be used are specific to the LPA that you specify in the lpa_module attribute. The optional flags for each LPA module are described in the product documentation for that LPA. |

Security

Read and write access is granted to the root user and members of the security group.

Examples

The following example is a typical stanza:

```
*****
*
* /usr/lib/security/smd5 is a password hashing load module using
* the MD5 algorithm.
*
* It supports password length up to 255 characters.
*
* To generate smd5 password hash compatible to standard salted MD5,
* add the following option line for smd5 stanza.
*     lpa_options = std_hash=true
*
* Note: password hash generated with this option won't be compatible with
* hash generated without this option.
*
*****
smd5:
    lpa_module = /usr/lib/security/smd5

ssha256:
    lpa_module = /usr/lib/security/ssha
    lpa_options = algorithm=sha256,cost_num=9,salt_len=24
```

Files

| Item | Description |
|---------------------------------|---|
| /etc/security/pwdalg.cfg | Specifies the path to the file. |
| /etc/security/login.cfg | Contains configuration information for login and user authentication. |
| /etc/passwd | Contains the basic attributes of users. |
| /etc/security/passwd | Contains password information. |

Security

qconfig File

Purpose

Configures a printer queuing system.

Description

The **/etc/qconfig** file describes the queues and devices available for use by both the **enq** command, which places requests on a queue, and the **qdaemon** command, which removes requests from the queue and processes them. The **qconfig** file is an attribute file.

Some stanzas in this file describe queues, and other stanzas describe devices. Every queue stanza requires that one or more device stanzas immediately follow it in the file. The first queue stanza describes the default queue. Unless the **LPDEST** or **PRINTER** environment variable is set, the **enq** command uses this queue when it receives no queue parameter. If **LPDEST** contains a value, that value takes precedence over the **PRINTER** environment variable. Destination command-line options always override both variables.

The name of a queue stanza can be from 1 to 20 characters long. Some of the fields and their possible values that can appear in this file are:

| Field | Definition |
|---------------|--|
| acctfile | Identifies the file used to save print accounting information. FALSE , the default value, indicates suppress accounting. If the named file does not exist, no accounting is done. |
| device | Identifies the symbolic name that refers to the device stanza. |
| discipline | Defines the queue serving algorithm. The default value, fcfs , means first-come-first-served. sjn means shortest job next. |
| up | Defines the state of the queue. TRUE , the default value, indicates that the queue is running. FALSE indicates that it is not running. |
| recovery_type | Enables users to specify a recovery option when a print queue goes down. By default, the queue remains in the down state pending user intervention. |

Other options can be specified using the following values:

runscript <PathName>

A user-defined script is run when the queue goes down. The actions taken by the script are left to the discretion of the system administrator.

retry -T <delay> -R <retries>

The queue will stay down for the period of time specified in *delay* (expressed in minutes). Subsequently, it will be taken back up and the job will be retried. This is repeated up to the number of retries specified in *retries*. This is particularly useful in cases where job failures are due to temporary conditions likely to be resolved within the lapse of a certain time period (for example, a paper out condition or a temporary network glitch or slowdown).

sendmail <username>

The specified user will receive mail when the queue goes down notifying him or her that the specific printer is down.

Note: **lp** is a BSD standard reserved queue name and should not be used as a queue name in the **qconfig** file.

The following list shows some of the fields and their possible values that appear in the **qconfig** file for remote queues:

| Item | Description |
|--------------|--|
| host | Indicates the remote host where the remote queue is found. |
| s_statfilter | Specifies the short version filter used to translate remote queue status format. The following are possible values: /usr/lib/lpd/bsdshort BSD remote system |
| | /usr/lib/lpd/aixv2short RT remote system |
| | /usr/lib/lpd/atshort AT&T remote system |

| Item | Description |
|--------------|--|
| l_statfilter | Specifies the long version filter used to translate remote queue status format. The following are possible values: /usr/lib/lpd/bsdlong BSD remote system /usr/lib/lpd/aixv2long RT remote system /usr/lib/lpd/attlong AT&T remote system |
| rq | Specifies the remote queue name. In a remote print environment, the client configuration should specify the remote queue name or the server. Using the default remote queue name may cause unpredictable results. |

If a field is omitted, its default value is assumed. The default values for a queue stanza are:

```
discipline = fcfs
up         = TRUE
acctfile   = FALSE
recovery_type = queuedown
```

The device field cannot be omitted.

The name of a device stanza is arbitrary and can be from 1 to 20 characters long. The fields that can appear in the stanza are:

| Field | Definition |
|---------|---|
| access | Specifies the type of access the backend has to the file specified by the file field. The value of access is write if the backend has write access to the file or both if it has both read and write access. This field is ignored if the file field has the value FALSE. |
| align | Specifies whether the backend sends a form-feed control before starting the job if the printer was idle. The default value is TRUE. |
| backend | Specifies the full path name of the backend, optionally followed by the flags and parameters to be passed to it. The path names most commonly used are /usr/lib/lpd/piobe for local print and /usr/lib/lpd/rembak for remote print. |
| feed | Specifies either the number of separator pages to print when the device becomes idle or the value never , the default, which indicates that the backend is not to print separator pages. |
| file | Identifies the special file where the output of backend is to be redirected. FALSE, the default value, indicates no redirection and that the file name is /dev/null . In this case, the backend opens the output file. |
| header | Specifies whether a header page prints before each job or group of jobs. A value of never , the default value, indicates no header page at all. always means a header page before each job. group means a header before each group of jobs for the same user. In a remote print environment, the default action is to print a header page and not to print a trailer page. |
| trailer | Specifies whether a trailer page prints after each job or group of jobs. A value of never , the default, means no trailer page at all. always means a trailer page after each job. group means a trailer page after each group of jobs for the same user. In a remote print environment, the default action is to print a header page and not to print a trailer page. |

The **qdaemon** process places the information contained in the feed, header, trailer, and align fields into a status file that is sent to the backend. Backends that do not update the status file do not use the information it contains.

If a field is omitted, its default value is assumed. The backend field cannot be omitted. The default values in a device stanza are:

```
file    = FALSE
access  = write
feed    = never
header  = never
trailer = never
align   = TRUE
```

The **enq** command automatically converts the ASCII **qconfig** file to binary format when the binary version is missing or older than the ASCII version. The binary version is found in the **/etc/qconfig.bin** file.

Note: The **qconfig** file should not be edited while there are active jobs in any queue. Any time the **qconfig** file is changed, jobs submitted prior to the change will be processed before jobs submitted after the change.

Editing includes both manual editing and use of the **mkque**, **rmque**, **chque**, **mkquedev**, **rmquedev**, or **chquedev** command. It is recommended that all changes to the **qconfig** file be made using these commands. However, if manual editing is desired, first issue the **enq -G** command to bring the queuing system and the **qddaemon** to a halt after all jobs are processed. Then edit the **qconfig** file and restart the **qddaemon** with the new configuration.

Examples

1. The batch queue supplied with the system might contain these stanzas:

```
bsh:  
  discipline = fcfs  
  device = bshdev  
bshdev:  
  backend = /usr/bin/ksh
```

To run a shell procedure called **myproc** using this batch queue, enter:

```
qprt -Pbsh myproc
```

The queuing system runs the files one at a time, in the order submitted. The **qddaemon** process redirects standard input, standard output, and standard error to the **/dev/null** file.

2. To allow two batch jobs to run at once, enter:

```
bsh:  
  discipline = fcfs  
  device = bsh1,bsh2  
bsh1:  
  backend = /usr/bin/ksh  
bsh2:  
  backend = /usr/bin/ksh
```

3. To set up a remote queue, **bsh**, enter:

```
remh:  
  device = rd0  
  host = pluto  
  rq = bsh  
rd0:  
  backend = /usr/lib/lpd/rembak
```

4. To set a local queue such that mail is sent to **user1@xyz.com** when it goes down, enter:

```
ps:  
  recovery_type = sendmail user1@xyz.com  
  device = lp0  
lp0:  
  file = /dev/lp0  
  header = never  
  trailer = never  
  access = both  
  backend = /usr/lib/lpd/piobe
```

raspertune File

Purpose

Contains persistent RAS customization.

Description

You can use the `/var/adm/ras/raspertune` file to specify persistent RAS attribute values, which are used when the system is rebooted, if the `bosboot` command is run after the file is modified.

This file consists of a series of control commands: the `ctctrl` command, the `dumpctrl` command, and the `errctrl` command. Other commands are not allowed. You must use the `-p` flag in each command. Otherwise, the `bosboot` command ignores the control command. You can continue lines by ending them with a backslash (\) character. Use rules for the `/bin/sh` file to quote command line arguments.

The file is automatically modified when you use a control command with the `-P` flag. You can also modify the file manually, but only when IBM Service personnel requests it.

Files

| Item | Description |
|--------------------------------------|---------------------------------|
| <code>/var/adm/ras/raspertune</code> | Specifies the path to the file. |

Related information:

- `dumpctrl` command
- `errctrl` command

rc.boot File

Purpose

Controls the machine boot process.

Description

Attention: Executing the `rc.boot` script on a system that is already running may cause unpredictable results.

The **/sbin/rc.boot** file is a shell script that is called by the simple shell **init** and the standard **init** command to bring up a system. Depending upon the type of boot device, the **rc.boot** file configures devices and also calls the appropriate applications. Appropriate applications include:

- Booting from disk
- Varying on a root volume group
- Enabling file systems
- Calling the BOS installation programs or diagnostics

The **rc.boot** program is only called by an init process.

Files

| Item | Description |
|--------------------------|--------------------------------------|
| /etc/inittab | Controls the initialization process. |
| /usr/lib/boot/ssh | Calls the rc.boot file. |

Related information:

rc.tcpip File for TCP/IP

Purpose

Initializes daemons at each system restart.

Description

The **/etc/rc.tcpip** file is a shell script that, when executed, uses SRC commands to initialize selected daemons. The **rc.tcpip** shell script is automatically executed with each system restart. It can also be executed at any time from the command line.

Most of the daemons that can be initialized by the **rc.tcpip** file are specific to TCP/IP. These daemons are:

- **inetd** (started by default)
- **gated**
- **routed**
- **named**
- **timed**
- **rwhod**

Note: Running the **gated** and **routed** daemons at the same time on a host may cause unpredictable results.

There are also daemons specific to the base operating system or to other applications that can be started through the **rc.tcpip** file. These daemons are:

- **lpd**
- **portmap**
- **sendmail**
- **syslogd**

The **syslogd** daemon is started by default.

Examples

1. The following stanza starts the **syslogd** daemon:

```
#Start up syslog daemon (for err
or and event logging)
start /usr/sbin/syslogd "$src_running"
```
2. The following stanza starts the **lpd** daemon:

```
#Start up print daemon
start /usr/sbin/lpd "$src_running"
```
3. The following stanza starts the **routed** daemon, but not the **gated** daemon:

```
#Start up routing daemon (only s
tart ONE)
start /usr/sbin/routed "$src_running" -g
#start /usr/sbin/gated "$src_running"
```

Installation of TCP/IP

realm.map File

Purpose

Contains the NFS local realm-to-domain maps.

Description

The **/etc/nfs/realm.map** file contains the local NFS realm-to-domain mappings. These mappings are used by NFS V4 to convert Kerberos principals to UNIX credentials. The **/etc/nfs/realm.map** file may be modified using the **chnfsrtd** command. The format of the **/etc/nfs/realm.map** file has one Kerberos realm and its corresponding NFS domain per line. A Kerberos realm should only be specified once in the file.

Files

| Item | Description |
|---------------------------|----------------------------|
| /etc/nfs/realm.map | The realm.map file. |

remote.unknown File for BNU

Purpose

Logs access attempts by unknown remote systems.

Description

The **/usr/sbin/uucp/remote.unknown** file is a shell script. It is executed by the Basic Networking Utilities (BNU) program when a remote computer that is not listed in the local **/etc/uucp/Permissions** file attempts to communicate with that local system. The BNU program does not permit the unknown remote system to connect with the local system. Instead, the **remote.unknown** shell procedure appends an entry to the **/var/spool/uucp/.Admin/Foreign** file.

Modify the **remote.unknown** file to fit the needs of your site. For example, to allow unknown systems to contact your system, remove the execute permissions for the **remote.unknown** file. You can also modify the shell script to send mail to the BNU administrator or to recognize certain systems and reject others.

Note: Only someone with root user authority can edit the **remote.unknown** file, which is owned by the **uucp** program login ID.

Files

| Item | Description |
|--------------------------------|--|
| /usr/sbin/uucp/remote.unknown | Contains the remote.unknown shell script. |
| /etc/sbin/Permissions | Describes access permissions for remote systems. |
| /var/spool/uucp/.Admin/Foreign | Lists access attempts by unknown systems. |

Basic Networking Utilities

resource_data_input Information

Purpose

Provides information about using an input file for passing resource class and resource attribute names and values to the resource monitoring and control (RMC) command-line interface (CLI).

Description

You can specify the name of a resource data input file with the **-f** command-line flag to pass resource persistent attribute values to the RMC CLI when using the command line directly would be too cumbersome or too prone to typographical errors. The data in this file is used for defining resources or for changing the persistent attribute values of a resource or resource class. This file has no set location. It can be a temporary file or a permanent file, depending on requirements.

The **mkrsrc** and **chrsrc** commands read this file when they are issued with the **-f** flag. The **lsrsrcdef** and **lsactdef** commands generate a file with this format when issued with the **-i** flag.

PersistentResourceAttributes

Persistent attribute names and values for one or more resources for a specific resource class used to define a new resource or change attribute values for an existing resource. The persistent resource attributes are read in by the commands **mkrsrc** and **chrsrc**. These attributes are ignored if the input file is read by the **chrsrc** command that has been specified with the **-c** flag.

PersistentResourceClassAttributes

Persistent attribute names and values for a resource class used to change the attribute values of an existing resource class. The persistent resource class attributes are read in by the command **chrsrc** only when the **-c** flag is specified.

In general, a *resource_data_input* file is a flat text file with the following format. **Bold** words are literal. Text that precedes a single colon (:) is an arbitrary label and can be any alphanumeric text.

PersistentResourceAttributes::

```
# This is a comment
label:
  AttrName1 = value
  AttrName2 = value
  AttrName3 = value
another label:
  Name      = name
  NodeNumber = 1
::
```

PersistentResourceClassAttributes::

```
label:
  SomeSettableAttrName = value
  SomeOtherSettableAttrName = value
::
```

See the **Examples** section for more details.

Some notes about formatting follow:

- The keywords **PersistentResourceAttributes** and **PersistentResourceClassAttributes** are followed by a double colon (::).
- The order of the keyword stanzas is not significant in the file. For example, **PersistentResourceClassAttributes** could precede **PersistentResourceClass**. It does not affect the portion of the data that is read in by the calling CLI.
- Individual stanza headings (beneath the keywords) are followed by a single colon (:), for example: c175n05 resource info:
- White space at the beginning of lines is not significant. Tabs or spaces are suggested for readability.
- Any line with a pound sign (#) as the first printable character is a comment.
- Each entry on an individual line is separated by white space (spaces or tabs).
- Blank lines in the file are not significant and are suggested for readability.
- There is no limit to the number of resource attribute stanzas included in a particular **PersistentResourceAttributes** section.
- There is no limit to the number of resource class attribute stanzas included in a particular **PersistentResourceClassAttributes** section. Typically, there is only one instance of a resource class. In this case, only one stanza is expected.
- If only one resource attribute stanza is included in a particular **PersistentResourceAttributes** section, the *label*: line can be omitted.
- If only one resource class attribute stanza is included in a particular **PersistentResourceClassAttributes** section, the *label*: line can be omitted.
- Values that contain spaces must be enclosed in quotation marks.
- A double colon (::) indicates the end of a section. If a terminating double colon is not found, the next **Reserved Keyword** or **end of file** signals the end of a section.
- Double quotation marks included within a string that is surrounded by double quotation marks must be escaped. (\").

Note: Double quotation marks can be nested within single quotation marks.

These are examples:

- "Name == \"testing\""
- 'Name == "testing"'

This syntax is preferred if your string is a selection string and you are going to cut and paste to the command line.

- Single quotation marks included within a string that is surrounded by single quotation marks must be escaped. (\').

Note: Single quotation marks can be nested within double quotation marks.

These are examples:

- 'Isn\'t that true'
- "Isn't that true"

This syntax is preferred if you are going to cut and paste to the command line.

- The format you use to enter data in a *resource_data_input* file may not be the same format used on the command line. The shell you choose to run the commands in has its own rules with regard to quotation marks. Refer to the documentation for your shell for these rules, which determine how to enter data on the command line.

Examples

1. This sample **mkrsrc** command:

```
mkrsrc -f /tmp/my_resource_data_input_file IBM.Example
```

uses the sample input file **/tmp/my_resource_data_input_file** for the **IBM.Example** resource class. The contents of the input file look like this:

```
PersistentResourceAttributes::  
# Resource 1 - only set required attributes  
resource 1:  
    Name="c175n04"  
    NodeList = {1}  
# Resource 2 - setting both required and optional attributes  
# mkrsrc -e2 IBM.Example displays required and optional  
# persistent attributes  
resource 2:  
    Name="c175n05"  
    NodeList = {1}  
    Int32 = -99  
    Uint32 = 99  
    Int64 = -123456789123456789  
    Uint64 = 123456789123456789  
    Float32 = -9.89  
    Float64 = 123456789.123456789  
    String = "testing 123"  
    Binary = 0xaabbccddeeff  
    RH = "0x0000 0x0000 0x00000000 0x00000000 0x00000000 0x00000000"  
    SD = [hello,1,{2,4,6,8}]  
    Int32Array = {-4, -3, -2, -1, 0, 1, 2, 3, 4}  
    Int64Array = {-4,-3,-2,-1,0,1,2,3,4}  
    Uint32Array = {0,1,2,3,4,5,6}  
    Uint64Array = {0,1,2,3,4,5,6}  
    Float32Array = {-3.3, -2.2, -1.2, 0, 1, 2.2, 3.3}  
    Float64Array = {-3.3, -2.2, -1.2, 0, 1, 2.2, 3.3}  
    StringArray = {abc,"do re mi", 123}  
    BinaryArray = {"0x01", "0x02", "0x0304"}  
    RHArray = {"0x0000 0x0000 0x00000000 0x00000000 0x00000000 0x00000000",  
               "0xaaaa 0xaaaa 0xbbbbbbbb 0xcccccccc 0xddddddd 0xeeeeeeee"}  
    SDArray = {[hello,1,{0,1,2,3}], [hello2,2,{2,4,6,8}]}
```

2. This sample **chrsrc** command:

```
chrsrc -f /tmp/Example/ch_resources -s 'Name == "c175n05"' IBM.Example
```

uses the sample input file **/tmp/Example/ch_resources** to change the attribute values of existing **IBM.Example** resources. The contents of the input file look like this:

```
PersistentResourceAttributes::  
# Changing resources that match the selection string entered  
# when running chrsrc command.  
resource 1:  
    String      = "this is a string test"  
    Int32Array   = {10,-20,30,-40,50,-60}
```

rmccli Information

Purpose

Provides general information about resource monitoring and control (RMC) and related commands.

Description

Provides general information about RMC and related commands, including datatypes, terminology, and references to related information.

Command structure and use

The RMC commands may be grouped into categories representing the different operations that can be performed on resource classes and resources:

- Creating and removing resources: **mkrsrc**, **rmrsrc**
- Modifying resources: **chrsrc**, **refrsrc**
- Viewing definitions and data: **lsrsrc**, **lssrcdef**
- Viewing actions: **lsactdef**
- Running actions: **runact**

The RMC commands can be run directly from the command line or called by user-written scripts. In addition, the RMC commands are used as the basis for higher-level commands, such as the event response resource manager (ERRM) commands.

Data display information

The flags that control the display function for the RMC CLI routines, in order of precedence, are:

1. **-l** for long display. This is the default display format.

For example, the command:

```
lsrsrc -s 'Name == "c175n05"' IBM.Foo Name NodeList SD Binary RH Int32Array
```

produces output that looks like this:

Persistent Attributes for Resource: IBM.Foo

resource 1:

```
Name      = "c175n05"
NodeList  = {1}
SD        = ["testing 1 2 3",1,{0,1,2}]
Binary    = "0xaabbcc00 0xeeff"
RH        = "0x0000 0x0000 0x00000000 0x00000000 0x00000000 0x00000000"
Int32Array = {1,5,-10,1000000}
```

2. **-t** for tabular display.

For example, the command:

```
lsrsrc -s 'Name ?= "Page"' -t IBM.Condition Name EventExpression
```

produces output that looks like this:

Persistent Attributes for Resource: IBM.Condition

```
Name          EventExpression
"Page space out rate" "VMPgSpOutRate > 500"
"Page fault rate"   "VMPgFaultRate > 500"
"Page out rate"     "VMPgOutRate > 500"
"Page in rate"      "VMPgInRate > 500"
"Page space in rate" "VMPgSpInRate > 500"
```

3. **-x** for suppressing headers when printing.

4. **-d** for colon (:) delimited display.

For example, the command:

```
lsrsrc -xd -s 'Name == "c175n05"' IBM.Foo Name Int32 Uint32Array SD Binary
```

produces output that looks like this:

```
c175n05:-100:{}:[{"hel  lo1",1,{0,1,2}}]:"0xaabbcc00 0xeeff":
```

Note the use of the **-x** flag along with the **-d** flag.

5. **-D delimiter** for string-delimited display.

For example, the command:

```
lsrsrc -xD:: -s 'Name == "c175n05"' IBM.Foo Name Int32 Uint32Array SD Binary
```

produces output that looks like this:

```
c175n05:::-100:{}::["hel  lo1",1,{0,1,2}]::"0xaabbcc00 0xeeff"::
```

Note the use of the **-x** flag along with the **-D Delimiter** flag.

When output of any list command (**lsrc**, **lsrcdef**) is displayed in the tabular output format, the printing column width may be truncated. If more characters need to be displayed (as in the case of strings) use the **-l** flag to display the entire field.

Data input formatting

Binary data can be entered in the following formats:

- "0x##### 0x##### 0x####..."
- "0x##### #####..."
- 0x##### #####...

Be careful when you specify strings as input data:

- Strings that contain no white space or non-alphanumeric characters can be entered as input without enclosing quotation marks
- Strings that contain white space or other alphanumeric characters must be enclosed in quotation marks
- Strings that contain single quotation marks (') must be enclosed by double quotation marks ("), as shown in this example: "this is a string with 'single quotations marks'"

Selection strings must be enclosed in double quotation marks, unless the selection string itself contains double quotation marks, in which case the selection string must be enclosed in single quotation marks. For information on how to specify selection strings, see the *RSCT: Administration Guide*.

- Sample selection string input: "NodeNumber == 1"
- Selection string input where double quotation marks are part of the selection string: 'Name == "c175n05"'

Structured data (SD) types must be enclosed in square brackets: [hello,1,{2,4,6,8}]

When supplying structured data (SD) as command-line input to the RMC commands, enclose the SD in single quotation marks: SD='[hello,1,{2,4,6,8}]'

Arrays of any type must be enclosed in braces {}:

- Array of integers: {-4, -3, -2, -1, 0, 1, 2, 3, 4}
- Array of strings: {abc, "do re mi", 123}
- Array of structured data: {[hello,1,{0,1,2,3}], [hello2,2,{2,4,6,8}]}

Arrays of any type with more than one element must be enclosed in quotation marks. For example:

- mkrsrc IBM Foo Name=testing NodeList={1} Uint32Array='1,2,3'
- mkrsrc IBM Foo Name=testing NodeList='1' Uint32_array='1,2,3'

Arrays of strings and arrays of structured data must always be enclosed in quotation marks.

When supplying arrays of structured data or arrays containing strings enclosed in quotation marks as command-line input to the RMC commands, enclose the entire array in single quotation marks:

- Array of strings: mkrsrc IBM.Foo Name="c175n05" NodeList={1} StringArray='{"a string", "a different string"}'
- Array of structured data: mkrsrc IBM.Foo Name="c175n05" NodeList={1} SDArray='[[{"string 1", 1, {1,1}}, {"string 2", 2, {1,2,3}}]]'

For more examples, see the **resource_data_input** information file.

Data output formatting

String data is always displayed in either double or single quotation marks, as shown below:

- A description attribute that equals the string "This is a string that contains white space" is displayed using long format as:
Description = "This is a string that contains white space"
- A description attribute value that equals an empty string "" is displayed in long format as:
Description = ""
- A description attribute value that equals a string that contains a new-line character at the end of the string is displayed in long format as:
Description = "This string ends with a new-line character..."
- A selection string containing double quotation marks is displayed in long format as:
SelectionString = 'Name == "c175n05"'
- A name attribute value that equals the string "c175n05" is displayed in long format as:
Name = "c175n05"

Binary data is displayed as follows:

"0x##### 0x##### 0x##### 0x###..."

Naming conventions

The following variable names are used throughout the RMC command informations:

Variable

Description

attr The name of a resource class or a resource attribute

resource_class

The name of a resource class

Terminology

attribute

Attributes are either persistent or dynamic. A resource class is defined by a set of persistent and dynamic attributes. A resource is also defined by a set of persistent and dynamic attributes. Persistent attributes define the configuration of the resource class and resource. Dynamic attributes define a state or a performance-related aspect of the resource class and resource. In the same resource class or resource, a given attribute name can be specified as either persistent or dynamic, but not both.

resource

An entity in the system that provides a set of services. Examples of hardware entities are processors, disk drives, memory, and adapters. Examples of software entities are database applications, processes, and file systems. Each resource in the system has one or more attributes that define the state of the resource.

resource class

A broad category of system resource, for example: node, file system, adapter. Each resource class has a container that holds the functions, information, dynamic attributes, and conditions that apply to that resource class. For example, the "/tmp space used" condition applies to a file system resource class.

resource manager

A process that maps resource and resource-class abstractions into calls and commands for one or more specific types of resources. A resource manager can be a standalone daemon, or it can be integrated into an application or a subsystem directly.

To see all of the resource classes defined in the system, run the **lsrcsr** command without any flags or parameters. To see all of the resources defined in the system for the **IBM®.FileSystem** resource class, enter:

```
lsrsrc IBM.FileSystem
```

selection string

Must be enclosed within either double or single quotation marks. If the selection string contains double quotation marks, enclose the entire selection string in single quotation marks, for example:

```
-s 'Name == "testing"'  
-s 'Name ?= "test"'
```

Only persistent attributes can be listed in a selection string. For information on how to specify selection strings, see the *RSCT: Administration Guide*.

Flags

- h** Writes the command's usage statement to standard output.
- T** Writes the command's trace messages to standard error. For your software service organization's use only.
- V** Writes the command's verbose messages to standard output.

All RMC commands include a **-T** flag and a **-V** flag. Use the **-T** flag only when your software service organization instructs you to turn tracing on. Trace messages are not translated. Use the **-V** flag, which indicates "verbose" mode, to see more information about the command. Verbose messages are contained in message catalogs and are translated based on the locale in which you are running and other criteria.

Environment Variables

CT_CONTACT

When the CT_CONTACT environment variable is set to a host name or IP address, the command contacts the resource monitoring and control (RMC) daemon on the specified host. If the environment variable is not set, the command contacts the RMC daemon on the local system where the command is being run. The resource class or resources that are displayed or modified by the command are located on the system to which the connection is established.

CT_MANAGEMENT_SCOPE

Determines the management scope that is used for the session with the RMC daemon to monitor and control the resources and resource classes. The management scope determines the set of possible target nodes where the resources and resource classes can be monitored and controlled. The valid values are:

- 0** Specifies *local* scope.
- 1** Specifies *local* scope.
- 2** Specifies *peer domain* scope.
- 3** Specifies *management domain* scope.

If this environment variable is *not* set, *local* scope is used.

rndc.conf File

Purpose

Defines the name server, algorithm, and key for the **rndc** command to use.

Syntax

```
options { server ;  
key ;  
port ;  
address ;
```

```

address-ipv6; };

server { key ;
port ;
host | address ; };

key { algorithm ;
secret " strings " ; };

```

Description

The **rndc.conf** file is the configuration file for the **rndc** command, which is also the BIND 9 name server control utility. The **rndc.conf** file has similar structure and syntax to that of the **named.conf** file. It supports comment styles, such as the C style, the C++ style, and the UNIX style.

The **rndc.conf** file contains three statements: the options statement, the server statement, and the key statement.

options Statement

The *options* statement contains the following attributes:

| Attributes | Definition |
|---------------------|---|
| <i>server</i> | Defines the default name server to be used when the rndc command does not specify a name server. The name or address of a name server can be used in this attribute. |
| <i>key</i> | Defines the default key to authenticate the commands and responses from a server. The key is defined in a key statement. If the rndc command does not specify a key ID, or no key attribute is defined in a matching server statement, the value in this <i>key</i> attribute is used. |
| <i>port</i> | Defines the default port for connection to the remote name server. If the rndc command does not specify a port, or no port attribute is defined in a matching server statement, the value in the <i>port</i> attribute is used. |
| <i>address</i> | Defines the IPv4 source address to be used by default. |
| <i>address-ipv6</i> | Defines the IPv6 source address to be used by default. |

server Statement

| Attributes | Definition |
|------------------------------|--|
| <i>key</i> | Defines the key for the server. The key name must match the name of a key statement in the file. |
| <i>port</i> | Specifies the port to connect to. |
| <i>host</i> <i>address</i> | Specifies the server name or the address of the server. If the address is specified, it is used instead of the server name. Each address can use an optional port. A source address is used to specify IPv4 source address, and a source address of IPv6 is used to specify IPv6 source address. |

key Statement

The *key* statement begins with the name of the key, which is an identifying string.

| Attributes | Definition |
|---------------------------|---|
| <i>algorithm</i> | Identifies the encryption algorithm for the rndc command to use. Only the HMAC-MD5 algorithm is supported currently. |
| <i>secret " strings "</i> | Contains the base-64 encoding of the algorithm encryption key. The base-64 string is enclosed in quotation marks (""). To generate the base-64 string for the <i>secret</i> attribute, you can run the rndc-confgen command. The rndc-confgen command generates a random key for the rndc command. |

Example

In the following example, the **rndc** command uses the server at local host (127.0.0.1) by default, and the key is samplekey.

```
options {
default-server localhost;
default-key samplekey;
};
server localhost {
key samplekey;
};
server testserver {
key testkey;
addresses { localhost port 5353; };
key samplekey {
algorithm hmac-md5;
secret "6FMfj430sz41yb240Ie2iGEz91f11J0+1z";
};
key testkey {
algorithm hmac-md5;
secret "R3HI8P6BKw9ZwXwN3VZKuQ==";
};
```

In the preceding example, the commands to the local host server use the samplekey key, which must also be defined in the configuration file of the server with the same name and secret. The key statement indicates that samplekey uses the HMAC-MD5 algorithm, and its secret attribute contains the base-64 encoding of the HMAC-MD5 secret. If the **rndc -s testserver** command string is used, the **rndc** command will connect to server on local host port 5353 using the key testkey.

Configuration

To accept **rndc** connections and recognize the key specified in the **rndc.conf** file, the name server must be configured with the control statement in the **named.conf** file.

roles File

Purpose

Contains the list of valid roles.

Description

The **/etc/security/roles** file contains the list of valid roles. This is an ASCII file that contains a stanza for each system role. Each stanza is identified by a role name followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute pair ends with a newline character as does each stanza.

The file supports a default stanza. If an attribute is not defined, the default value for the attribute is used, except in the case of the **id** attribute. The **id** attribute must be specified and unique for each role in the file.

A stanza contains the following attributes:

| Attribute | Description |
|--------------------------|---|
| rolelist | Contains a list of roles implied by this role and allows a role to function as a super-role. If the rolelist attribute contains the value of "role1,role2", assigning the role to a user also assigns the roles of <i>role1</i> and <i>role2</i> to that user. |
| authorizations | Contains the list of additional authorizations acquired by the user for this specific role. |
| groups | Contains the list of groups that a user should belong to in order to effectively use this role. The user must be added to each group in this list for this role to be effective. |
| screens | Contains a list of SMIT screen identifiers that allow a role to be mapped to various SMIT screens. The default value for this attribute is * (all screens). |
| msgcat | Contains the file name of the message catalog that contains the one-line descriptions of system roles. |
| msgnum | Contains the message ID that retrieves this role description from the message catalog. |
| id | Specifies the unique numeric ID for the role. This is a required attribute when the system is in enhanced RBAC mode. This is used internally for security decisions. Do not modify the role ID after creating the role. |
| dfltmsg | Contains the default role-description text if message catalogs are not in use. |
| msgset | Contains the message set that contains the role description in the message catalog. |
| auth_mode | Specifies the authentication mode when you assume the role using the swrole command when the system is in the enhanced role-based access control (RBAC) mode. The following values are valid: <ul style="list-style-type: none"> • NONE - No authentication is necessary. • INVOKER - You must enter your own password while calling the swrole command. This is the default value. |
| hostsenabledrole | Specifies the hosts that can download the role definition from the Kernel Role table by using the setkst command. This attribute is intended to be used in a networked environment where the role attributes are shared by multiple hosts. |
| hostsdisabledrole | Specifies the hosts cannot download the role definition from the Kernel Role table by using the setkst command. This attribute is intended to be used in a networked environment where the role attributes are shared by multiple hosts. |

For a typical stanza, see the "Examples" stanza.

Changing the roles File

Do not directly edit the **/etc/security/roles** file. Use the following commands to manipulate the role database:

- **chrole**
- **lsrole**
- **mkrole**
- **rmrole**

The **mkrole** command creates an entry for each new role in the **/etc/security/roles** file. To change the attribute values, use the **chrole** command. To display the attributes and their values, use the **lsrole** command. To remove a role, use the **rmrole** command.

When the system is operating in enhanced RBAC Mode, changes made to the **roles** file do not impact security considerations until the entire roles database is sent to the Kernel Security Tables through the **setkst** command or until the system is rebooted.

To write programs that affect attributes in the **/etc/security/roles** file, use the subroutines listed in Related Information.

Security

The root user and the security group own this file. Read and write access is granted to the root user, and read access to members of the security group. Access for other users and groups depends on the security policy for the system.

Examples

A typical stanza looks like the following example for the ManageAllUsers role:

ManageAllUsers:

```
id = 110
dfltmsg = "Manage all users"
rolelist = ManageBasicUsers
authorizations = UserAdmin,RoleAdmin,PasswdAdmin,GroupAdmin
groups = security
screens = mkuser,rmuser,!tcpip
```

Files

| Item | Description |
|-----------------------------|---|
| /etc/security/roles | Contains the list of valid roles. |
| /etc/security/user.roles | Contains the list of roles for each user. |
| /etc/security/smitacl.group | Contains the group ACL definitions. |
| /etc/security/smitacl.user | Contains the user ACL definitions. |

rpc File for NFS

Purpose

Contains the database for Remote Procedure Calls (RPC) program numbers using NFS.

Description

The **/etc/rpc** file, part the Network Support Facilities, contains names that are used in place of RPC program numbers. These names can be read by users. Each line of the file contains the following entries:

| Entry | Description |
|---|--|
| <i>Name of Server for the RPC Program</i> | Specifies the name of the server daemon that provides the RPC program. |
| <i>RPC Program Number</i> | Specifies the number assigned to the program by the RPC protocol. |
| <i>Aliases</i> | Specifies alternate names by which the service can be requested. |

The three entries for each line are entered in the order listed here. Entries can be separated by any number of blanks or tab characters, provided the line does not wrap. Commented lines in the file must begin with a # (pound sign). Characters in a commented line are not interpreted by routines that search the file.

Examples

A sample `/etc/rpc` file follows:

```
portmapper    100000    portmap sunrpc
rstatd        100001    rstat rup perfmeter
rusersd       100002    rusers
nfs           100003    nfsprog
ypserv         100004    ypprog
mountd        100005    mount showmount
```

sectoldif.cfg Configuration File

Purpose

Defines the names to use for defined data types when generating directory information tree (DIT) data for LDAP.

Description

The **sectoldif.cfg** configuration file is used by the **mksecldap**, **sectoldif**, **nistoldif**, and **rbactoldif** commands when generating output to export to LDAP. This file allows a system administrator to customize the naming used for various data branches that will be created in LDAP. Default names are provided and may be used unless customization is desired. Each entry in the file consist of the following fields:

`Data_Type LDAP_Attribute_Name LDAP_Object_Class LDAP_Value`

| Item | Description |
|----------------------------|---|
| Data_Type | Specifies the data type. Values are USER, GROUP, ID, HOST, SERVICE, PROTOCOL, NETWORK, NETGROUP, RPC, AUTHORIZATION, ROLE, PRIVCMD, PRIVDEV and PRIVFILE. |
| LDAP_Attribute_Name | Specifies the LDAP attribute name. |
| LDAP_Object_Class | Specifies the LDAP object class associated with LDAP_Attribute_Name . |
| LDAP_Value | Specifies the LDAP attribute value. |

The **Data_Type** field must be one of the recognized types. The remaining fields in an entry are configurable by the system administrator. System administrator must ensure that the **LDAP_Object_Class** field is appropriate for the supplied **LDAP_Attribute_Name** as the commands do not verify the combination.

Examples

1. The following modifications to **sectoldif.cfg** will cause users to be exported to *ou=Employees,o=ibm* and groups to *ou=Departments,o=ibm* when *-d o=ibm* is specified for the **sectoldif** command:

| | | | |
|-------|----|--------------------|-------------|
| USER | ou | organizationalUnit | Employees |
| GROUP | ou | organizationalUnit | Departments |

2. The following modifications to **sectoldif.cfg** will cause an AIX compliant DIT and data to be created when **sectoldif -d cn=aixsecdb,cn=aixdata -S aix** is invoked:

| | | | |
|-------|----|--------------------|----------|
| USER | ou | organizationalUnit | aixuser |
| GROUP | ou | organizationalUnit | aixgroup |
| ID | ou | organizationalUnit | system |

security_default File

Purpose

Contains the NFS security defaults.

Description

The **/etc/nfs/security_default** file contains the list of security flavors that may be used by the NFS client, in the order in which they should be used. The list of valid security flavors are:

| | |
|-------|-------------------------------------|
| sys | UNIX style (uids, gids) |
| dh | DES style (encrypted timestamps) |
| krb5 | Kerberos 5, no integrity or privacy |
| krb5i | Kerberos 5, with integrity |
| krb5p | Kerberos 5, with privacy |

This file may be modified using the **chnfssec** command.

The format of the **/etc/nfs/security_default** file is one security flavor (sys, krb5, etc.) per line.

Files

| Item | Description |
|----------------------------------|-----------------------------------|
| /etc/nfs/security_default | The security_default file. |

sendmail.cf File

Purpose

Contains the configuration information for the **sendmail** command.

Description

The **/etc/mail/sendmail.cf** configuration file contains the configuration information for the **sendmail** command. Information contained in this file includes such items as the host name and domain, and the **sendmail** rule sets.

The **/etc/mail/sendmail.cf** file:

- Stores information about the type of mailer programs running.

- Defines how the **sendmail** command rewrites addresses in messages.
- Defines how the **sendmail** command operates in the following environments:
 - Local mail delivery
 - Local area network delivery using TCP/IP
 - Remote delivery using Basic Utilities Network (BNU).

If your environment includes only these types of mail delivery, you can use the supplied **/etc/mail/sendmail.cf** file with few, if any, changes.

Control Lines

The **/etc/mail/sendmail.cf** file consists of a series of control lines, each of which begins with a single character defining how the rest of the line is used. Lines beginning with a space or a tab are continuation lines. Blank lines and lines beginning with a # (pound sign) are comments. Control lines are used for defining:

- Macros and classes for use within the configuration file
- Message headings
- Mailers
- Options for the **sendmail** command

Each of these control line types are discussed in detail below.

Rewrite Rules

The **sendmail** command receives addresses in a number of different formats because different mailers use different formats to deliver mail messages. The **sendmail** command changes the addresses to the format needed to route the message for the mailer program being used. To perform this translation, the **sendmail** command uses a set of rewrite rules, or *rule sets*, that are defined in the **/etc/mail/sendmail.cf** configuration file. Rewrite rules have the following format:

| | | |
|---------|--|-------|
| Snumber | | |
| Rbefore | | after |

where number is a integer greater than or equal to zero indicating which rule set this is, and before and after are symbolic expressions representing a particular pattern of characters. The line beginning with R means rewrite the expression before so that it has the same format as the expression after. **Sendmail** scans through the set of rewrite rules looking for a match on the left-hand side (LHS) of the rule. When a rule matches, the address is replaced by the right-hand side (RHS) of the rule.

Note: There must be at least one TAB character (ASCII code 0x09) between the before and after sections of the **/etc/mail/sendmail.cf** file. For this reason, any editor that translates TAB characters into a series of spaces (ASCII code 0x20) may not be used to edit the **/etc/mail/sendmail.cf** file. For example, the GNU eMacs editor can corrupt the **sendmail.cf** file, but the vi editor does not.

The **/etc/mail/sendmail.cf** file installed with the **sendmail** command contains enough rules to perform the translation for BNU and TCP/IP networks using a domain address structure. You should not have to change these rules unless connecting to a system that uses a different addressing scheme.

Macro expansions of the form \$x are performed when the configuration file is read. Expansions of the form \$&x are performed at run time, using a somewhat less general algorithm. This form is intended only for referencing internally defined macros such as \$h that are changed at runtime.

Left-Hand Side (LHS) of Rewrite Rules

The left-hand side of rewrite rules contains a pattern. Normal words are simply matched directly. Metasyntax is introduced using a dollar sign. The metasymbols are:

| Metasymbol | Meaning |
|------------|-------------------------------|
| \$* | Match zero or more tokens |
| \$+ | Match one or more tokens |
| \$- | Match exactly one token |
| \$=x | Match any phrase in class x |
| \$~x | Match any word not in class x |

If any of these match, they are assigned to the symbol \$n for replacement on the right-hand side, where n is the index in the LHS. For example, if the LHS:

\$-:\$+

is applied to the input:

UCBARPA:linda

the rule will match, and the values passed to the RHS will be:

\$1 UCBARPA
\$2 linda

Right-Hand Side (RHS) of Rewrite Rules

When the left-hand side of a rewrite rule matches, the input is deleted and replaced by the right-hand side. Tokens are copied directly from the RHS unless they begin with a dollar sign. Metasymbols are:

| Metasymbol | Meaning |
|---------------------------------------|--|
| \$n | Substitute indefinite token n from LHS |
| [\$name\$] | Canonicalize name |
| \$(map key\$@arguments \$:default \$) | Generalized keyed mapping function |
| \$>n | "Call" ruleset n |
| \$#mailer | Resolve to mailer |
| \$@host | Specify host |
| \$:user | Specify user |

The \$n syntax substitutes the corresponding value from a \$+, \$-, \$*, \$=, or \$~ match on the LHS. It may be used anywhere.

A host name enclosed between \$[and \$] is looked up in the host database(s) and replaced by the canonical name. For example, \$[merlin] might become merlin.magician and \$[[128.32.130.2]\$] would become king.arthur.

The \$(...) syntax is a more general form of lookup; it uses a named map instead of an implicit map. If no lookup is found, the indicated default is inserted; if no default is specified and no lookup matches, the value is left unchanged. The arguments are passed to the map for possible use.

The \$>n syntax causes the remainder of the line to be substituted as usual and then passed as the argument to ruleset n. The final value of ruleset n then becomes the substitution for this rule. The \$> syntax can only be used at the beginning of the right hand side; it can be only be preceded by \$@ or \$:.

The \$# syntax should only be used in ruleset zero or a subroutine of ruleset zero. It causes evaluation of the ruleset to terminate immediately, and signals to **sendmail** that the address has completely resolved.

The complete syntax is:

\$#mailer \$@host \$:user

This specifies the {mailer, host, user} 3-tuple necessary to direct the mailer. If the mailer is local, the host part may be omitted. The mailer must be a single word, but the host and user may be multi-part. If the mailer is the built-in IPC mailer, the host may be a colon-separated list of hosts that are searched in order for the first working address, exactly like MX (machine exchange) records. The user is later rewritten by the mailer-specific envelope rewrite set and assigned to the \$u macro. As a special case, if the value to \$# is "local" and the first character of the \$: value is "@", the "@" is stripped off, and a flag is set in the address descriptor that causes **sendmail** to not do ruleset 5 processing.

Normally, a rule that matches is retried, that is, the rule loops until it fails. An RHS may also be preceded by a \$@ or a \$: to change this behavior. A \$@ prefix causes the ruleset to return with the remainder of the RHS as the value. A \$: prefix causes the rule to terminate immediately, but the ruleset to continue; this can be used to avoid continued application of a rule. The prefix is stripped before continuing.

The \$@ and \$: prefixes may precede a \$> spec. For example:

```
R$+ $: $>7 $1
```

matches anything, passes that to ruleset seven, and continues; the \$: is necessary to avoid an infinite loop.

Substitution occurs in the order described; that is, parameters from the LHS are substituted, host names are canonicalized, "subroutines" are called, and finally \$#,\$@, and \$: are processed.

Semantics of Rewrite Rule Sets

There are five rewrite sets that have specific semantics.

Ruleset three should turn the address into "canonical form." This form should have the basic syntax:

```
local-part@host-domain-spec
```

Ruleset three is applied by **sendmail** before doing anything with any address.

If no "@" sign is specified, then the host-domain-spec may be appended (box "D" in "Rewrite Set Semantics") from the sender address (if the C flag is set in the mailer definition corresponding to the sending mailer).

Ruleset zero is applied after ruleset three to addresses that are going to actually specify recipients. It must resolve to a {mailer, host, user} triple. The mailer must be defined in the mailer definitions from the configuration file. The host is defined into the \$h macro for use in the argv expansion of the specified mailer.

IPC Mailers

Some special processing occurs if the ruleset zero resolves to an IPC mailer (that is, a mailer that has "[IPC]" listed as the Path in the M configuration line. The host name passed after "\$@" has MX expansion performed; this looks the name up in DNS to find alternate delivery sites.

The host name can also be provided as a dotted quad in square brackets; for example:
[128.32.149.78]

This causes direct conversion of the numeric value to a TCP/IP host address.

The host name passed in after the "\$@" may also be a colon-separated list of hosts. Each is separately MX expanded and the results are concatenated to make (essentially) one long MX list. The intent here is to create "fake" MX records that are not published in DNS for private internal networks.

As a final special case, the host name can be passed in as a text string in square brackets:

[any.internet.addr]

This form avoids the MX mapping if the F=0 flag is set for the selected delivery agent.

Note: This is intended only for situations where you have a network *firewall* (a system or machine that controls the access between outside networks and private networks) or other host that will do special processing for all your mail, so that your MX record points to a gateway machine. This machine could then do direct delivery to machines within your local domain. Use of this feature directly violates RFC 1123 section 5.3.5: it should not be used lightly.

Macros in the sendmail.cf File

Macros in the */etc/mail/sendmail.cf* file are interpreted by the **sendmail** command. A macro is a symbol that represents a value or string. A macro is defined by a D command in the */etc/mail/sendmail.cf* file.

D — Define Macro

Macros are named with a single character or with a word in {braces}. Single-character names may be selected from the entire ASCII set, but user-defined macros should be selected from the set of uppercase letters only. Lowercase letters and special symbols are used internally. Long names beginning with a lowercase letter or a punctuation character are reserved for use by **sendmail**, so user-defined long macro names should begin with an uppercase letter.

The syntax for macro definitions is:

Dxval

where x is the name of the macro (which may be a single character or a word in braces) and val is the value it should have. There should be no spaces given that do not actually belong in the macro value.

Macros are interpolated using the construct \$x, where x is the name of the macro to be interpolated. This interpolation is done when the configuration file is read, except in M lines. The special construct \$&x can be used in R lines to get deferred interpolation.

Conditionals can be specified using the syntax:

\$?x text1 \$| text2 \$.

This interpolates text1 if the macro \$x is set, and text2 otherwise. The "else" (\$!) clause may be omitted.

Lowercase macro names are reserved to have special semantics, used to pass information in or out of **sendmail**, and special characters are reserved to provide conditionals, and so on. Uppercase names (that is, \$A through \$Z) are specifically reserved for configuration file authors.

The following macros are defined and/or used internally by **sendmail** for interpolation into argv's for mailers or for other contexts. The ones marked - are information passed into **sendmail**, the ones marked = are information passed both in and out of **sendmail**, and the unmarked macros are passed out of **sendmail** but are not otherwise used internally:

| Macro | Definition |
|-------------------------------------|---|
| <code>\$_</code> | RFC1413-validation & IP source route (V8.1 and above). |
| <code>\$a</code> | The origin date in RFC822 format. |
| <code>\$(auth_authen)</code> | The client's authentication credentials as determined by authentication (only set if successful). The format depends on the mechanism used, it might be just <code>user</code> , or <code>user@realm</code> , or something similar (SMTP AUTH only). |
| <code>\$(auth_author)</code> | The authorization identity, that is the AUTH=parameter of the SMTP MAIL command if supplied. |
| <code>\$(alg_bits)</code> | The maximum key length (in bits) of the symmetric encryption algorithm used for a TLS connection. This may be less than the effective key length, which is stored in <code>\$(cipher_bits)</code> , for export controlled algorithms. |
| <code>\$(addr_type)</code> | The type of the address which is currently being rewritten. This macro contains up to three characters, the first is either <code>e</code> or <code>h</code> for envelope/header address, the second is a space, and the third is either <code>s</code> or <code>r</code> for sender/recipient address. |
| <code>\$(auth_type)</code> | The mechanism used for SMTP authentication (only set if successful). |
| <code>\$b</code> | The current date in RFC822 format. |
| <code>\$(bodytype)</code> | The <i>ESMTP BODY</i> parameter. |
| <code>\$B</code> | The BITNET relay. |
| <code>\$c</code> | The hop count. |
| <code>\$(client_addr)</code> | The connecting host's IP address. |
| <code>\$(cert_issuer)</code> | The DN (distinguished name) of the CA (certificate authority) that signed the presented certificate (the cert issuer) (STARTTLS only). |
| <code>\$(cert_md5)</code> | The MD5 hash of the presented certificate (STARTTLS only). |
| <code>\$(client_name)</code> | The connecting host's canonical name. |
| <code>\$(client_port)</code> | The connecting host's port name. |
| <code>\$(client_resolve)</code> | Holds the result of the resolve call for <code>\$(client_name)</code> . |
| <code>\$(cert_subject)</code> | The DN of the presented certificate (called the cert subject) (STARTTLS only). |
| <code>\$(currHeader)</code> | Header value as quoted string. |
| <code>\$(cipher)</code> | The cipher suite used for the connection, for example, EDH-DSS-DES-CBC3-SHA, EDH-RSA-DESCBC-SHA, DES-CBC-MD5, and DES-CBC3-SHA (STARTTLS only). |
| <code>\$(cipher_bits)</code> | The effective key length (in bits) of the symmetric encryption algorithm used for a TLS connection. |
| <code>\$(client_connections)</code> | The number of open connections in the SMTP server for the client IP address. |
| <code>\$(client_flags)</code> | The flags specified by the Modifier= part of ClientPortOptions where flags are separated from each other by spaces and upper case flags are doubled. That is, Modifier= <code>hA</code> is represented as <code>h AA</code> in <code>\$(client_flags)</code> , which is required for testing the flags in rulesets. |
| <code>\$(client_ptr)</code> | The result of the PTR lookup for the client IP address. |
| <code>\$(client_rate)</code> | Note: This is the same as <code>\$(client_name)</code> if and only if <code>\$(client_resolve)</code> is OK. This is defined in the SMTP server only. |
| <code>\$(client_resolve)</code> | The number of incoming connections for the client IP address over the time interval specified by ConnectionWindowSize. |
| | Holds the result of the resolve call for <code>\$(client_name)</code> . The possible values are: |
| | <ul style="list-style-type: none"> • OK: Resolved successfully • FAIL: Permanent lookup failure • FORGED: Forward lookup does not match reverse lookup • TEMP: Temporary lookup failure |
| <code>\$(cn_issuer)</code> | This is defined in the SMTP server only. The <code>sendmail</code> command performs a hostname lookup on the IP address of the connecting client. Next the IP addresses of that hostname are looked up. If the client IP address does not appear in that list, then the hostname is forged. This is reflected as the value FORGED for <code>\$(client_resolve)</code> , and it also shows up in <code>\$_</code> as (may be forged). |
| | The CN (common name) of the CA that signed the presented certificate (STARTTLS only). |
| | Note: If the CN can not be extracted properly it is replaced by one of these strings based on the encountered error: |
| | <code>BadCertificateContainsNUL</code> . The CN contains a NULL character |
| | <code>BadCertificateTooLong</code> CN is too long |
| | <code>BadCertificateUnknown</code> CNcould not be extracted |
| | In the last case, some other (unspecific) error occurred. |
| <code>\$(cn_subject)</code> | The CN (common name) of the presented certificate (STARTTLS only). See <code>\$(cn_issuer)</code> for possible replacements. |
| <code>\$(currHeader)</code> | Header value as quoted string (possibly truncated to MAXNAME). This macro is only available in header check rulesets. |
| <code>\$C</code> | The hostname of the DECnet relay (m4 technique). |

| Macro | Definition |
|---------------------------|---|
| \$d | enrealThe current date in UNIX (<i>ctime</i> (3) format. |
| \$daemon_addr | The IP address on which the daemon is listening for connections. Unless DaemonPortOptions is set, this will be 0.0.0.0 . |
| \$daemon_family | If the daemon is accepting network connections, this is the network family. |
| \$daemon_flags | The flags for the daemon as specified by the Modifiers= part of DaemonPortOptions where the flags are separated from each other by spaces and upper case flags are doubled. |
| \$daemon_info | Information about a daemon as a text string. For example, SMTP+queueing@00 . |
| \$daemon_name | The name of the daemon from DaemonPortOptions Name= suboption. If this suboption is not used, the default will be set to Daemon#, where # is the daemon number. |
| \$daemon_port | The port on which the daemon is accepting connections. Unless DaemonPortOptions is set, this will most likely be set to the default of 25. |
| \$(deliveryMode) | The current delivery mode used by sendmail . |
| \$e | Obsolete. Used SmtpGreetingMessage option instead. |
| \$envid | The original DSN envelope ID. |
| \$E | X400 relay (unused) (m4 technique). |
| \$f | The sender's address. |
| \$F | FAX relay (m4 technique). |
| \$g | The sender's address relative to the recipient. |
| \$h | Host part of the recipient address. |
| \${hdrlen} | The length of the header value which is stored in \$(currHeader) (before possible truncation). If this value is greater than or equal to MAXNAME the header has been truncated. |
| \${hdr_name} | The name of the header field for which the current header check ruleset has been called. This is useful for a default header check ruleset to get the name of the header; the macro is only available in header check rulesets. |
| \$H | The mail hub (m4 technique). |
| \${hdrlen} | The length of the header value, which is stored in \$(currHeader) . |
| \${hdr_name} | The name of the header field for which the current header check ruleset has been called. |
| \$i | The queue identifier. |
| \${if_addr} | The IP address of an incoming connection interface unless it is in the loopback net. |
| \${if_addr_out} | The IP address of the interface of an outgoing connection unless it is in the loopback net. The IPv6 addresses are tagged with IPv6: before the address. |
| \${if_family} | The IP family of the interface of an incoming connection unless it is in the loopback net. |
| \${if_family_out} | The IP family of the interface of an outgoing connection unless it is in the loopback net. |
| \${if_name} | The name of an incoming connection interface. |
| \${if_name_out} | The name of the interface of an outgoing connection. |
| \$j= | The official canonical name. |
| \$k | The UUCP node name (V8.1 and above). |
| \${load_avg} | The current load average. |
| \${msg_id} | The value of the Message-Id: header. |
| \${msg_size} | The value of the SIZE= parameter, that is, usually the size of the message (in an ESMTP dialogue), before the message has been collected, thereafter the message size as computed by the sendmail command. |
| \${nbadrcpts} | The number of bad recipients for a single message. |
| \${nrcpts} | The number of validated recipients for a single message. |
| \${time} | Note: Since recipient validation happens after check_rcpt has been called, the value in this ruleset is one less than what might be expected. |
| \${time} | The output of the time(3) function, that is, the number of seconds since 0 hours, 0 minutes, 0 seconds, January 1, 1970, Coordinated Universal Time (UTC). |
| \${tls_version} | The TLS/SSL version used for the connection, for example, TLSv1, SSLv3, and SSLv2; defined after STARTTLS has been used. |
| \${total_rate} | The total number of incoming connections over the time interval specified by Connection-RateWindowSize. |

| Macro | Definition |
|----------------------------------|--|
| <code> \${verify}</code> | The result of the verification of the presented cert, only defined after STARTTLS has been used (or attempted). The possible values are: <ul style="list-style-type: none"> • OK: Verification succeeded. • NO: Nocert presented. • NOT: No cert requested. • FAIL: cert presented but could not be verified, for example, the signing CA is missing. • NONE: STARTTLS has not been performed. • TEMP: Temporary error occurred. • PROTOCOL: Some protocol error occurred. • SOFTWARE STARTTLS: The handshake failed, which is a fatal error for this session, the e-mail is queued. |
| Item | Description |
| <code> \$l</code> | Obsolete. Use <code>UnixFromLine</code> option instead. |
| <code> \$L</code> | Local user relay (m4 technique). |
| <code> \$m</code> | The DNS domain name (V8.1 and above). |
| <code> \$M</code> | Who we are masquerading as (m4 technique). |
| <code> \$(mail_addr)</code> | The address part of the resolved triple of the address given for the <code>SMTP MAIL</code> command. |
| <code> \$(mail_host)</code> | The host from the resolved triple of the address given for the <code>SMTP MAIL</code> command. |
| <code> \$(mail_mailer)</code> | The mailer from the resolved triple of the address given for the <code>SMTP MAIL</code> command. |
| <code> \$n</code> | The error messages sender. |
| <code> \$(ntries)</code> | The number of delivery attempts. |
| <code> \$o</code> | Obsolete. Use <code>OperatorChars</code> option instead. |
| <code> \$opMode</code> | The startup operating mode (V8.7 and above). |
| <code> \$p</code> | The <code>sendmail</code> process ID. |
| <code> \$q-</code> | Default form of the sender address. |
| <code> \$(queue_interval)</code> | The queue run interval as defined in the <code>-q</code> flag. |
| <code> \$r</code> | The protocol used. |
| <code> \$R</code> | The relay for unqualified names (m4 technique). |
| <code> \$(rcpt_addr)</code> | The address part of the resolved triple of the address given for the <code>SMTP RCPT</code> command. |
| <code> \$(rcpt_host)</code> | The host from the resolved triple of the address given for the <code>SMTP RCPT</code> command. |
| <code> \$(rcpt_mailer)</code> | The mailer from the resolved triple of the address given for the <code>SMTP RCPT</code> command. |
| <code> \$s</code> | The sender's host name. |
| <code> \$S</code> | The Smart host (m4 technique). |
| <code> \$(server_addr)</code> | The address of the server of the current outgoing SMTP connection. |
| <code> \$(server_name)</code> | The name of the server of the current outgoing SMTP connection. |
| <code> \$t</code> | Current time in seconds. |
| <code> \$u</code> | The recipient's user name. |
| <code> \$U</code> | The UUCP name to override <code>\$k</code> . |
| <code> \$v</code> | The <code>sendmail</code> program's version. |
| <code> \$V</code> | The UUCP relay (for class <code>\$=V</code>) (m4 technique). |
| <code> \$w</code> | The short name of this host. |
| <code> \$W</code> | The UUCP relay (for class <code>\$=W</code>) (m4 technique). |
| <code> \$x</code> | The full name of the sender. |
| <code> \$X</code> | The UUCP relay (for class <code>\$=X</code>) (m4 technique). |
| <code> \$y</code> | The home directory of the recipient. |
| <code> \$z</code> | The name of the controlling TTY. |
| <code> \$Y</code> | The UUCP relay for unclassified hosts. |
| <code> \$z</code> | The recipient's home directory. |
| <code> \$Z</code> | The version of this m4 configuration (m4 technique). |

There are three types of dates that can be used. The `$a` and `$b` macros are in RFC 822 format; `$a` is the time as extracted from the "Date:" line of the message (if there was one), and `$b` is the current date and time (used for postmarks). If no "Date:" line is found in the incoming message, `$a` is set to the current time also. The `$d` macro is equivalent to the `$b` macro in UNIX (ctime) format. The `$t` macro is the current time in seconds.

The macros **\$w**, **\$j**, and **\$m** are set to the identity of this host. **Sendmail** tries to find the fully qualified name of the host if at all possible; it does this by calling `gethostname(2)` to get the current hostname and then passing that to `gethostbyname(3)` which is supposed to return the canonical version of that host name. Assuming this is successful, **\$j** is set to the fully qualified name, and **\$m** is set to the domain part of the name (everything after the first dot). The **\$w** macro is set to the first word (everything before the first dot) if you have a level 5 or higher configuration file; otherwise, it is set to the same value as **\$j**. If the canonicalization is not successful, it is imperative that the config file set **\$j** to the fully qualified domain name.

The **\$f** macro is the ID of the sender as originally determined; when mailing to a specific host, the **\$g** macro is set to the address of the sender relative to the recipient. For example, if a user sends to `king@castle.com` from the machine `vangogh.painter.com`, the **\$f** macro will be `vincent` and the **\$g** macro will be `vincent@vangogh.painter.com`.

The **\$x** macro is set to the full name of the sender. This can be determined in several ways. It can be passed as flag to **sendmail**. It can be defined in the NAME environment variable. The third choice is the value of the "Full-Name:" line in the header if it exists, and the fourth choice is the comment field of a "From:" line. If all of these fail, and if the message is being originated locally, the full name is looked up in the `/etc/passwd` file.

When sending, the **\$h**, **\$u**, and **\$z** macros get set to the host, user, and home directory (if local) of the recipient. The first two are set from the **\$@** and **\$:** part of the rewrite rules, respectively.

The **\$p** and **\$t** macros are used to create unique strings (for example, for the "Message-Id:" field). The **\$i** macro is set to the queue ID on this host; if put into the timestamp line, it can be useful for tracking messages. The **\$v** macro is set to be the version number of **sendmail**; this is normally put in timestamps and has been proven useful for debugging.

The **\$c** field is set to the "hop count," that is, the number of times this message has been processed. This can be determined by the **-h** flag on the command line or by counting the timestamps in the message.

The **\$r** and **\$s** fields are set to the protocol used to communicate with **sendmail** and the sending hostname. They can be set together using the **-p** command line flag or separately using the **-M** or **-oM** flags.

The **\$_** is set to a validated sender host name. If the sender is running an RFC 1413 compliant IDENT server and the receiver has the IDENT protocol turned on, it will include the user name on that host.

The **\$(client_name)**, **\$(client_addr)**, and **\$(client_port)** macros are set to the name, address, and port number of the connecting host who is invoking **sendmail** as a server. These can be used in the **check_*** rulesets (using the **\$&** deferred evaluation form).

Changing the Domain Name Macro

The domain name macro, **DD**, specifies the full domain name of your local group of hosts. The format of the domain name macro is **DD** followed by, at most, four period-separated names, for example:

DDname1.name2.name3.name4

This macro can be set automatically through the **hostname** command. The **sendmail** command reads what has been set with the **hostname** command and uses it to initialize the host and domain macros and classes. The configuration file macros only need to be changed if you want the **sendmail** host and domain names to be different from those set by the **hostname** command.

To change the domain name macro:

1. Enter the command:

- ```
vi /etc/mail/sendmail.cf
```
2. Find the line beginning with **Dd**.
  3. Replace what follows **Dd** with your domain name. For example, if your domain name is **newyork.abc.com**, enter:  
**DDnewyork.abc.com**
  4. Save the file and exit the editor.

### Changing the Host Name Macro

The host name macro, **Dw**, specifies the name of your host system used in the return address of all messages you generate. The format of the host name macro is **Dw** followed by the hostname of this machine, for example:

**Dwhostname**

By default, the **sendmail** command reads what has been set with the **hostname** command and uses it to initialize the host and domain name macros and classes. Change the configuration file macros only if you want the **sendmail** command host and domain names to be different from those set by the **hostname** command.

To change the host name macro:

1. Enter the command:  

```
vi /etc/mail/sendmail.cf
```
2. Find the line beginning with **Dw**.
3. Replace what follows **Dw** with your hostname. For example, if your hostname is **brown**, enter:  
**Dwbrown**
4. Save the file and exit the editor.

**Note:** If the **Dw** macro is defined, you must also define the **CW** (hostname) class.

### Modifying the sendmail.cf File

Before you modify the **/etc/mail/sendmail.cf** file, make a backup copy. Do this by executing the following command:

```
cp /etc/mail/sendmail.cf /etc/mail/sendmail.cf.working
```

If the changes you make cause the mail system not to work properly, you can return to using a copy of the **/etc/mail/sendmail.cf** file that you know works.

You can modify the **/etc/mail/sendmail.cf** file by using your favorite text editor. However, some editors store tabs as the number of spaces they represent, not the tab character itself. This can cause unexpected results if the tab character is defined as the field-separator character in rule sets. Use the **vi** editor to avoid this problem, or change the field-separator character with the **J** option. (For ease of reference, this discussion assumes you use the **vi** editor to modify the **/etc/mail/sendmail.cf** file.)

After changing any information in the **/etc/mail/sendmail.cf** file, you must instruct the daemon to reread the file. See section, “Making the sendmail Daemon Reread the Configuration Information” for those instructions.

### Making the sendmail Daemon Reread the Configuration Information

After you have made changes to the **sendmail.cf** file, instruct the daemon to reread the file. If you started the **sendmail** command using the **starts** command, enter the command:

```
refresh -s sendmail
```

Or, if you started the **sendmail** daemon using the **/usr/sbin/sendmail** command, enter the command:

```
kill -1 `cat /etc/mail/sendmail.pid`
```

Both of these commands cause the daemon to reread the **/etc/mail/sendmail.cf** file, the **/etc/mail/aliases** file, and the **/etc/sendmail.nl** file.

## Alias Database

The alias database exists in two forms. One is a text form, maintained in the file **/etc/mail/aliases**. The aliases are of the form:

```
name: name1, name2, ...
```

Only local names may be aliased. For example:

```
linda@cloud.ai.acme.org: linda@CS.
```

has the desired effect. Aliases may be continued by starting any continuation lines with a space or a tab. Blank lines and lines beginning with a pound sign (#) are comments.

The second form is processed by the new database manager (NDBM) or Berkeley DB library. This form is in the file **/etc/mail/aliases.db** (if using NEWDB) or **/etc/mail/aliases.dir** and **/etc/mail/aliases.pag** (if using NDBM). This is the form that **sendmail** actually uses to resolve aliases. This technique is used to improve performance.

The service switch sets the control of search order. The following entry

```
AliasFile=switch:aliases
```

is always added as the first alias entry. The first alias file name without a class (for example, without nis on the front) will be used as the name of the file for a "files" entry in the aliases switch. For example, if the configuration file contains

```
AliasFile=/etc/mail/aliases
```

and the service switch contains

```
aliases nis files nisplus
```

then aliases will first be searched in the NIS database, then in **/etc/mail/aliases**, and finally in the NIS+ database.

## Rebuilding the Alias Database

The DB or DBM version of the database may be rebuilt explicitly by executing the command:

```
newaliases
```

This is equivalent to giving **sendmail** the **-bi** flag:

```
/usr/sbin/sendmail -bi
```

If the **RebuildAliases** option is specified in the configuration, **sendmail** will rebuild the alias database automatically if possible when it is out of date. Auto-rebuild can be dangerous on heavily loaded machines with large alias files. If it might take more than the rebuild time-out (option **AliasWait**, which is normally five minutes) to rebuild the database, there is a chance that several processes will start the rebuild process simultaneously.

If you have multiple aliases databases specified, the **-bi** flag rebuilds all the database types. It understands, for example, it can rebuild NDBM databases, but not NIS databases.

## Potential Problems with the Alias Database

There are a number of problems that can occur with the alias database. They all result from a **sendmail** process accessing the DBM version while it is only partially built. This can happen under two circumstances: One process accesses the database while another process is rebuilding it, or the process rebuilding the database dies (due to being killed or a system crash) before completing the rebuild.

**Sendmail** has three techniques to try to relieve these problems. First, it ignores interrupts while rebuilding the database; this avoids the problem of someone aborting the process leaving a partially rebuilt database. Second, it locks the database source file during the rebuild, but that may not work over NFS or if the file is not writable. Third, at the end of the rebuild, it adds an alias of the form:

@: @

(which is not normally legal). Before **sendmail** will access the database, it checks to ensure that this entry exists.

### List Owners

If an error occurs on sending to a certain address, *x*, **sendmail** will look for an alias of the form *owner-x* to receive the errors. This is typically useful for a mailing list where the submitter of the list has no control over the maintenance of the list itself. In this case, the list maintainer would be the owner of the list. For example:

```
unix-wizards: linda@paintbox, wnj@monet, nosuchuser,
 sam@matisse
owner-unix-wizards: unix-wizards-request
unix-wizards-request: linda@paintbox
```

would cause *linda@paintbox* to get the error that will occur when someone sends to *unix-wizards* due to the inclusion of *nosuchuser* on the list.

List owners also cause the envelope sender address to be modified. The contents of the owner alias are used if they point to a single user. Otherwise, the name of the alias itself is used. For this reason, and to conform to Internet conventions, the "owner-" address normally points at the "-request" address; this causes messages to go out with the typical Internet convention of using "list-request" as the return address.

### Per-User Forwarding (.forward Files)

As an alternative to the alias database, users may put a file with the name ".forward" in their home directory. If this file exists, **sendmail** redirects mail for that user to the list of addresses listed in the **.forward** file. For example, if the home directory for user "kenly" has a **.forward** file with contents:

```
kenly@ernie
joel@renoir
```

then any mail arriving for "kenly" will be redirected to the specified accounts.

The configuration file defines a sequence of file names to check. By default, this is the user's **.forward** file, but can be defined to be more general using the **ForwardPath (J)** option. If you change this option, you must inform your user base of the change.

### IDENT Protocol Support

UCB **sendmail** supports the IDENT protocol as defined in RFC 1413. Although this enhances identification of the author of an e-mail message by doing a "callback" to the originating system to include the owner of a particular TCP connection in the audit trail, it is in no sense perfect; a determined forger can easily violate the security of the IDENT protocol.

**Note:** The operating system does not support the IDENT protocol. The IDENT timeout is set to zero (0) in the `/etc/mail/sendmail.cf` file to disable IDENT. Modify your `sendmail.cf` file and set IDENT time-out if you wish to enable IDENT.

The following description is excerpted from RFC 1413:

## 6. Security Considerations

The information returned by this protocol is at most as trustworthy as the host providing it OR the organization operating the host. For example, a PC in an open lab has few if any controls on it to prevent a user from having this protocol return any identifier the user wants. Likewise, if the host has been compromised the information returned may be completely erroneous and misleading.

The Identification Protocol is not intended as an authorization or access control protocol. At best, it provides some additional auditing information with respect to TCP connections. At worst, it can provide misleading, incorrect, or maliciously incorrect information.

The use of the information returned by this protocol for other than auditing is strongly discouraged. Specifically, using Identification Protocol information to make access control decisions, either as the primary method (that is, no other checks) or as an adjunct to other methods may result in a weakening of normal host security.

An Identification server may reveal information about users, entities, objects or processes which might normally be considered private. An Identification server provides service which is a rough analog of the CallerID services provided by some phone companies and many of the same privacy considerations and arguments that apply to the CallerID service apply to Identification. If you would not run a "finger" server due to privacy considerations you may not want to run this protocol.

## Tuning

There are a number of configuration parameters you may want to change, depending on the requirements of your site. Most of these are set using an option in `sendmail.cf`. For example, the line "O Time-out.queuereturn=5d" sets option "Timeout.queuereturn" to the value "5d" (five days).

Most of these options have appropriate defaults for most sites. However, sites having very high mail loads may find they need to tune them as appropriate for their mail load. In particular, sites experiencing a large number of small messages, many of which are delivered to many recipients, may find that they need to adjust the parameters dealing with queue priorities.

All prior versions of `sendmail` had single-character option names. Although old short names are still accepted, most new options do not have short equivalents.

## Timeouts

All time intervals are set using a scaled syntax. For example, "10m" represents ten minutes, whereas "2h30m" represents two and a half hours. The full set of scales is:

|          |         |
|----------|---------|
| <b>s</b> | seconds |
| <b>m</b> | minutes |
| <b>h</b> | hours   |
| <b>d</b> | days    |
| <b>w</b> | weeks   |

## Read Timeouts

Timeouts all have option names "Time-out.suboption". The recognized suboptions, their default values, and the minimum values allowed by RFC 1123 section 5.3.2 are:

| Suboption               | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aconnect                | The overall timeout waiting for all connection for a single delivery attempt to succeed [0, unspecified]. If 0, no overall limit is applied. This can be used to restrict the total amount of time trying to connect to a long list of host that could accept an e-mail for the recipient. This timeout does not apply to <b>FallbackMXhost</b> , that is, if the time is exhausted, the <b>FallbackMXhost</b> is tried next. |
| auth                    | The timeout for a reply in an SMTP AUTH dialogue [10m, unspecified].                                                                                                                                                                                                                                                                                                                                                          |
| command-connect         | In server SMTP, the time to wait for another command. [1h, 5m].                                                                                                                                                                                                                                                                                                                                                               |
| control                 | The time to wait for an SMTP connection to open (the connect(2) system call) [0, unspecified]. If zero, uses the kernel default. In no case can this option extend the time-out longer than the kernel provides, but it can shorten it. This is to get around kernels that provide an extremely long connection time-out (90 minutes in one case).                                                                            |
| datablock-              | The time-out for a complete control socket transaction to complete [2m, none].                                                                                                                                                                                                                                                                                                                                                |
| datafinal-              | The wait for reading a data block (that is, the body of the message). [1h, 3m]. This should be long because it also applies to programs piping input to <b>sendmail</b> which have no guarantee of promptness.                                                                                                                                                                                                                |
| datainit-fileopen       | The wait for a reply from the dot terminating a message. [1h, 10m]. If this is shorter than the time actually needed for the receiver to deliver the message, duplicates will be generated. This is discussed in RFC1047.                                                                                                                                                                                                     |
| iconnect                | The wait for a reply from a DATA command [5m, 2m].                                                                                                                                                                                                                                                                                                                                                                            |
| ident-initial           | The time-out for opening .forward and :include:files [60s, none].                                                                                                                                                                                                                                                                                                                                                             |
| hel0                    | The same as <b>connect</b> , except it applies only to the initial attempt to connect to a host for a given message [0, unspecified]. This period should be very short (a few seconds). Hosts that are well-connected and responsive will be serviced immediately. Hosts that are slow do not detain other deliveries in the initial delivery attempt.                                                                        |
| hoststatus              | The time-out waiting for a reply to an IDENT query [30s11, unspecified].                                                                                                                                                                                                                                                                                                                                                      |
| mail-misc               | The wait for the initial 220 greeting message [5m, 5m].                                                                                                                                                                                                                                                                                                                                                                       |
| quit                    | The wait for a reply from a HELO or EHLO command [5m, unspecified]. This may require a host name lookup, so five minutes is probably a reasonable minimum.                                                                                                                                                                                                                                                                    |
| rcpt-                   | The time that long status information about a host (for example, host down) will be cached before it is considered stale [30m, unspecified].                                                                                                                                                                                                                                                                                  |
| rset                    | The wait for a reply from a MAIL command [10m, 5m].                                                                                                                                                                                                                                                                                                                                                                           |
| resolver.retrans        | The wait for a reply from miscellaneous (but short) commands such as NOOP (no-operation) and VERB (go into verbose mode). [2m, unspecified].                                                                                                                                                                                                                                                                                  |
| resolver.retrans.first  | The wait for a reply from a QUIT command [2m, unspecified].                                                                                                                                                                                                                                                                                                                                                                   |
| resolver.retrans.normal | The wait for a reply from a RCPT command [1h, 5m]. This should be long because it could be pointing at a list that takes a long time to expand (see below).                                                                                                                                                                                                                                                                   |
| resolver.retry          | The wait for a reply from a RSET command [5m, unspecified].                                                                                                                                                                                                                                                                                                                                                                   |
| resolver.retry.first    | Sets resolver retransmission time interval in seconds. Sets both the <b>Timeout.resolver.retrans.first</b> and <b>Timeout.resolver.retrans.normal</b> .                                                                                                                                                                                                                                                                       |
| resolver.retry.normal   | Sets resolver retransmission time interval in seconds for the first attempt to deliver a message.                                                                                                                                                                                                                                                                                                                             |
| starttls                | Sets the retransmission time interval in seconds for all resolver lookups except for the first delivery attempt.                                                                                                                                                                                                                                                                                                              |
|                         | Sets the number of attempts to retransmit a resolver query. Sets both <b>Timeout.resolver.retry.first</b> and <b>Timeout.resolver.retry.normal</b> .                                                                                                                                                                                                                                                                          |
|                         | Sets the number of attempts to retransmit a resolver query for the first delivery attempt.                                                                                                                                                                                                                                                                                                                                    |
|                         | Sets the number of attempts to retransmit a resolver query for all resolver lookups except the first delivery attempt.                                                                                                                                                                                                                                                                                                        |
|                         | The timeout for a reply to an SMTP STARTTLS command, and the TLS handshake [1h, unspecified].                                                                                                                                                                                                                                                                                                                                 |

For compatibility with old configuration files, if no suboption is specified, all the timeouts marked with - are set to the indicated value.

## Message Timeouts

After sitting in the queue for a few days, a message will time out. This is to ensure that at least the sender is aware of the inability to send a message. The time-out is typically set to five days. It is sometimes considered convenient to also send a warning message if the message is in the queue longer than a few hours (assuming you normally have good connectivity; if your messages normally took several hours to send, you would not want to do this because it would not be an unusual event). These timeouts are set using the Timeout.queuereturn and Timeout.queuewarn options in the configuration file (previously both were set using the T option).

Because these options are global and you cannot know how long another host outside your domain will be down, a five-day time-out is recommended. This allows a recipient to fix the problem even if it occurs at the beginning of a long weekend. RFC 1123 section 5.3.1.1 says that this parameter should be "at least 4-5 days".

The Timeout.queuewarn value can be piggybacked on the T option by indicating a time after which a warning message should be sent; the two timeouts are separated by a slash. For example, the line:

```
OT5d/4h
```

causes e-mail to fail after five days, but a warning message will be sent after four hours. This should be large enough that the message will have been tried several times.

### Queue interval

The argument to the -q flag specifies how often a subdaemon will run the queue. This is typically set to between fifteen minutes and one hour. RFC 1123, section 5.3.1.1 recommends this be at least 30 minutes.

### Forking During Queue Runs

By setting the ForkEachJob (Y) option, **sendmail** will fork before each individual message while running the queue. This will prevent **sendmail** from consuming large amounts of memory, so it may be useful in memory-poor environments. However, if the ForkEachJob option is not set, **sendmail** will keep track of hosts that are down during a queue run, which can improve performance dramatically.

If the ForkEachJob option is set, **sendmail** cannot use connection caching.

### Queue Priorities

Every message is assigned a priority when it is first instantiated, consisting of the message size (in bytes) offset by the message class (which is determined from the Precedence: header) times the "work class factor" and the number of recipients times the "work recipient factor." The priority is used to order the queue. Higher numbers for the priority mean that the message will be processed later when running the queue.

The message size is included so that large messages are penalized relative to small messages. The message class allows users to send "high priority" messages by including a "Precedence:" field in their message; the value of this field is looked up in the P lines of the configuration file. Because the number of recipients affects the amount of load a message presents to the system, this is also included into the priority.

The recipient and class factors can be set in the configuration file using the RecipientFactor (y) and ClassFactor (z) options respectively. They default to 30000 (for the recipient factor) and 1800 (for the class factor). The initial priority is:

```
pri = msgsize - (class times bold ClassFactor) + (nrcpt times bold
RecipientFactor)
```

(Remember that higher values for this parameter actually mean that the job will be treated with lower priority.)

The priority of a job can also be adjusted each time it is processed (that is, each time an attempt is made to deliver it) using the "work time factor," set by the `RetryFactor(Z)` option. This is added to the priority, so it normally decreases the precedence of the job, on the grounds that jobs that have failed many times will tend to fail again in the future. The `RetryFactor` option defaults to 90000.

### Load Limiting

**Sendmail** can be asked to queue (but not deliver) mail if the system load average gets too high using the `QueueLA(x)` option. When the load average exceeds the value of the `QueueLA` option, the delivery mode is set to **q** (queue only) if the `QueueFactor(q)` option divided by the difference in the current load average and the `QueueLA` option plus one exceeds the priority of the message; that is, the message is queued if:

```
pri > { bold QueueFactor } over { LA - { bold QueueLA } + 1 }
```

The `QueueFactor` option defaults to 600000, so each point of load average is worth 600000 priority points (as described above).

For drastic cases, the `RefuseLA(X)` option defines a load average at which **sendmail** will refuse to accept network connections. Locally generated mail (including incoming UUCP mail) is still accepted.

### Delivery Mode

There are a number of delivery modes that **sendmail** can operate in, set by the `DeliveryMode(d)` configuration option. These modes specify how quickly mail will be delivered. Legal modes are:

| Delivery Mode | Definition                                |
|---------------|-------------------------------------------|
| i             | Deliver interactively (synchronously)     |
| b             | Deliver in background (asynchronously)    |
| q             | Queue only (do not deliver)               |
| d             | Defer delivery attempts (do not deliver). |

There are trade-offs. Mode **i** gives the sender the quickest feedback, but may slow down some mailers and is hardly ever necessary. Mode **b** delivers promptly, but can cause large numbers of processes if you have a mailer that takes a long time to deliver a message. Mode **q** minimizes the load on your machine, but means that delivery may be delayed for up to the queue interval. Mode **d** is identical to mode **q** except that it also prevents all the early map lookups from working; it is intended for "dial on demand" sites where DNS lookups might be very expensive. Some simple error messages (for example, host unknown during the SMTP protocol) will be delayed using this mode. Mode **b** is the default.

If you run in mode **q** (queue only), **d** (defer), or **b** (deliver in background), **sendmail** will not expand aliases and follow `.forward` files upon initial receipt of the mail. This speeds up the response to `RCPT` commands. Mode **i** cannot be used by the SMTP server.

### Log Level

The level of logging can be set for **sendmail**. The default using a standard configuration table is level 9. The levels are as follows:

| Log Level | Definition                                                                                                                    |
|-----------|-------------------------------------------------------------------------------------------------------------------------------|
| 0         | Minimum logging.                                                                                                              |
| 1         | Serious system failures and potential security problems.                                                                      |
| 2         | Lost communications (network problems) and protocol failures.                                                                 |
| 3         | Other serious failures.                                                                                                       |
| 4         | Minor failures.                                                                                                               |
| 5         | Message collection statistics.                                                                                                |
| 6         | Creation of error messages, VRFY and EXPN commands.                                                                           |
| 7         | Delivery failures (for example, host or user unknown).                                                                        |
| 8         | Successful deliveries and alias database rebuilds.                                                                            |
| 9         | Messages being deferred (for example, due to a host being down).                                                              |
| 10        | Database expansion (alias, forward, and userdb lookups).                                                                      |
| 11        | NIS errors and end-of-job processing.                                                                                         |
| 12        | Logs all SMTP connections.                                                                                                    |
| 13        | Logs bad user shells, files with improper permissions, and other questionable situations.                                     |
| 14        | Logs refused connections.                                                                                                     |
| 15        | Log all incoming and outgoing SMTP commands.                                                                                  |
| 20        | Logs attempts to run locked queue files. These are not errors, but can be useful to note if your queue appears to be clogged. |
| 30        | Lost locks (only if using <b>lockf</b> instead of <b>flock</b> ).                                                             |

## File Modes

The modes used for files depend on what functionality you want and the level of security you require.

The database that **sendmail** actually uses is represented by the following file:

**/etc/mail/aliases.db**  
Berkeley DB database

The mode on these files should match the mode of **/etc/mail/aliases**. If **aliases** is writable and the files are not, users will be unable to reflect their desired changes through to the actual database. However, if **aliases** is read-only and DBM files are writable, a slightly sophisticated user can arrange to steal mail anyway.

If your DBM files are not writable, or you do not have auto-rebuild enabled (with the AutoRebuildAliases option), then you must be careful to reconstruct the alias database each time you change the text version:

**newaliases**

If this step is ignored or forgotten, any intended changes will be lost.

## Connection Caching

When processing the queue, **sendmail** will try to keep the last few open connections open to avoid startup and shutdown costs. This only applies to IPC connections.

When trying to open a connection, the cache is first searched. If an open connection is found, it is probed to see if it is still active by sending a **RSET** command. It is not an error if this fails; instead, the connection is closed and reopened.

Two parameters control the connection cache. The **ConnectionCacheSize** (k) option defines the number of simultaneous open connections that will be permitted. If it is set to zero, connections will be closed as quickly as possible. The default is one. This should be set as appropriate for your system size; it will limit the amount of system resources that **sendmail** will use during queue runs. Never set this higher than 4.

The **ConnectionCacheTimeout** (K) option specifies the maximum time that any cached connection will be permitted to idle. When the idle time exceeds this value, the connection is closed. This number should be small (under ten minutes) to prevent you from grabbing too many resources from other hosts. The default is five minutes.

### Name Server Access

If you want machine exchange (MX) support, you must be using Domain Name Services (DNS).

The **ResolverOptions**(I) option allows you to tweak name server options. The command line takes a series of flags as documented inresolver(3) (with the leading "RES\_" deleted). Each can be preceded by an optional `+' or `-' . For example, the line:

```
0 ResolverOptions=+AAONLY -DNSRCH
```

turns on the AAONLY (Accept Authoritative Answers only) and turns off the DNSRCH (search the domain path) options. Most resolver libraries default DNSRCH, DEFNAMES, and RECURSE flags on and all others off. You can also include "HasWildcardMX" to specify that there is a wildcard MX record matching your domain; this turns off MX matching when canonicalizing names, which can lead to inappropriate canonicalizations.

### Moving the Per-User Forward Files

Some sites mount each user's home directory from a local disk on their workstation, so that local access is fast. However, the result is that **.forward** file lookups are slow. In some cases, mail can even be delivered on machines inappropriately because of a file server being down. The performance can be especially bad if you run the automounter.

The **ForwardPath** (J) option allows you to set a path of forward files. For example, the config file line:

```
0 ForwardPath=/var/forward/$u:$z/.forward.$w
```

would first look for a file with the same name as the user's login in **/var/forward**. If that is not found (or is inaccessible), the file ".forward.machinename" in the user's home directory is searched.

If you create a directory such as **/var/forward**, it should be mode 1777 (that is, the sticky bit should be set). Users should create the files mode 644.

### Free Space

On systems that have one of the system calls in the statfs(2) family (including **statvfs** and **ustat**), you can specify a minimum number of free blocks on the queue file system using the **MinFreeBlocks** (b) option. If there are fewer than the indicated number of blocks free on the filesystem on which the queue is mounted, the SMTP server will reject mail with the 452 error code. This invites the SMTP client to try again later.

**Attention:** Be careful not to set this option too high; it can cause rejection of e-mail when that mail would be processed without difficulty.

### Maximum Message Size

To avoid overflowing your system with a large message, the **MaxMessageSize** option can set an absolute limit on the size of any one message. This will be advertised in the ESMTP dialogue and checked during message collection.

### Privacy Flags

The PrivacyOptions (**p**) option allows you to set certain "privacy" flags. Actually, many of them do not give you any extra privacy, rather just insisting that client SMTP servers use the HELO command before using certain commands or adding extra headers to indicate possible security violations.

The option takes a series of flag names; the final privacy is the inclusive or of those flags. For example:

```
0 PrivacyOptions=needmailhelo, noexpn
```

insists that the HELO or EHLO command be used before a MAIL command is accepted and disables the EXPN command.

The flags are detailed in RFC 1123 S 5.1.6.

### Send to Me Too

Normally, **sendmail** deletes the (envelope) sender from any list expansions. For example, if "linda" sends to a list that contains "linda" as one of the members, she will not get a copy of the message. If the **-m** (me too) command line flag, or if the MeToo (**m**) option is set in the configuration file, this behavior is suppressed.

### C and F — Define Classes

Classes of phrases may be defined to match on the left hand side of rewrite rules, where a "phrase" is a sequence of characters that do not contain space characters. For example, a class of all local names for this site might be created so that attempts to send to oneself can be eliminated. These can either be defined directly in the configuration file or read in from another file. Classes are named as a single letter or a word in {braces}. Class names beginning with lowercase letters and special characters are reserved for system use. Classes defined in config files may be given names from the set of uppercase letters for short names or beginning with an uppercase letter for long names.

```
Ccphrase1 phrase2...
Fcfile
```

The first form defines the class c to match any of the named words. It is permissible to split them among multiple lines; for example, the two forms:

```
CHmonet ucbmonet
```

and

```
CHmonet
CHucbmonet
```

are equivalent. The "F" form reads the elements of the class c from the named file.

Elements of classes can be accessed in rules using **\$=** or **\$~**. The **\$~** (match entries not in class) only matches a single word; multi-word entries in the class are ignored in this context.

The class **\$=w** is set to be the set of all names this host is known by. This can be used to match local host names.

The class **\$=k** is set to be the same as **\$k**, that is, the UUCP node name.

The class **\$=m** is set to the set of domains by which this host is known, initially just **\$m**.

The class **\$=t** is set to the set of trusted users by the T configuration line. If you want to read trusted users from a file, use **Ft/file/name**.

The class **\$=n** can be set to the set of MIME body types that can never be eight to seven bit encoded. It defaults to "multipart/signed". Message types "message/\*" and "multipart/\*" are never encoded directly.

Multipart messages are always handled recursively. The handling of message/\* messages are controlled by class \$=s. The class \$=e contains the Content-Transfer-Encodings that can be 8->7 bit encoded. It is predefined to contain "7bit", "8bit", and "binary". The class \$=s contains the set of subtypes of message that can be treated recursively. By default it contains only "rfc822". Other "message/\*" types cannot be 8->7 bit encoded. If a message containing eight-bit data is sent to a seven-bit host, and that message cannot be encoded into seven bits, it will be stripped to 7 bits.

The three classes \$=U, \$=Y, and \$=Z are defined to describe the hosts requiring the use of a uucp mailer. Specifically, \$=U should contain all hosts requiring the uucp-old mailer. \$=Y should contain all hosts requiring the uucp-new mailer. Finally, \$=Z should contain all hosts requiring the uucp-uudom mailer. Each uucp host should belong to one of these classes.

**Sendmail** can be compiled to allow a `scanf(3)` string on the F line. This lets you do simplistic parsing of text files. For example, to read all the user names in your system `/etc/passwd` file into a class, use:

`FL/etc/passwd %[:]`

which reads every line up to the first colon.

### Changing the Host Name

**Cw** contains all the possible names for the local host. It defines aliases. **Cw** specifies the name and all aliases for your host system. If your system uses different names for two different network connections, enter both names as part of the host name class. If you do not define both names, mail sent to the undefined name is returned to the sender.

`CwCw alias aliasn...`

By default, the **sendmail** command reads what has been set with the **hostname** command and uses it to initialize the host and domain name macros and classes. Change the configuration file macros only if you want the **sendmail** host and domain names to be different from those set by the **hostname** command.

To change the host name:

1. Enter the command:

`vi /etc/mail/sendmail.cf`

2. Find the lines beginning with Dj and Dw. Dj and Dw override the host and domain names set with "hostname".
3. Replace Dj and Dw with the new hostname information. For example, if your hostname is `brown.newyork.abc.com`, and you have one alias, `brown2`, enter:
4. Save the file and exit the editor.

### Creating a Class Using a File

To define a class whose members are listed in an external file (one member per line), use a control line that begins with the letter F. The syntax for the F class definition is:

`FClass FileName [Format]`

**Class** is the name of the class that matches any of the words listed in **FileName**. **FileName** is the full path name of file (for convenience, you may wish to put the file in the `/etc/mail` directory). **Format** is an optional **scanf** subroutine format specifier that indicates the format of the elements of the class in **FileName**. The **Format** specifier can contain only one conversion specification.

## M — Define Mailer

Programs and interfaces to mailers are defined in this line. The format is:

`Mname, {field=value}*`

where name is the name of the mailer (used internally only) and the "field=name" pairs define attributes of the mailer. Fields are:

| Field              | Description                                        |
|--------------------|----------------------------------------------------|
| <b>Path</b>        | The path name of the mailer                        |
| <b>Flags</b>       | Special flags for this mailer                      |
| <b>Sender</b>      | Rewrite set(s) for sender addresses                |
| <b>Recipient</b>   | Rewrite set(s) for recipient addresses             |
| <b>Argv</b>        | An argument vector to pass to this mailer          |
| <b>Eol</b>         | The end-of-line string for this mail               |
| <b>Maxsize</b>     | The maximum message length to this mailer          |
| <b>maxmessages</b> | The maximum message delivers per connection        |
| <b>Linelimit</b>   | The maximum line length in the message body        |
| <b>Directory</b>   | The working directory for the mailer               |
| <b>Userid</b>      | The default user and group ID to run               |
| <b>Nice</b>        | The nice(2) increment for the mailer               |
| <b>Charset</b>     | The default character set for 8-bit characters     |
| <b>Type</b>        | The MTS type information (used for error messages) |
| <b>Wait</b>        | The maximum time to wait for the mailer            |
| /                  | The root directory for the mailer                  |
| <b>Queuegroup</b>  | The default queue group for the mailer.            |

Only the first character of the field name is checked.

The flags in the following list may be set in the mailer description. Any other flags may be used freely to conditionally assign headers to messages destined for particular mailers. Flags marked with - are not interpreted by the **sendmail** binary; these are conventionally used to correlate to the flags portion of the H line. Flags marked with = apply to the mailers for the sender address rather than the usual recipient mailers.

| Flag | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| a    | Run Extended SMTP (ESMTP) protocol (defined in RFCs 1651, 1652, and 1653). This flag defaults on if the SMTP greeting message includes the word "ESMTP".                                                                                                                                                                                                                                                                                                             |
| A    | Look up the user part of the address in the alias database. Normally this is only set for local mailers.                                                                                                                                                                                                                                                                                                                                                             |
| b    | Force a blank line on the end of a message. This is intended to work around some versions of /bin/mail that require a blank line, but do not provide it themselves. It would not normally be used on network mail.                                                                                                                                                                                                                                                   |
| c    | Do not include comments in addresses. This should only be used if you have to work around a remote mailer that gets confused by comments. This strips addresses of the form "Phrase <address>" or "address (Comment)" down to just "address".                                                                                                                                                                                                                        |
| C=   | If mail is received from a mailer with this flag set, any addresses in the header that do not have an at sign ("@") after being rewritten by ruleset three will have the "@domain" clause from the sender envelope address tacked on. This allows mail with headers of the form:<br><br>From: usera@hosta<br>To: userb@hostb, userc<br><br>to be rewritten automatically (although <i>not</i> reliably) as:<br><br>From: usera@hosta<br>To: userb@hostb, userc@hosta |
| d    | Do not include angle brackets around route-address syntax addresses. This is useful on mailers that are going to pass addresses to a shell that might interpret angle brackets as I/O redirection.                                                                                                                                                                                                                                                                   |
| D-   | This mailer wants a "Date:" header line.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| e    | This mailer is expensive to connect to, so try to avoid connecting normally. Any necessary connection will occur during a queue run.                                                                                                                                                                                                                                                                                                                                 |
| E    | Escape lines beginning with "From" in the message with a '>' sign.                                                                                                                                                                                                                                                                                                                                                                                                   |
| f    | The mailer wants a -f from flag, but only if this is a network forward operation (that is, the mailer will give an error if the executing user does not have special permissions).                                                                                                                                                                                                                                                                                   |
| F-   | This mailer wants a "From:" header line.                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Flag | Description                                                                                                                                                                                                                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| g    | Normally, <b>sendmail</b> sends internally generated error messages using the null return address as required by RFC 1123. However, some mailers do not accept a null return address. If necessary, you can set the g flag to prevent <b>sendmail</b> from obeying the standards; error messages will be sent as from the MAILER-DAEMON (actually, the value of the \$n macro).                                           |
| h    | Uppercase should be preserved in host names for this mailer.                                                                                                                                                                                                                                                                                                                                                              |

| I    | This mailer will be speaking SMTP to another <b>sendmail</b> , as such it can use special protocol features. This option is not required (that is, if this option is omitted the transmission will still operate successfully, although perhaps not as efficiently as possible).                                                                                                                                          |
| j    | Do User Database rewriting on recipients as well as senders.                                                                                                                                                                                                                                                                                                                                                              |
| k    | Normally when <b>sendmail</b> connects to a host via SMTP, it checks to make sure that this is not accidentally the same host name as might happen if <b>sendmail</b> is misconfigured or if a long-haul network interface is set in loopback mode. This flag disables the loopback check. It should only be used under very unusual circumstances.                                                                       |
| K    | Currently unimplemented. Reserved for chunking.                                                                                                                                                                                                                                                                                                                                                                           |
| l    | This mailer is local (that is, final delivery will be performed).                                                                                                                                                                                                                                                                                                                                                         |
| L    | Limit the line lengths as specified in RFC821. This deprecated option should be replaced by the L= mail declaration. For historic reasons, the L flag also sets the 7 flag.                                                                                                                                                                                                                                               |
| m    | This mailer can send to multiple users on the same host in one transaction. When a \$u macro occurs in the argy part of the mailer definition, that field will be repeated as necessary for all qualifying users.                                                                                                                                                                                                         |
| M-   | This mailer wants a "Message-Id:" header line.                                                                                                                                                                                                                                                                                                                                                                            |
| n    | Do not insert a UNIX-style "From" line on the front of the message.                                                                                                                                                                                                                                                                                                                                                       |
| o    | Always run as the owner of the recipient mailbox. Normally <b>sendmail</b> runs as the sender for locally generated mail or as "daemon" (actually, the user specified in the u option) when delivering network mail. The normal behavior is required by most local mailers, which will not allow the envelope sender address to be set unless the mailer is running as daemon. This flag is ignored if the S flag is set. |
| p    | Use the route-addr style reverse-path in the SMTP "MAIL FROM:" command rather than just the return address; although this is required in RFC821 section 3.1, many hosts do not process reverse-paths properly. Reverse-paths are officially discouraged by RFC 1123.                                                                                                                                                      |
| P-   | This mailer wants a "Return-Path:" line.                                                                                                                                                                                                                                                                                                                                                                                  |
| q    | When an address that resolves to this mailer is verified (SMTP VRFY command), generate 250 responses instead of 252 responses. This will imply that the address is local.                                                                                                                                                                                                                                                 |

| Item | Description                                                                                                                                                                                                                                                                                                                                                                                         |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| r    | Same as f, but sends an -r flag.                                                                                                                                                                                                                                                                                                                                                                    |
| R    | Open SMTP connections from a "secure" port. Secure ports are not secure except on UNIX machines, so it is unclear that this adds anything.                                                                                                                                                                                                                                                          |
| s    | Strip quote characters (" and \") off the address before calling the mailer.                                                                                                                                                                                                                                                                                                                        |
| S    | Do not reset the userid before calling the mailer. This would be used in a secure environment where <b>sendmail</b> ran as root. This could be used to avoid forged addresses. If the U= field is also specified, this flag causes the userid to always be set to that user and group (instead of leaving it as root).                                                                              |
| u    | Uppercase should be preserved in user names for this mailer.                                                                                                                                                                                                                                                                                                                                        |
| U    | This mailer wants UUCP-style "From" lines with the "remote from <host>" on the end.                                                                                                                                                                                                                                                                                                                 |
| w    | The user must have a valid account on this machine (getpwnam must succeed). If not, the mail is bounced. This is required to get ".forward" capability.                                                                                                                                                                                                                                             |
| x-   | This mailer wants a "Full-Name:" header line.                                                                                                                                                                                                                                                                                                                                                       |
| X    | This mailer wants to use the hidden dot algorithm as specified in RFC821; basically, any line beginning with a dot will have an extra dot prepended (to be stripped at the other end). This ensures that lines in the message containing a dot will not terminate the message prematurely.                                                                                                          |
| z    | Run Local Mail Transfer Protocol (LMTP) between <b>sendmail</b> and the local mailer. This is a variant on SMTP defined in RFC 2033 that is specially designed for delivery to a local mailbox.                                                                                                                                                                                                     |
| 0    | Do not look up Mx records for hosts via SMTP.                                                                                                                                                                                                                                                                                                                                                       |
| 3    | Extend the list of characters converted to =XX notation when converting to Quoted-Printable to include those that do not map cleanly between ASCII and EBCDIC. Useful if you have IBM mainframes on site.                                                                                                                                                                                           |
| 5    | If no aliases are found for this address, pass the address through ruleset 5 for possible alternate resolution. This is intended to forward the mail to an alternate delivery spot.                                                                                                                                                                                                                 |
| 6    | Strip headers to seven bits.                                                                                                                                                                                                                                                                                                                                                                        |
| 7    | Strip all output to seven bits. This is the default if the L flag is set. Note that clearing this option is not sufficient to get full eight-bit data passed through <b>sendmail</b> . If the 7 option is set, this is essentially always set, because the eighth bit was stripped on input. Note that this option will only impact messages that did not have 8->7 bit MIME conversions performed. |

| Item | Description                                                                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8    | If set, it is acceptable to send eight bit data to this mailer; the usual attempt to do 8->7 bit MIME conversions will be bypassed.                                                   |
| 9    | If set, do limited 7->8 bit MIME conversions. These conversions are limited to text/plain data.                                                                                       |
| :    | Check addresses to see if they begin ":include:". If they do, convert them to the "*include*" mailer.                                                                                 |
|      | Check addresses to see if they begin with a ' '. If they do, convert them to the "prog" mailer.                                                                                       |
| /    | Check addresses to see if they begin with a '/'. If they do, convert them to the "*file*" mailer.                                                                                     |
| @    | Look up addresses in the user database.                                                                                                                                               |
| %    | Do not attempt delivery on initial recipient of a message or on queue runs unless the queued message is selected using one of the -qI/-qR/-qS queue run modifiers or an ETRN request. |

**Note:** Configuration files prior to level 6 assume the `A', `w', `5', `:', `|', `/', and `@' options on the mailer named "local".

The mailer with the special name "error" can be used to generate a user error. The (optional) host field is an exit status to be returned, and the user field is a message to be printed. The exit status may be numeric or one of the values USAGE, NOUSER, NOHOST, UNAVAILABLE, SOFTWARE, TEMPFAIL, PROTOCOL, or CONFIG to return the corresponding EX\_ exit code. For example, the entry:

```
$#error $@ NOHOST $: Host unknown in this domain
```

on the RHS of a rule will cause the specified error to be generated and the "Host unknown" exit status to be returned if the LHS matches. It is always available for use in O, S, and check\_ ... rulesets and it cannot be defined with M commands.

The mailer named "local" must be defined in every configuration file. This is used to deliver local mail, and is treated specially in several ways. Additionally, three other mailers named "prog", "\*file\*", and "\*include\*" may be defined to tune the delivery of messages to programs, files, and :include: lists respectively. They default to:

```
Mprog, P=/bin/sh, F=lsodq9, T=DNS/RFC822/X-Unix, A=sh -c $u
M*file*, P=[FILE], F=lsDFMPEuq9, T=DNS/RFC822/X-Unix, A=FILE $u
M*include*, P=/dev/null, F=su, A=INCLUDE $u
```

The Sender and Recipient rewrite sets may either be a simple ruleset ID or may be two IDs separated by a slash. If so, the first rewrite set is applied to envelope addresses, and the second is applied to headers. Setting any value to zero disables the corresponding mailer-specific rewriting.

The Directory field is a path of directories to try. For example, the definition D=\$z:/ tries to execute the recipient's home directory, but if that is not available, it tries to execute in the root of the filesystem. Use this on the **prog** mailer only, because some shells (e.g., **csh**) do not execute if they cannot read the home directory. Because the queue directory usually cannot be read by unauthorized users, **csh** scripts can fail if they are used as recipients.

The Userid field specifies the default user and group ID to run. It overrides the **DefaultUser** option q.v. If the **S** mailer flag is also specified, the user and group ID will run in all circumstances. Use the form *user:group* to set both the user and group ID. Either of these variables may be an integer or a symbolic name that is looked up in the **passwd** and **group** files respectively.

The Charset field is used when converting a message to MIME. It is the character set used in the Content-Type: header. If it is not set, the **DefaultCharset** option is used. If the **DefaultCharset** is not set, the value unknown-8bit is used. The **Charset** field applies to the sender's mailer; not the recipient's mailer. For example: if the envelope sender address is on the local network and the recipient is on an external network, the character set is set from the Charset= field for the local network mailer, not the external network mailer.

The Type field sets the type of information used in MIME error messages (as defined by RFC 1984). It contains three values that are separated by slashes: the MTA type (a description of how hosts are named),

address type (a description of e-mail addresses), and diagnostic type (a description of error diagnostic codes). Each must be a registered value or begin with X-. The default is dns/rfc822/smtp.

### Mailer Specifications Examples

1. To specify a local delivery mailer enter:

```
Mlocal, P=/usr/bin/bellmail, F=lsDFMmn, S=10, R=20, A=mail $u
```

The mailer is called `local`. Its path name is `/usr/bin/bellmail`. The mailer uses the following flags:

| Item | Description                                                              |
|------|--------------------------------------------------------------------------|
| l    | Specifies local delivery.                                                |
| s    | Strips quotation marks from addresses.                                   |
| DFM  | Requires Date:, From:, and Message-ID: fields.                           |
| m    | Delivers to multiple users.                                              |
| n    | Does not need an operating system From line at the start of the message. |

Rule set 10 should be applied to sender addresses in the message. Rule set 20 should be applied to recipient addresses. Additional information sent to the mailer in the A field is the word `mail` and words containing the recipient's name.

### H — Define Header

The format of the header lines that `sendmail` inserts into the message are defined by the H line. The syntax of this line is one of the following:

`H1name:1h1template`

`H[?mflags?]name: h1template`

`H[$macro?name: h1template`

Continuation lines in this spec are reflected directly into the outgoing message. The htemplate is macro expanded before insertion into the message. If the mflags (surrounded by question marks) are specified, at least one of the specified flags must be stated in the mailer definition for this header to be automatically output. If one of these headers is in the input, it is reflected to the output regardless of these flags.

Some headers have special semantics that will be described later.

A secondary syntax allows validation of headers as they being read. To enable validation, use:

`HHeader: $>Ruleset`  
`HHeader: $>+Ruleset`

The indicated Ruleset is called for the specified Header. Like other `check_*` rulesets, it can return `$#error` to reject the message or `$#discard` to discard the message. The header is treated as a structured field, so comments (in parentheses) are deleted before processing, unless the second form `$>+` is used.

For example, the following configuration lines:

```
HMessage-Id: $>CheckMessageId

SCheckMessageId
R<$>+$> $@OK
R$* $#error $: Illegal Message-Id header
```

would refuse any message header that had a Message-Id: header of any of the following forms:

```
Message-Id: <>
Message-Id: some text
Message-Id: <legal test@domain> extra text
```

## Message Headings in the sendmail.cf File

Lines in the configuration file that begin with a capital letter *H*, define the format of the headers used in messages. The format of the *H* command is:

Lines in the configuration file that begin with a capital letter *H*, define the format of the headers used in messages. The format of the *H* control line is:

*H[?MailerFlags?]FieldName: Content*

The variable parameters are defined as:

| Parameter   | Definition                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MailerFlags | Determines whether the <i>H</i> line is used. This parameter is optional. If you supply this parameter, surround it with ? (question marks). If the mailer requires the field defined by this control line (as indicated in the mailer definition's flags field), then the <i>H</i> control line is included when formatting the heading. Otherwise, the <i>H</i> control line is ignored. |
| FieldName   | Contains the text displayed as the name of the field in the heading information. Typical field names include From:, To:, and Subject:..                                                                                                                                                                                                                                                    |
| Content     | Defines the information that is displayed following the field name. Usually macros specify this information.                                                                                                                                                                                                                                                                               |

These example lines are from a typical /etc/mail/sendmail.cf file:

| Example                                                            | Meaning                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>H?P?Return-Path: &lt;\$g&gt;</i>                                | Defines a field called Return-Path that displays the content of the \$g macro (sender address relative to the recipient). The ?P? portion indicates this line is only used if the mailer uses the P flag (the mailer requires a Return-Path line). The header is generated only if the mailer has the indicated flag. If the header appears in the input message, it is passed through unchanged.                                                                                                                                                                                                                                                                                         |
| <i>HReceived: \$?sfrom \$s \$.by<br/>\$j (\$v/\$Z) id \$i; \$b</i> | Defines a field called Received. This field includes:<br><br><i>\$?sfrom \$s \$.</i> Displays the text from followed by the content of the \$s macro if an s macro is defined (sender's host name).<br><i>by \$j</i> Displays the text by followed by the content of the \$j macro (official name for a specific location).<br><i>(\$v/\$Z)</i> Displays the version of the sendmail command (\$v) and the version of the /etc/mail/sendmail.cf file (\$Z), set off by parentheses and separated by a slash.<br><i>id \$i;</i> Displays the text id followed by the content of the \$i macro (mail-queue ID of the message) and a ; (semicolon).<br><i>\$b</i> Displays the current date. |

## O — Set Option

There are several global options that can be set from a configuration file. The syntax of this line is:

**0** *option=value*

This sets option *equal* to *value*. The options supported are listed in the following table.

| Option                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AliasFile</b> = <i>spec, spec, ...</i> | Specify possible alias file(s). Each spec should be in the format <i>class:: file</i> where <i>class::</i> is optional and defaults to <b>implicit</b> if not included. Depending on how <b>sendmail</b> is compiled, valid classes are:<br><br><b>implicit</b> search through a compiled-in list of alias file types, for back compatibility<br><b>hash</b> if NEWDB is specified<br><b>dbm</b> if NDBM is specified<br><b>stab</b> Internal symbol table. Not normally used unless there is no other database lookup<br><b>nis</b> if NIS is specified<br><br>If a list of specs are provided, <b>sendmail</b> searches them in order.                                                                                                                                                        |
| <b>AliasWait</b> = <i>time-out</i>        | Waits up to <i>time-out</i> (units default to minutes) for an @:@ entry to exist in the alias database before starting up. If it does not appear in the <i>time-out</i> interval and the <b>AutoRebuildAliases</b> option is also set, rebuild the database. Otherwise, issue a warning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>AllowBogusHELO</b>                     | Allows <b>HELO</b> SMTP commands that do not include a host name. Setting this violates RFC 1123 section 5.2.5, but is necessary to interoperate with several SMTP clients. If there is a value, it is still checked for legitimacy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>BlankSub</b> = <i>c</i>                | Sets the blank substitution character to <i>c</i> . Unquoted spaces in addresses are replaced by this character. If not defined, it defaults to a space and no replacement is made.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>CACERTPath</b>                         | Path to directory with certificates of CAs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>CACERTFile</b>                         | File containing one CA certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>CheckAliases</b>                       | Validate the RHS of aliases when rebuilding the alias database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>CheckpointInterval</b> = <i>N</i>      | Defines the queue checkpoint interval to every <i>N</i> addresses sent. If not specified, the default is 10. If your system crashes during delivery to a large list, this prevents retransmission to any but the last recipients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ClassFactor</b> = <i>fact</i>          | The indicated <i>factor</i> is multiplied by the message class and subtracted from the priority. The message class is determined by the <b>Precedence:</b> field in the user header and the <b>P</b> lines in the configuration file. Messages with a higher <b>Priority:</b> will be favored. If not specified, the defaults is 1800.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ClientCertFile</b>                     | The file containing the certificate of the client. This certificate is used when <b>sendmail</b> acts as client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ClientPortOptions</b> = <i>options</i> | Sets client SMTP options. The options are <i>key=value</i> pairs separated by commas. Known keys are:<br><br><b>Port</b> Name/number of source port for connection. Default is any free port.<br><b>Addr</b> Address mask. Default is INADDR_ANY. Can be a numeric address in dot notation or a network name.<br><b>Family</b> Address family. Default is INET.<br><b>SndBufSize</b> Size of TCP send buffer.<br><b>RcvBufSize</b> Size of TCP receive buffer.<br><b>Modifier</b> Flags for the daemon. Can be the following character:<br><b>h</b> Use name of interface for <b>HELO</b> command<br>If <b>h</b> is set, the name corresponding to the outgoing interface address (whether chosen via the <i>Connection</i> parameter or the default) is used for the <b>HELO/EHLO</b> command. |
| <b>ClientKeyFile</b>                      | The file containing the private key belonging to the client certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Option                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ColonOkInAddr</b>                              | <p>If set, colons are acceptable in e-mail addresses, for example:<br/> <i>host:user</i></p> <p>If not set, colons indicate the beginning of a RFC 822 group construct, illustrated below:<br/> <i>groupname: member1, member2, ... memberN;</i></p> <p>Doubled colons are always acceptable, such as in<br/> <i>nodename::user</i></p> <p>and proper routeaddr nesting is understood, for example:<br/> <i>&lt;@relay:user@host&gt;</i></p> <p>This option defaults to on if the configuration version level is less than 6, for backward compatibility. However, it must be set to off for full compatibility with RFC 822.</p> |
| <b>ConnectionCacheSize=N</b>                      | <p><i>N</i> is the maximum number of open connections that will be cached at a time. If not specified, the default is 1. This delays closing the current connection until either this invocation of <b>sendmail</b> connects to another host or it terminates. Setting it to 0 causes connections to closed immediately. Because this consumes file descriptors, the connection cache should be kept small: 4 is a practical maximum.</p>                                                                                                                                                                                         |
| <b>ConnectionCacheTimeout</b><br><i>=time-out</i> | <p><i>Timeout</i> is the maximum amount of time a cached connection will be permitted to be idle. If this time is exceeded, the connection is immediately closed. This value should be small: 10 minutes is a practical maximum; the default is 5 minutes. Before <b>sendmail</b> uses a cached connection, it always sends a <b>RSET</b> command to check the connection. If this fails, it reopens the connection. This keeps your end from failing if the other end times out.</p>                                                                                                                                             |
| <b>ConnectOnlyTo=address</b>                      | Can be used to override the connection address for testing purposes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>ConnectionRateThrottle=N</b>                   | If set, allows no more than <i>N</i> incoming daemon connections in a one second period. This is intended to flatten peaks and allow the load-average checking to cut in. If not specified, the default is 0 (no limits).                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ControlSocketName=name</b>                     | Defines the name of the control socket for daemon management. A running <b>sendmail</b> daemon can be controlled through this named socket. Available commands are: <b>help</b> , <b>restart</b> , <b>shutdown</b> , and <b>status</b> . The <b>status</b> command returns the current number of daemon children, the maximum number of daemon children, free disk space blocks of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket will be available.                                                                                                             |

| Option                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DaemonPortOptions</b> = <i>options</i> | <p>Set server SMTP options. Each instance of <b>DaemonPortOptions</b> leads to an additional incoming socket. The options are <i>key=value</i> pairs. Known keys are:</p> <ul style="list-style-type: none"> <li><b>Name</b> User-definable name for the daemon. Default is <b>Daemon#</b>. Is used for error messages and logging.</li> <li>To be able to send mail but not receive mail on a system, edit <code>/etc/mail/sendmail.cf</code>:</li> <pre># 0 DaemonPortOptions=Name=MTA 0 DaemonPortOptions=NAME=NoMTA4, Family=inet, Addr=127.0.0.1</pre> <li><b>Port</b> Name/number of listening port. Default is <code>smtp</code>.</li> <li><b>Addr</b> Address mask. Default is <code>INADDR_ANY</code>. This may be a numeric address in dot notation or a network name.</li> <li><b>Family</b> Address family. Default is <code>INET</code> (IPv4). IPv6 systems that need to accept IPv6 connections, should add additional <code>Family=inet6</code> DaemonPort Options lines.</li> <li><b>Listen</b> Size of listen queue. Default is 10.</li> </ul> <p><b>Modifier</b></p> <p>Flags for the daemon. Can be a sequence, without delimiters, of the following characters:</p> <ul style="list-style-type: none"> <li><b>a</b> Always require authentication.</li> <li><b>b</b> Bind to interface through which mail has been received for the outgoing connection.<br/><b>Note:</b> Use the <b>b</b> flag only if outgoing mail can be routed through the incoming connection's interface to its destination. No attempt is made to catch problems that result from incorrectly configuring this parameter. It should only be used for virtual hosting where each virtual interface can connect to every possible location. The <b>b</b> flag can override the settings through <b>ClientPort Options</b>. In addition, <code>sendmail</code> will listen on a new socket for each occurrence of the <b>DaemonPortOptions</b> subcommand in a configuration file.</li> <li><b>c</b> Perform hostname canonicalization (.cf). Can change the default for hostname canonicalization in the <code>sendmail.cf</code> file. See the documentation for <b>FEATURE(nocanonify)</b> in the <code>/user/samples/tcpip/sendmail/README</code> file.</li> <li><b>f</b> Require fully qualified hostname (.cf). Cannot use addresses in the form <code>user@host</code> unless they are directly submitted.</li> <li><b>u</b> Allow unqualified addresses (.cf) (including sender addresses).</li> <li><b>C</b> Do not perform hostname canonicalization. Can change the default for hostname canonicalization in the <code>sendmail.cf</code> file. See the documentation for <b>FEATURE(nocanonify)</b> in the <code>/user/samples/tcpip/sendmail/README</code> file.</li> <li><b>E</b> Do not allow ETRN (see RFC 2476). One way to specify a message submission agent (MSA) that always require authentication is:<br/>0 DeamonPortOptions=Name=MSA,Port=587,M=Ea</li> </ul> <p>Modifiers marked with (.cf) are effective only when used in the standard configuration file (available through <code>\$(daemon_flags)</code>) and cannot be used from the command line.</p> |

| <b>refuseLA</b>                                | RefuseLA per daemon.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>delayLA</b>                                 | DelayLA per daemon.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>queueLA</b>                                 | QueueLA per daemon.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DefaultAuthInfo</b>                         | Filename that contains default authentication information for outgoing connections. This file must contain the user ID, authorization ID, password (plain text), and the realm to use on separate lines and must be readable only by root (or the trusted user). If no realm is specified, \$j is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DefaultCharSet=</b> <i>charset</i>          | When a message that has 8-bit characters, but is not in MIME format, is converted to MIME (see the EightBitMode option) a character set must be included in the Content-Type: header. This character set is normally set from the Charset= field of the mailer descriptor. If that is not set, the value of this option is used. If this option is not set, the value unknown-8bit is used.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DataFileBufferSize=</b> <i>threshold</i>    | Sets <i>threshold</i> in bytes before a memory-based queue data file becomes disk-based. The default is 4096 bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DeadLetterDrop=</b> <i>file</i>             | Defines the location of the systemwide <b>dead.letter</b> file, formerly hardcoded to /usr/tmp/dead.letter. If this option is not set, <b>sendmail</b> will not attempt to save to a systemwide <b>dead.letter</b> file in the event it cannot bounce the mail to the user or postmaster. Instead, it will rename the <b>qf</b> file.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DefaultUser=</b> <i>user:group</i>          | Set the default user ID for mailers to <i>user:group</i> . If <i>group</i> is omitted and <i>user</i> is a user name (as opposed to a numeric user ID) the default group listed in the /etc/passwd file for that user is used as the default group. Both <i>user</i> and <i>group</i> may be numeric. Mailers without the S flag in the mailer definition will run as this user. When not specified, the default is 1:1. The value can also be given as a symbolic user name.                                                                                                                                                                                                                                                                                      |
| <b>DeliveryMode=</b> <i>x</i>                  | Deliver in mode <i>x</i> . Legal modes are:<br><ul style="list-style-type: none"> <li><b>i</b> Deliver interactively (synchronously).</li> <li><b>b</b> Deliver in background (asynchronously).</li> <li><b>q</b> Just queue the message (deliver during queue run).</li> <li><b>d</b> Defer delivery and all map lookups (deliver during queue run).</li> </ul> Defaults to <b>b</b> if no option is specified, <b>i</b> if it is specified but given no argument (for example, <b>Od</b> is equivalent to <b>Od<i>i</i></b> ). The <b>-v</b> command line flag sets this to <b>i</b> .<br><b>Note:</b> For internal reasons, <b>i</b> does not work if a milter is enabled which can reject or delete recipients. In that case the mode is changed to <b>b</b> . |
| <b>DialDelay=</b> <i>sleepetime</i>            | Dial-on-demand network connections can see time-outs if a connection is opened before the call is set up. If this is set to an interval and a connection times out on the first connection being attempted, <b>sendmail</b> will sleep for this amount of time and try again. This should give your system time to establish the connection to your service provider. Units default to seconds, so <b>DialDelay=5</b> would use a five second delay. If not specified, the default is 0 (no retry).                                                                                                                                                                                                                                                                |

| Option                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DontBlameSendmail</b><br>=option,option,... | In order to avoid possible cracking attempts caused by world- and group-writable files and directories, <b>sendmail</b> does paranoid checking when opening most of its support files. However, if a system must run with a group-writable <i>/etc</i> directory, then this checking must be turned off. Note that turning off this checking will make your system more vulnerable to attack. The arguments are individual options that turn off checking: |
| <b>Safe</b>                                    | No special handling.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>AssumeSafeChown</b>                         | Assume that the <b>chown</b> call is restricted to root. Because some systems are set up to permit regular users to give away their files to other users on some file systems, <b>sendmail</b> often cannot assume that a given file was created by the owner, particularly when it is in a writable directory. You can set this flag if you know that file giveaway is restricted on your system.                                                         |
| <b>ClassFileInUnsafeDirPath</b>                | When reading class files (using the F line in the configuration file), allow files that are in unsafe directories.                                                                                                                                                                                                                                                                                                                                         |
| <b>DontWarnForwardFileInUnsafeDirPath</b>      | Prevent logging of unsafe directory path warnings for nonexistent forward files.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ErrorHeaderInUnsafeDirPath</b>              | Allow the file named in the <b>ErrorHeader</b> option to be in an unsafe directory.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>FileDeliveryToHardLink</b>                  | Allow delivery to files that are hard links.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>FileDeliveryToSymLink</b>                   | Allow delivery to files that are symbolic links.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ForwardFileInUnsafeDirPath</b>              | Allow .forward files in unsafe directories.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ForwardFileInUnsafeDirPathSafe</b>          | Allow .forward files that are in an unsafe directory to include references to program and files.                                                                                                                                                                                                                                                                                                                                                           |
| <b>ForwardFileInGroupWritableDirPath</b>       | Allow .forward files in group writable directories.                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>GroupWritableAliasFile</b>                  | Allow group-writable alias files.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>GroupWritableDirPathSafe</b>                | Change the definition of <i>unsafe directory</i> to consider group-writable directories to be safe. World-writable directories are always unsafe.                                                                                                                                                                                                                                                                                                          |
| <b>GroupWritableForwardFileSafe</b>            | Accept group-writable .forward files.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>GroupWritableIncludeFileSafe</b>            | Accept group-writable :include: files.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>HelpFileInUnsafeDirPath</b>                 | Allow the file named in the <b>HelpFile</b> option to be in an unsafe directory.                                                                                                                                                                                                                                                                                                                                                                           |
| <b>IncludeFileInUnsafeDirPath</b>              | Allow :include: files in unsafe directories.                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>IncludeFileInUnsafeDirPathSafe</b>       | Allow .forward files that are in an unsafe directory to include references to program and files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>IncludeFileInGroupWritableDirPath</b>    | Allow :include: files in group writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>InsufficientEntropy</b>                  | Try to use STARTTLS even if the PRGN for OpenSSL is not properly seeded despite the security problems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>LinkedAliasFileInWritableDir</b>         | Allow alias files that are links in a writable directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>LinkedClassFileInWritableDir</b>         | Allow class files that are links in writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>LinkedForwardFileInWritableDir</b>       | Allow .forward files that are links in writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>LinkedIncludeFileInWritableDir</b>       | Allow :include: files that are links in writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>LinkedMapInWritableDir</b>               | Allow map files that are links in writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>LinkedServiceSwitchFileInWritableDir</b> | Allow the service switch file to be a link even if the directory is writable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MapInUnsafeDirPath</b>                   | Allow maps (such as hash, btree, and dbm files) in unsafe directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>NonRootSafeAddr</b>                      | Do not mark file and program deliveries as unsafe if sendmail is not running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>RunProgramInUnsafeDirPath</b>            | Run programs that are in writable directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>RunWritableProgram</b>                   | Run programs that are group- or world-writable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TrustStickyBit</b>                       | Allow group- or world-writable directories if the sticky bit is set on the directory. Do not set this on systems which do not honor the sticky bit on directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>WorldWritableAliasFile</b>               | Accept world-writable alias files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>WriteMapToHardLink</b>                   | Allow writes to maps that are hard links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>WriteMapToSymLink</b>                    | Allow writes to maps that are symbolic links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>WriteStatsToHardLink</b>                 | Allow the status file to be a hard link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>WriteStatsToSymLink</b>                  | Allow the status file to be a symbolic link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Safe</b>                                 | is the default. The details of these flags are described above. Use of this option is not recommended.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>DontExpandCnames</b>                     | The standards say that all host addresses used in a mail message must be fully canonical. For example, if your host is named <b>Cruft.Foo.ORG</b> and also has an alias of <b>FTP.Foo.ORG</b> , the name <b>Cruft.Foo.ORG</b> must be used at all times. This is enforced during host name canonicalization (\$[ ... \$] lookups). If this option is set, the protocols will be ignored and the wrong name will be used. However, the IETF is moving toward changing this standard, so the behavior may become acceptable. Please note that hosts downstream may still rewrite the address to be the true canonical name. |

| Option                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DontInitGroups</b>                               | If set, <b>sendmail</b> will avoid using the <b>initgroups(3)</b> call. If you are running NIS, this causes a sequential scan of the <b>groupsbyname</b> map, which can cause your NIS server to be badly overloaded in a large domain. The cost of this is that the only group found for users will be their primary group (the one in the password file), which will make file access permissions somewhat more restrictive. Has no effect on systems that do not have group lists.                                                                                        |
| <b>DontProbeInterfaces</b>                          | <b>Sendmail</b> normally finds the names of all interfaces active on your machine when it starts up and adds their name to the <b>\$=w</b> class of known host aliases. If you have a large number of virtual interfaces or if your DNS inverse lookups are slow this can be time consuming. This option turns off that probing. However, you will need to be certain to include all variant names in the <b>\$=w</b> class by some other mechanism.                                                                                                                         |
| <b>DontPruneRoutes</b>                              | <b>Sendmail</b> tries to eliminate any unnecessary explicit routes when sending an error message (as discussed in RFC 1123 S 5.2.6). For example, when sending an error message to <b>&lt;@known1,@known2,@known3:user@unknown&gt;</b> , <b>sendmail</b> will strip off the <b>@known1,@known2</b> in order to make the route as direct as possible. However, if the <b>RR</b> option is set, this will be disabled, and the mail will be sent to the first address in the route, even if later addresses are known. This may be useful if you are caught behind a firewall. |
| <b>DoubleBounceAddress</b><br><i>=error-address</i> | If an error occurs when sending an error message, send the error report to the indicated address. This is termed a <i>double bounce</i> because it is an error bounce that occurs when trying to send another error bounce. The address is macro expanded at the time of delivery. If not set, it defaults to <b>postmaster</b> .                                                                                                                                                                                                                                            |

| Item                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EightBitMode</b> <i>=action</i>          | <p>Set handling of eight-bit data. There are two kinds of eight-bit data:</p> <ul style="list-style-type: none"> <li>• Data declared as eight-bit using the <b>BODY=8BITMIME</b> ESMTP declaration or the <b>-B8BITMIME</b> command line flag</li> <li>• Undeclared 8-bit data, which is input that just happens to be eight bits.</li> </ul> <p>There are three basic operations that can happen:</p> <ul style="list-style-type: none"> <li>• Undeclared 8-bit data can be automatically converted to 8BITMIME.</li> <li>• Undeclared 8-bit data can be passed as-is, without conversion to MIME.</li> <li>• Declared 8-bit data can be converted to 7-bits for transmission to a non-8BITMIME mailer.</li> </ul> <p>Possible actions are:</p> <ul style="list-style-type: none"> <li><b>s</b>      Reject undeclared 8-bit data (strict).</li> <li><b>m</b>      Convert undeclared 8-bit data to MIME (mime).</li> <li><b>p</b>      Pass undeclared 8-bit data (pass).</li> </ul> <p>In all cases properly declared 8BITMIME data will be converted to 7BIT as needed.</p> |
| <b>ErrorHeader</b> <i>=file-or-message</i>  | Prepend error messages with the indicated message. If it begins with a slash (/), it is assumed to be the pathname of a file containing a message, which is the recommended setting. Otherwise, it is a literal message. The error file might contain the name, e-mail address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or null, or if it names a file which does not exist or are not readable, no message is printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ErrorMode</b> <i>=x</i>                  | Dispose of errors using mode <i>x</i> . The values for <i>x</i> are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                                             | <ul style="list-style-type: none"> <li><b>p</b>      Print error messages (default).</li> <li><b>q</b>      No messages, just give exit status.</li> <li><b>m</b>      Mail back errors.</li> <li><b>w</b>      Write back errors (mail if user not logged in).</li> <li><b>e</b>      Mail back errors and give zero exit status always.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>.FallbackMXhost</b> <i>=fallbackhost</i> | If specified, the <i>fallbackhost</i> acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity. Messages which are undeliverable due to temporary address failures, such as in a DNS failure, also go to the FallBackMX host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FallBackSmartHost=hostname</b>      | If specified, the <b>FallBackSmartHost</b> is be used in a last-ditch effort for each host.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>FastSplit</b>                       | If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache.                                                                                                                                                                                                                                                                                                                                    |
| <b>ForkEachJob</b>                     | If set, deliver each job that is run from the queue in a separate process. Use this option if you are short of memory, because the default tends to consume considerable amounts of memory while the queue is being processed.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>ForwardPath=<i>path</i></b>         | Sets the path for searching for users' <b>.forward</b> files. The default is <b>\$z/.forward</b> . Some sites that use the automounter may prefer to change this to <b>/var/forward/\$u</b> to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons. <b>Sendmail</b> stops at the first file it can successfully and safely open. For example, <b>/var/forward/\$u:\$z/.forward</b>                                                                                                                                                                    |
|                                        | will search first in <b>/var/forward/username</b> and then in <b>~username/.forward</b> , but only if the first file does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>HelpFile=<i>file</i></b>            | Specifies the help file for SMTP. If no file name is specified, <b>helpfile</b> is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>HoldExpensive</b>                   | If an outgoing mailer is marked as being expensive, do not connect immediately. This requires that queueing be compiled in, because it will depend on a queue run process to actually send the mail.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>HostsFile=<i>path</i></b>           | Specifies the path to the hosts database, normally <b>/etc/hosts</b> . This option is only consulted when <b>sendmail</b> is canonicalizing addresses, and then only when <b>files</b> is in the <b>hosts</b> service switch entry. In particular, this file is never used when looking up host addresses; that is under the control of the system <b>gethostbyname(3)</b> routine.                                                                                                                                                                                                                                                 |
| <b>HostStatusDirectory=<i>path</i></b> | Sets the location of the long term host status information. When set, information about the status of hosts (such as if the host down or not accepting connections) will be shared between all <b>sendmail</b> processes. Normally, this information is only held within a single queue run. This option requires a connection cache of at least 1 to function. If the option begins with a leading <b>/</b> , it is an absolute pathname; otherwise, it is relative to the mail queue directory. A suggested value for sites desiring persistent host status is <b>.hoststat</b> , which is a subdirectory of the queue directory. |
| <b>IgnoreDots</b>                      | Ignore dots in incoming messages. This is always disabled when reading SMTP mail, and as a result, dots are always accepted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>LDAPDefaultSpec=<i>spec</i></b>     | Sets a default map specification for LDAP maps. The value should only contain LDAP specific settings such as <b>-h host -p port -d bindDN</b> . The settings will be used for all LDAP maps unless the individual map specification overrides a setting. This option should be set before any LDAP maps are defined.                                                                                                                                                                                                                                                                                                                |
| <b>LogLevel=<i>n</i></b>               | Set the log level to <i>n</i> . Defaults to 9.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Mxvalue</b>                         | Set the macro <i>x</i> to value. This is intended only for use from the command line. The <b>-M</b> flag is preferred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>MatchGECOS</b>                      | Allow fuzzy matching on the <b>GECOS</b> field. If this flag is set, and the usual user name lookups fail (that is, there is no alias with this name and a <b>getpwnam</b> fails), sequentially search the password file for a matching entry in the <b>GECOS</b> field. This also requires that <b>MATCHGECOS</b> be turned on during compilation. This option is not recommended.<br><b>Note:</b> Fuzzy matching is performed only on the NIS modules and on local users in the system.                                                                                                                                           |
| <b>MaxAliasRecursion=<i>N</i></b>      | <i>N</i> is the maximum depth of alias recursion. Default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>MaxDaemonChildren=<i>N</i></b>      | If set, <b>sendmail</b> will refuse connections when it has more than <i>N</i> children processing incoming mail or automatic queue runs. This does not limit the number of outgoing connections. If not set, there is no limit to the number of children; the system load averaging will controls this.                                                                                                                                                                                                                                                                                                                            |
|                                        | If the default <b>DeliveryMode</b> (background) is used, then <b>sendmail</b> may create an almost unlimited number of children (depending on the number of transactions and the relative execution times of mail reception and mail delivery). If the limit should be enforced, then a <b>DeliveryMode</b> other than background must be used. If not set, there is no limit to the number of children, that is, the system load average controls this.                                                                                                                                                                            |
| <b>MaxHeadersLength=<i>N</i></b>       | <i>N</i> is the maximum length of the sum of all headers. This can be used to prevent a denial of service attack. The default is no limit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>MaxHopCount=<i>N</i></b>            | The maximum hop count. Messages that have been processed more than <i>N</i> times are assumed to be in a loop and are rejected. Default is 25.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Item                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MaxMessageSize=N</b>           | Specify the maximum message size to be advertised in the ESMTP EHLO response. Messages larger than <i>N</i> will be rejected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>MaxMimeHeaderLength =N M </b>  | Sets the maximum length of certain MIME header field values to <i>N</i> characters. If <i>M</i> is specified, certain headers that take parameters will use <i>M</i> instead of <i>N</i> . If <i>M</i> is not specified, these headers will use one half of <i>N</i> . By default, these values are 0, which indicates no checks are done.                                                                                                                                                                                                                                                                                                                                                              |
| <b>MaxQueueRunSize=N</b>          | <i>N</i> is the maximum number of jobs that will be processed in a single queue run. If not set, there is no limit on the size. If you have very large queues or a very short queue run interval this could be unstable. However, because the first <i>N</i> jobs in queue directory order are run (rather than the <i>N</i> highest priority jobs) this should be set as high as possible to avoid losing jobs that happen to fall late in the queue directory.<br><b>Note:</b> This option also restricts the number of entries printed by <b>mailq</b> . That is, if the <b>MaxQueueRunSize</b> is set to a value <i>N</i> larger than zero, then only <i>N</i> entries are printed per queue group. |
| <b>MaxRecipientsPerMessage =N</b> | The maximum number of recipients that will be accepted per message in an SMTP transaction. If not set, there is no limit on the number of recipients per envelope.<br><b>Note:</b> Setting this too low can interfere with sending mail from MUAs that use SMTP for initial submission.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>MeToo</b>                      | Send to me too, even if I am in an alias expansion. This option is deprecated and will be removed from a future version.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>MinFreeBlocks=N</b>            | Sets at least <i>N</i> blocks free on the file system that holds the queue files before accepting e-mail via SMTP. If there is insufficient space, <b>sendmail</b> gives a 452 response to the <b>MAIL</b> command and invites the sender to try again later.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>MinQueueAge=age</b>            | Do not process any queued jobs that have been in the queue less than the indicated time interval. This promotes system responsiveness by processing the queue frequently without taxing the system by trying jobs too often. The default units are minutes.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>MustQuoteChars=s</b>           | Sets the list of characters that must be quoted if used in a full name that is in the phrase part of a <i>phrase &lt;address&gt;</i> syntax. The default is '..'. The characters '@,:;\\"[] are always added to this list.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>NoRecipientAction</b>          | The action to take when you receive a message that has no valid recipient headers, such as <b>To:</b> , <b>Cc:</b> , or <b>Bcc:</b> . It can be:<br><br><b>None</b> Passes the message on unmodified, which violates the protocol.<br><b>Add-To</b> Adds a <b>To:</b> header with any recipients it can find in the envelope (which might expose <b>Bcc:</b> recipients).<br><b>Add-To-Undisclosed</b><br>Adds a header <b>To: undisclosed-recipients:;</b> to make the header legal without disclosing anything.<br><b>Add-Bcc</b><br>Adds an empty <b>Bcc:</b> header.<br>                                                                                                                            |
| <b>OldStyleHeaders</b>            | Assume that the headers may be in old format with spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it will be assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names. Defaults to off.                                                                                                                                                                                                                                                                                                                              |
| <b>OperatorChars=charlist</b>     | The list of characters that are considered to be operators, that is, characters that delimit tokens. All operator characters are tokens by themselves; sequences of non-operator characters are also tokens. White space characters separate tokens but are not tokens themselves. For example, AAA.BBB has three tokens, but AAA BBB has two. If not set, <b>OperatorChars</b> defaults to ..@[]". In addition, the characters "()<>;" are always operators. Note that <b>OperatorChars</b> must be set in the configuration file before any rulesets.                                                                                                                                                 |
| <b>PidFile=filename</b>           | Sets the <i>filename</i> of the pid file. Default is PATHSENDMAILPID. The filename is macro-expanded before it is opened.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>PostmasterCopy=postmaster</b>  | If set, copies of error messages will be sent to the named <i>postmaster</i> . Only the header of the failed message is sent. Errors resulting from messages with a negative precedence will not be sent. Because most errors are user problems, this is not a good idea on large sites, and may contain privacy violations. The address is macro expanded at the time of delivery. Defaults to no <i>postmaster</i> copies.                                                                                                                                                                                                                                                                            |

| Item                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PrivacyOptions</b> = <i>opt,opt,...</i> | <p>Sets privacy options. These are a way of insisting on stricter adherence to the SMTP protocol. The options can be one of the following:</p> <ul style="list-style-type: none"> <li><b>public</b> Allow open access.</li> <li><b>needmailhelo</b> Insist on <b>HELO</b> or <b>EHLO</b> command before <b>MAIL</b>.</li> <li><b>needexpnhelo</b> Insist on <b>HELO</b> or <b>EHLO</b> command before <b>EXPN</b>.</li> <li><b>noexpn</b> Do not allow <b>EXPN</b>, implies noverb.</li> <li><b>needvrfyhelo</b> Insist on <b>HELO</b> or <b>EHLO</b> command before <b>VRFY</b>.</li> <li><b>novrfy</b> Do not allow <b>VRFY</b>.</li> <li><b>noetrn</b> Do not allow <b>ETRN</b>.</li> <li><b>noverb</b> Do not allow <b>VERB</b>.</li> <li><b>restrictmailq</b> Restrict <b>mailq</b> command. If <b>mailq</b> is restricted, only people in the same group as the queue directory can print the queue.</li> <li><b>restrictqrun</b> Restrict <b>-q</b> command line flag. If queue runs are restricted, only root and the owner of the queue directory can run the queue.</li> <li><b>noreceipts</b> Do not return success DSNs.</li> <li><b>nobodyreturn</b> Do not return the body of a message with DSNs.</li> <li><b>goaway</b> Do not allow <b>SMTP</b> status queries. Sets all flags except <b>noreceipts</b>, <b>restrictmailq</b>, <b>restrictqrun</b>, <b>noetrn</b>, and <b>nobodyreturn</b>.</li> <li><b>authwarnings</b> Put <b>X-Authentication-Warning:</b> headers in messages. Authentication Warnings add warnings about various conditions that may indicate attempts to spoof the mail system, such as using a nonstandard queue directory.</li> </ul> |

| Item                                      | Description                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ProcessTitlePrefix</b> = <i>string</i> | Prefix the process title shown on <b>ps</b> listings with <i>string</i> . The string will be macro processed.                                                                                                                                                                                                                                                                        |
| <b>QueueDirectory</b> = <i>dir</i>        | Use the named <i>dir</i> as the queue directory. To use multiple queues, supply a value ending with an asterisk. For example, entering <b>/var/spool/mqueue/q*</b> will use all of the directories or symbolic links to directories beginning with q in <b>/var/spool/mqueue</b> as queue directories. Do not change the queue directory structure while <b>sendmail</b> is running. |
| <b>QueueFactor</b> = <i>factor</i>        | Use <i>factor</i> as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit ( <b>QueueLA</b> option) to determine the maximum message priority that will be sent. Default is 600000.                                                      |
| <b>QueueLA</b> = <i>LA</i>                | When the system load average exceeds <i>LA</i> , just queue messages, do not try to send them. Defaults to 8 multiplied by the number of processors online on the system, if that can be determined.                                                                                                                                                                                 |

| Item                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QueueSortOrder=</b> <i>algorithm</i> | Sets the <i>algorithm</i> used for sorting the queue. Only the first character of the value is used. Legal values are: <ul style="list-style-type: none"> <li><b>host</b> Orders by the name of the first host name of the first recipient. Makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority messages that go to several hosts; it probably should not be used on slow network links.</li> <li><b>filename</b> Orders by the name of the queue file name. Saves the overhead of reading all of the queued items before starting the queue run.</li> <li><b>time</b> Orders by the submission time. Should not be used because it allows large, bulk mail to go out before smaller, personal mail. May be appropriate on certain hosts with very fast connections.</li> <li><b>priority</b> Orders by message priority. Is the default.</li> </ul>                                                                                                                                              |
| <b>QueueTimeout=</b> <i>time-out</i>    | Do not use. Use <b>Timeout.queuereturn</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>RandFile</b>                         | Name of file containing random data or the name of the socket if EGD is used. A required prefix <b>egd:</b> or <b>file:</b> specifies the type. STARTTLS requires this filename if the compile flag <b>HASURANDOM</b> is not set (see <b>/user/samples/tcpip/sendmail/README</b> ).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>ResolverOptions=</b> <i>options</i>  | Set resolver options. Values can be set using <b>+flag</b> and cleared using <b>-flag</b> . Available flags are: <ul style="list-style-type: none"> <li>• debug</li> <li>• aaonly</li> <li>• usevc</li> <li>• primary</li> <li>• igntc</li> <li>• recurse</li> <li>• defnames</li> <li>• stayopen</li> <li>• dnsrch</li> </ul> <p>The string <b>HasWildcardMX</b> (without a + or -) can be specified to turn off matching against MX records when doing name canonicalizations.</p> <p><b>Note:</b> In previous releases, this option indicated that the name server be responding in order to accept addresses. This has been replaced by checking to see if the DNS method is listed in the service switch entry for the hosts service.</p>                                                                                                                                                                                                                                                                                                                                    |
| <b>RrtImpliesDsn</b>                    | If this option is set, a <b>ReturnReceipt-To:</b> header causes the request of a DSN to be sent to the envelope sender as required by RFC1891, not to the address given in the header.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>RunAsUser=</b> <i>user</i>           | The user parameter may be a user name (looked up in <b>/etc/passwd</b> ) or a numeric user ID. Either form can have <b>:group</b> attached, <b>group</b> can be numeric or symbolic. If set to a non-zero/non-root value, <b>sendmail</b> will change to this user ID shortly after startup. This avoids a certain class of security problems. However, this means that all <b>.forward</b> and <b>:include:</b> files must be readable by the indicated user and all files to be written must be writable by <i>user</i> . Also, all file and program deliveries will be marked unsafe unless the option <b>DontBlameSendmail=NonRootAddrSafe</b> is set, in which case the delivery will be done as <i>user</i> . It is also incompatible with the <b>SafeFileEnvironment</b> option. It may not actually add much to security on an average system, and may in fact detract from security, because other file permissions must be loosened. However, it may be useful on firewalls and other places where users do not have accounts and the aliases file is well constrained. |
| <b>RecipientFactor=</b> <i>fact</i>     | The indicated <i>factor</i> is added to the priority for each recipient, thus lowering the priority of the job. This value penalizes jobs with large numbers of recipients. Defaults to 30000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>RefuseLA=</b> <i>LA</i>              | When the system load average exceeds <i>LA</i> , refuse incoming SMTP connections. Defaults to 12 multiplied by the number of processors online on the system, if that can be determined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>RetryFactor=</b> <i>fact</i>         | The <i>factor</i> is added to the priority every time a job is processed. Each time a job is processed, its priority will be decreased by the indicated value. In most environments this should be positive, because hosts that are down may be down for a long time. Default is 90000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Item                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SafeFileEnvironment</b> = <i>dir</i>     | If this option is set, <b>sendmail</b> will do a <b>chroot(2)</b> call into the indicated directory before doing any file writes. If the file name specified by the user begins with <i>dir</i> , that partial path name will be stripped off before writing. For example, if the <b>SafeFileEnvironment</b> variable is set to <i>/safe</i> then aliases of <i>/safe/logs/file</i> and <i>/logs/file</i> actually indicate the same file. Additionally, if this option is set, <b>sendmail</b> will refuse to deliver to symbolic links.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>SaveFromLine</b>                         | Save <b>From</b> lines at the front of headers. They are assumed to be redundant and are discarded.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SendMimeErrors</b>                       | If set, send error messages in MIME format (see RFC2045 and RFC1344 for details). If disabled, <b>sendmail</b> will not return the DSN keyword in response to an <b>EHLO</b> and will not do Delivery Status Notification processing as described in RFC1891.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ServerCertFile</b>                       | File containing the certificate of the server. This certificate is used when <b>sendmail</b> acts as server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>ServerKeyFile</b>                        | File containing the private key belonging to the server certificate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ServiceSwitchFile</b> = <i>filename</i>  | If your host operating system has a service switch abstraction, that service will be consulted and this option is ignored. Otherwise, this is the name of a file that provides the list of methods used to implement particular services. The syntax is a series of lines, each of which is a sequence of words. The first word is the service name, and following words are service types. The services that <b>sendmail</b> consults directly are <b>aliases</b> and <b>hosts</b> . Service types can be <b>dns</b> , <b>nis</b> , <b>nisplus</b> , or <b>files</b> . The appropriate support must be compiled in before the service can be referenced. If <b>ServiceSwitchFile</b> is not specified, it defaults to <i>/etc/mail/service.switch</i> . If that file does not exist, the default switch is<br><br><pre>aliases      files hosts       dns nis files</pre> <p>The default file is <i>/etc/mail/service.switch</i>.</p> |
| <b>SevenBitInput</b>                        | Strip input to seven bits for compatibility with old systems. This should not be necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SingleLineFromHeader</b>                 | If set, <b>From:</b> lines that have embedded newlines are unwrapped onto one line. This is to get around a bug in Lotus Notes® that apparently cannot understand legally wrapped RFC822 headers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SingleThreadDelivery</b>                 | If set, a client machine will never try to open two SMTP connections to a single server machine at the same time, even in different processes. That is, if another <b>sendmail</b> is already talking to some host, a new <b>sendmail</b> will not open another connection. Although this reduces the load on the other machine, it can cause mail to be delayed. For example, if one <b>sendmail</b> is delivering a huge message, other <b>sendmail</b> processes will not be able to send even small messages. Also, it requires another file descriptor (for the lock file) per connection, so you may have to reduce the <b>ConnectionCacheSize</b> option to avoid running out of per-process file descriptors. Requires the <b>HostStatusDirectory</b> option.                                                                                                                                                                  |
| <b>SntpGreetingMessage</b> = <i>message</i> | Specifies the <i>message</i> to print when the SMTP server starts up.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>StatusFile</b> = <i>file</i>             | Defaults to <b>\$j Sendmail \$v ready at \$b</b> .<br>Log summary statistics in the named <i>file</i> . If no file name is specified, <b>statistics</b> is used. If not set, no summary statistics will be saved. This file does not grow in size. It can be printed using the <b>mailstats(8)</b> program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>SuperSafe</b>                            | Always instantiate the queue file, even if you are going to attempt immediate delivery. <b>Sendmail</b> always instantiates the queue file before returning control to the client under any circumstances. This should always be set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Temp FileMode</b> = <i>mode</i>          | Specifies the file mode for queue files. It is interpreted in octal by default. Default is <b>0600</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Timeout.type</b> = <i>time-out</i>       | Sets <i>time-out</i> values. For more information, see "Read Timeouts" on page 281.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>TimeZoneSpec</b> = <i>tzinfo</i>         | Set the local time zone info to <i>tzinfo</i> . If this is not set, the TZ environment variable is cleared and the system default is used. If set but null, the user's TZ variable is used. If set and non-null, the TZ variable is set to this value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>TrustedUser</b> = <i>user</i>            | The user parameter can be a user name (looked up in <i>/etc/passwd</i> ) or a numeric user ID. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) will automatically be owned by this user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>TryNullMXList</b>                        | If this system is the best (that is, lowest preference) MX for a given host, its configuration rules should detect this situation and treat that condition specially by forwarding the mail to a UUCP feed, treating it as local, and so on. However, in some cases, such as in the case with Internet firewalls, you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes <b>sendmail</b> to try this. Unfortunately, errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is not recommended.                                                                                                                                                                                                                                                                            |

| Item                                            | Description                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>UnixFromLine</b> = <i>fromline</i>           | Defines the format used when <b>sendmail</b> must add a UNIX-style <b>From</b> line, such as a line beginning <b>From&lt;space&gt;user</b> ). Defaults to <b>From \$g \$d</b> . Do not change this unless your system uses a different mailbox format.                                                                                         |
| <b>UnsafeGroupWrites</b>                        | If set, <b>:include:</b> and <b>.forward</b> files that are group writable are considered unsafe, and they will not be able to reference programs or write directly to files. World writable <b>:include:</b> and <b>.forward</b> files are always unsafe.                                                                                     |
| <b>UserDatabaseSpec</b> = <i>udbspec</i>        | The user database specification.                                                                                                                                                                                                                                                                                                               |
| <b>Verbose</b>                                  | Run in Verbose mode. If this is set, <b>sendmail</b> adjusts options <b>HoldExpensive</b> and <b>DeliveryMode</b> so that all mail is delivered completely in a single job so that you can see the entire delivery process. The <b>Verbose</b> option should never be set in the configuration file; it is intended for command line use only. |
| <b>XscriptFileBufferSize</b> = <i>threshold</i> | Defines the <i>threshold</i> in bytes, before a memory-based queue transcript file becomes disk-based. The default is 4096 bytes.                                                                                                                                                                                                              |

All options can be specified on the command line using the **-O** or **-o** flag, but most will cause **sendmail** to relinquish its setuid permissions. The options that will not cause this are **SevenBitInput**, **EightBitMode**, **MinFreeBlocks**, **CheckpointInterval**, **DeliveryMode**, **ErrorMode**, **IgnoreDots**, **SendMimeErrors**, **LogLevel**, **OldStyleHeaders**, **PrivacyOptions**, **SuperSafe**, **Verbose**, **QueueSortOrder**, **MinQueueAge**, **DefaultCharSet**, **DialDelay**, **NoRecipientAction**, **ColonOkInAddr**, **MaxQueueRunSize**, **SingleLineFromHeader**, and **AllowBogusHELO**. Actually, **PrivacyOptions** given on the command line are added to those already specified in the **sendmail.cf** file and cannot be reset. Also, **M** (define macro) when defining the **r** or **s** macros is also considered safe.

## P - Precedence Definitions

Values for the "Precedence:" field may be defined using the **P** control line. The syntax of this field is:

**Pname=num**

When the name is found in a "Precedence:" field, the message class is set to num. Higher numbers mean higher precedence. Numbers less than zero have the special property that if an error occurs during processing, the body of the message will not be returned; this is expected to be used for "bulk" mail such as through mailing lists. The default precedence is zero. For example, the list of default precedences is:

- **Pfirst-class=0**
- **Pspecial-delivery=100**
- **Plist=-30**
- **Pbulk=-60**
- **Pjunk=-100**

## V - Configuration Version Level

To provide compatibility with old configuration files, the **V** line has been added to define basic semantics of the configuration file. This is *not* intended as long term support. These compatibility features may be removed in future releases.

**Note:** Configuration version *levels* are independent of configuration file version *numbers*. For example, version *number* 8.9 configuration files use version *level* 8 configurations.

"Old" configuration files are defined as version level one.

Version level two files make the following changes:

1. Host name canonicalization (**\$[ ... \$]**) appends a dot if the name is recognized. This gives the configuration file a way to determine if a match occurred. This initializes the host map with the **-a** flag. You can reset it to anything else by declaring the map explicitly.

2. Default host name extension is consistent throughout processing. Version level one configurations turned off domain extension during certain points in processing by adding the local domain name. Version level two configurations include a trailing dot to indicate that the name is already canonical.
3. Local names that are not aliases are passed through a new distinguished ruleset five. This can be used to append a local relay. This can be prevented by resolving the local name by using the @ symbol as a prefix (for example, @vikki). Something that resolves to a local mailer and a user name of vikki will be passed through ruleset five, but a user name of @vikki will have the @ prefix stripped, will not be passed through to ruleset five, but will otherwise be treated the same as the prior example. The exception is that this might be used to implement a policy where mail sent to vikki is handled by a central hub but mail sent to vikki@localhost is delivered directly.

Version level three files allow # initiated comments on all lines. Exceptions are backslash escaped # marks and the \$# syntax.

Version level four files are equivalent to level three files.

Version level five files change the default definition of \$w to be the first component of the hostname.

Version level six configuration files change many of the local processing options (i.e., aliasing and matching the address beginning for the ! character) to mailer flags. This allows fine grained control over the special local processing. Version level six files may also use long option names. The **ColonOkInAddr** option (which allows colons in the local part of the address) defaults to **on** in configuration files with lower version numbers. The configuration file requires additional "intelligence" to properly handle the RFC 822 group construct.

Version level seven configuration files use new option names to replace old macros.

| Option     | Old Macro           |
|------------|---------------------|
| \$e became | SmtpGreetingMessage |
| \$1 became | UnixFromLine        |
| \$o became | OperatorChars       |

Prior to version seven, the **F=q** flag (use the return value 250 instead of 252 for SMTP VRFY commands) was assumed.

Version level eight configuration files allow \$# on the left side of ruleset lines.

Version level nine configuration files allow parentheses in rulesets, which means they are not treated as comments and are removed.

The **V** line may have an optional */vendor* variable to indicate that the configuration file uses vendor specific modifications. You may use */Berkeley* to indicate that the file uses the Berkeley **sendmail** dialect.

## K - Key File Declaration

Special maps can be defined using the line:

```
Kmapname mapclass arguments
```

The mapname is the name by which this map is referenced in the rewrite rules. The mapclass is the name of a type of map; these are compiled in to **sendmail**. The arguments are interpreted depending on the class; typically, there would be a single argument naming the file containing the map.

Maps are referenced using the syntax:

```
$(map key $@ arguments $: default $)
```

where either or both of the arguments or default portion may be omitted. The \$@ arguments may appear more than once. The indicated key and arguments are passed to the appropriate mapping function. If it returns a value, it replaces the input. If it does not return a value and the default is specified, the default replaces the input. Otherwise, the input is unchanged.

During replacement of either a map value or default, the string "%n" (where n is a digit) is replaced by the corresponding argument. Argument zero is always the database key. For example, the rule:

```
R$- ! $+ $: $(uucp $1 $0 $2 $: %1 @ %0 . UUCP $)
```

looks up the UUCP name in a (user-defined) UUCP map. If not found, it turns it into ".UUCP" form. The database might contain records like:

```
devax %1@ %0.DEC.COM
research %1@%0.ATT.COM
```

**Note:** The default clauses never perform this mapping.

The built-in map with both name and class "host" is the host name canonicalization lookup. Thus, the syntax:

```
$(host hostname$)
```

is equivalent to:

```
$[hostname$]
```

There are many defined classes.

| Class    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dbm      | Database lookups using the <b>ndbm(3)</b> library. <b>Sendmail</b> must be compiled with NDBM defined.                                                                                                                                                                                                                                                                                                                                                    |
| btree    | Database lookups using the btree interface to the Berkeley DB library. <b>Sendmail</b> must be compiled with NEWDB defined.                                                                                                                                                                                                                                                                                                                               |
| hash     | Database lookups using the hash interface to the Berkeley DB library. <b>Sendmail</b> must be compiled with NEWDB defined.                                                                                                                                                                                                                                                                                                                                |
| nis      | NIS lookups. <b>Sendmail</b> must be compiled with NEWDB defined.                                                                                                                                                                                                                                                                                                                                                                                         |
| nisplus  | NIS+ lookups. <b>Sendmail</b> must be compiled with NISPLUS defined. The argument is the name of the table to use for lookups, and the -k and -v flags may be used to set the key and value columns respectively.                                                                                                                                                                                                                                         |
| ldap     | LDAP X500 directory lookups. <b>Sendmail</b> must be compiled with LDAPMAP defined. The map supports most of the standard arguments and command line arguments of the <b>ldapsearch</b> program. By default, if a single query matches multiple values, only the first value will be returned unless the -z (value separator) map flag is set. Also, the -1 map flag will treat a multiple value return as if there were no matches.                      |
| ldapx    | LDAP X500 directory lookups. <b>Sendmail</b> must be compiled with LDAPMAP defined. The map supports most of the standard arguments and command line arguments of the <b>ldapsearch</b> program.                                                                                                                                                                                                                                                          |
| text     | Text file lookups. The format of the text file is defined by the -k (key field number), -v (value field number), and -z (field delimiter) flags.                                                                                                                                                                                                                                                                                                          |
| stab     | Internal symbol table lookups. Used internally for aliasing.                                                                                                                                                                                                                                                                                                                                                                                              |
| implicit | Really should be called "alias." This is used to get the default lookups for alias files, and is the default if no class is specified for alias files.                                                                                                                                                                                                                                                                                                    |
| user     | Looks up users using <b>getpwnam(3)</b> . The -v flag can be used to specify the name of the field to return (although this is normally used only to check the existence of a user).                                                                                                                                                                                                                                                                      |
| host     | Canonicalizes host domain names. Given a host name, it calls the name server to find the canonical name for that host.                                                                                                                                                                                                                                                                                                                                    |
| bestmx   | Returns the best MX record for a host name given as the key. The current machine is always preferred. For example, if the current machine is one of the hosts listed as the lowest preference MX record, it will be guaranteed to be returned. This can be used to find out if this machine is the target for an MX record and mail can be accepted on that basis. If the -z flag is given, all MX names are returned (separated by the given delimiter). |

| Class                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sequence</b>                | <p>The arguments on the `K' line are a list of maps; the resulting map searches the argument maps in order until it finds a match for the indicated key. For example, if the key definition is:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                | <pre>Kmap1 ... Kmap1 ... Kseqmap sequence map1 map2</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                | <p>then a lookup against "seqmap" first does a lookup in map1. If that is found, it returns immediately. Otherwise, the same key is used for map2.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>syslog</b><br><b>switch</b> | <p>The key is logged via <code>syslogd(8)</code>. The lookup returns the empty string.<br/>Much like the "sequence" map except that the order of maps is determined by the service switch. The argument is the name of the service to be looked up; the values from the service switch are appended to the map name to create new map names. For example, consider the key definition:</p>                                                                                                                                                                                                                                                                        |

|                                | <p>will have quotes stripped, but the result is probably not what was intended. Fortunately, these cases are rare.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>regex</b>                   | <p>The map definition on the K line contains a regular expression. Any key input is compared to that expression using the POSIX regular expressions routines <code>regcomp()</code>, <code>regerr()</code>, and <code>regexec()</code>. Refer to the documentation for those routines for more information about regular expression matching. No rewriting of the key is done if the <code>-m</code> flag is used. Without it, the key is discarded, or if <code>-s</code> is used, it is substituted by the substring matches, delimited by the <code>\$1</code> or the string specified with the <code>-d</code> flag. The flags available for the map are:</p> |
|                                | <ul style="list-style-type: none"> <li><b>-n</b>      not</li> <li><b>-f</b>      case sensitive</li> <li><b>-b</b>      basic regular expressions (default is extended)</li> <li><b>-s</b>      substring match</li> <li><b>-d</b>      set the delimiter used for <code>-s</code></li> <li><b>-a</b>      append string to key</li> <li><b>-m</b>      match only, do not replace/discard value</li> </ul>                                                                                                                                                                                                                                                      |
|                                | <p>The <code>-s</code> flag can include an optional parameter which can be used to select the substrings in the result of the lookup. For example, <code>-s1,3,4</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>program</b>                 | <p>The arguments on the K line are the path name to a program and any initial parameters to be passed. When the map is called, the key is added to the initial parameters and the program is invoked as the default user/group ID. The first line of standard output is returned as the value of the lookup. This has many potential security problems and terrible performance. It should be used only when absolutely necessary.</p>                                                                                                                                                                                                                            |

| Class        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>macro</b> | <p>Set or clear a macro value. To set a macro, pass the value as the first argument in the map lookup. To clear a macro, do not pass an argument in the map lookup. The map always returns the empty string. Examples of typical usage includes:</p> <pre>Kstorage macro ... # set macro \${MyMacro} to the ruleset match R\$+      \$:\$(storage {MyMacro} \$0 \$1 \$) \$1 # set macro \${MyMacro} to an empty string R\$*      \$:\$(storage {MyMacro} \$0 \$) \$1 # set macro \${MyMacro} R\$-      \$:\$(storage {MyMacro} \$) \$1</pre> |
| <b>arith</b> | <p>Perform simple arithmetic operations. The operation is given as key, currently +, -, *, /, 1 (for less than), and = are supported. The two operands are given as arguments. The lookup returns the result of the computation (True or False) for comparisons, integer values otherwise. All options that are possible for maps are ignored. A simple example is:</p> <pre>Kcomp arith ... Scheck_etrrn R\$*      \$: \$(comp 1 \$0 \${load_avg} \$0 7 \$) \$1 RFALSE   \$# error ...</pre>                                                |

Most of these accept as arguments the same optional flags and a filename (or a mapname for NIS; the filename is the root of the database path, so that .db or some other extension appropriate for the database type will be added to get the actual database name). Known flags are:

| Flag             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-o</b>        | Indicates that this map is optional. That is, if it cannot be opened, no error is produced, and <b>sendmail</b> will behave as if the map existed but was empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>-N, -O</b>    | If neither <b>-N</b> or <b>-O</b> are specified, <b>sendmail</b> uses an adaptive algorithm to decide whether or not to look for null bytes on the end of keys. It starts by trying both; if it finds any key with a null byte, it never tries again without a null byte and vice versa. If <b>-N</b> is specified, it never tries without a null byte and if <b>-O</b> is specified, it never tries with a null byte. Setting one of these can speed matches but are never necessary. If both <b>-N</b> and <b>-O</b> are specified, <b>sendmail</b> will never try any matches at all. That is, everything will appear to fail.                                                                                       |
| <b>-ax</b>       | Append the string <i>x</i> on successful matches. For example, the default host map appends a dot on successful matches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>-Tx</b>       | Append the string <i>x</i> on temporary failures. For example, <i>x</i> would be appended if a DNS lookup returned server failed or an NIS lookup could not locate a server. See the <b>-t</b> flag for additional information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>-f</b>        | Do not fold upper to lower case before looking up the key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>-m</b>        | Match only (without replacing the value). If you only care about the existence of a key and not the value (as you might when searching the NIS map "hosts.byname" for example), this flag prevents the map from substituting the value. However, The <b>-a</b> argument is still appended on a match, and the default is still taken if the match fails.                                                                                                                                                                                                                                                                                                                                                                |
| <b>-keycol</b>   | The key column name (for NIS+) or number (for text lookups).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>-valcol</b>   | The value column name (for NIS+) or number (for text lookups).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>-zdelim</b>   | The column delimiter (for text lookups). It can be a single character or one of the special strings "\n" or "\t" to indicate newline or tab respectively. If omitted entirely, the column separator is any sequence of whitespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>-t</b>        | Normally, when a map attempts to do a lookup and the server fails (e.g., <b>sendmail</b> could not contact any name server — this is <i>not</i> the same as an entry not being found in the map), the message being processed is queued for future processing. The <b>-t</b> flag turns off this behavior, letting the temporary failure (server down) act as though it were a permanent failure (entry not found). It is particularly useful for DNS lookups, where another misconfigured name server can cause problems on your machine. Care must be taken to avoid "bouncing" mail that would be resolved correctly if another attempt were made. A common strategy is to forward such mail to another mail server. |
| <b>-D</b>        | Perform no lookup in deferred delivery mode. This flag is set by default for the <i>host</i> map.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>-Spacesub</b> | The character to use to replace space characters after a successful map lookup. This is especially useful for <b>regex</b> and <b>syslog</b> maps.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>-q</b>        | Do not dequote the key before lookup.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Flag      | Description                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-A</b> | When rebuilding an alias file, the <b>-A</b> flag causes duplicate entries in the text version to be merged. For example, the following two entries: |
|           | <pre>list: user1,user2 list: user3</pre>                                                                                                             |
|           | would be treated as if they were the following single entry:                                                                                         |
|           | <pre>list: user1,user2,user3</pre>                                                                                                                   |

The following additional flags are present in the LDAP map only:

| Flag                        | Description                                                                                                                                                  |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>-R</b>                   | Do not auto chase referrals. <b>Sendmail</b> must be compiled with <b>-DLAP_REFERRALS</b> to use this flag.                                                  |
| <b>-n</b>                   | Retrieve attribute names only.                                                                                                                               |
| <b>-rderef</b>              | Set the alias dereference option to one of the following: <b>never</b> , <b>always</b> , <b>search</b> , or <b>find</b> .                                    |
| <b>-sscope</b>              | Set search scope to one of the following: <b>base</b> , <b>one</b> (one level), or <b>sub</b> (subtree).                                                     |
| <b>-hhost</b>               | LDAP server host name.                                                                                                                                       |
| <b>-bbase</b>               | LDAP search base.                                                                                                                                            |
| <b>-pport</b>               | LDAP service port.                                                                                                                                           |
| <b>-ltimelimit</b>          | Time limit for LDAP queries.                                                                                                                                 |
| <b>-Zsizelimit</b>          | Size (number of matches) limit for LDAP queries.                                                                                                             |
| <b>-ddistinguished_name</b> | The distinguished name to use to log in to the LDAP server.                                                                                                  |
| <b>-Mmethod</b>             | The method to authenticate to the LDAP server. Should be one of the following: <b>LDAP_AUTH_NONE</b> , <b>LDAP_AUTH_SIMPLE</b> , OR <b>LDAP_AUTH_KRB4</b> .  |
| <b>-Ppasswordfile</b>       | The file containing the secret key for the <b>LDAP_AUTH_SIMPLE</b> authentication method or the name of the Kerberos ticket file for <b>LDAP_AUTH_KRB4</b> . |
| <b>-1</b>                   | Force LDAP searches to succeed only if a single match is found. If multiple values are found, the search will be treated as if no match was found.           |

The dbm map appends the strings **.pag** and **.dir** to the given filename; the two db-based maps append **.db**. For example, the map specification

```
Kuucp dbm -o -N /usr/lib/uucpmap
```

specifies an optional map named "uucp" of class "dbm"; it always has null bytes at the end of every string, and the data is located in **/usr/lib/uucpmap.{dir,pag}**.

## Commands and Operands

| Command and Operand                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CXWord1 Word2...</b>                          | Defines the class of words that can be used to match the left-hand side of rewrite rules. Class specifiers (X) may be any of the uppercase letters from the ASCII character set. Lowercase letters and special characters are reserved for system use.                                                                                                                                                                                                                                                               |
| <b>DXValue</b>                                   | Defines a macro (X) and its associated <i>Value</i> . Macro specifiers may be any of the uppercase letters from the ASCII character set. Lowercase letters and special characters are reserved for system use.                                                                                                                                                                                                                                                                                                       |
| <b>FXFileName [Format]</b>                       | Reads the elements of the class (X) from the <i>FileName</i> variable, using an optional <b>scanf</b> format specifier. The format specifier contains only one conversion specification. One class number is read for each line in the <i>FileName</i> variable.                                                                                                                                                                                                                                                     |
| <b>H[?MFlags?]HeaderName:<br/>HeaderTemplate</b> | Defines the header format the <b>sendmail</b> command inserts into a message. Continuation lines are a part of the definition. The <i>HeaderTemplate</i> is macro-expanded before insertion into the message. If the <i>MFlags</i> are specified and at least one of the specified flags is included in the mailer definition, this header is automatically written to the output message. If the header appears in the input message, it is written to the output message regardless of the <i>MFlags</i> variable. |
| <b>MName, [Field=Value]</b>                      | Defines a Mail program where the <i>Name</i> variable is the name of the Mail program and <i>Field=Value</i> pair defines the attributes of the mailer.                                                                                                                                                                                                                                                                                                                                                              |

| Command and Operand                     | Description                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Ox[Value]                               | Sets the option to the value of <i>x</i> . If the option is a valued option, you must also specify the <i>Value</i> variable. Options may also be selected from the command line.<br><b>Note:</b> For valid values, see "O — Set Option" on page 292.                                                                                                                          |
| PName=Number                            | Defines values for the Precedence: header field. When the <i>Name</i> variables found in a message's Precedence: field, the message's precedence is set to the <i>Number</i> variable. Higher numbers indicate higher precedences. Negative numbers indicate that error messages are not returned. The default <i>Number</i> is 0.                                             |
| RLeftHandSide RightHandSide<br>Comments | Defines a rewrite rule. One or more tab characters separate the three fields of this command. If space characters are used as field separators, option J must be set. The J option allows spaces as well as tabs to separate the left- and right-hand sides of rewrite rules. The J option allows rewrite rules to be modified using an editor that replaces tabs with spaces. |
| Sx                                      | Sets the rule set currently defined to the specified number( <i>x</i> ). If a rule set definition is started more than once, the new definition overwrites the old.                                                                                                                                                                                                            |
| TUser1 User2 ...                        | Defines user IDs for the system administrators. These IDs have permission to override the sender address using the -f flag. More than one ID can be specified per line.                                                                                                                                                                                                        |

## Files

| Item                  | Description                                          |
|-----------------------|------------------------------------------------------|
| /etc/mail/sendmail.cf | Specifies the path of the sendmail.cf file.          |

sendmail command

## setinfo File

### Purpose

Describes the format of a set characteristics file.

### Description

The **setinfo** file is an ASCII file that describes the characteristics of the set along with information that helps control the flow of installation. It is created by the software set developer and is included in the Set Installation Package (SIP). A SIP is a special purpose package that controls the installation and removal of a set of packages.

Each entry in the **setinfo** file is a line that consists of predefined fields. Each entry corresponds to a package belonging to the set and must contain the following <tab>-separated fields:

#### 1. Package Abbr

This field contains the abbreviated name of the package. The abbreviation must be a short string (no more than nine characters long) and must conform to the file naming rules. All characters in the abbreviation must be alphanumeric and the first character cannot be numeric. **install**, **new**, and **all** are reserved.

This abbreviated name must be the same as the one used in **pkginfo**.

#### 2. Parts

This field specifies the number of parts this package consists of.

#### 3. Default

This field contains the character 'y' indicating that the package is to be installed as a default. Conversely, an 'n' indicates that the package will not be installed.

#### 4. Category

The category under which the package belongs. Release 4 defines four categories: "application," "graphics," "system" and "utilities." All packages must be assigned to one of these categories. If you choose, you can also assign a package to a category you defined. Categories are case-insensitive and may contain only alphanumerics. Each category is limited to 16 characters.

#### 5. Package Full-Name

Text that specifies the package name (maximum length of 256 ASCII characters). This field must be the same as **NAME** in the **pkginfo** file.

The order of the packages listed in the **setinfo** file must reflect any package dependencies (if any) and must represent the order in which packages occur on the media (in the case of datastream). Any package for which there exists a dependency must be listed prior to the package(s) that depends on it.

## Examples

Shown below is a **setinfo** file for set **admin**:

```
#ident "@(#)set:cnn/set/admin/setinfo 1.2"
#ident "$Header: $"

Format for the setinfo file. Field separator is: <tab>
pkg parts default category pkg full-name
abbr y/n

oam 4 y application OA&M
bkrs 1 y system Extended Backup and Restore
face 1 y application FACE
```

## setup.csh File

### Purpose

Sets the C-shell environment variables needed to build an InfoCrafter database.

### Description

The **setup.csh** file defines C-shell environment variables necessary to build an InfoCrafter database from the command line. The **setup.csh** file contains the definition of the **TOOLSDIR** and **TOPLEVEL\_BUILDDIR** variables; if there are relative path names of source files in your input list, it also sets the **TOPLEVEL\_SOURCEDIR** variable. The **TOOLSDIR** variable is added to your path environment variable so you can use the **icft** command without specifying the full path name.

The default value for the **TOOLSDIR** environment variable is **/usr/lpp/icraft/bin**. The **TOPLEVEL\_SOURCEDIR** and **TOPLEVEL\_BUILDDIR** variables have no default values.

You must copy the **setup.csh** file from **/usr/lpp/icraft/bin** to another location (such as your home directory) and edit it to define the variables. Then, use the **source setup.csh** command to assign the new definitions to the variables.

## Examples

A sample **setup.csh** file appears as follows:

```
setenv TOPLEVEL_SOURCEDIR $HOME/desktop
setenv TOOLSDIR /usr/lpp/icraft/bin
setenv TOPLEVEL_BUILDDIR $TOOLSDIR/master
```

To set the C-shell environment variables, enter the following:

```
source setup.csh
```

The following message is displayed:

```
setup.csh: assigning environment variables
for InfoCrafter. . .
```

## Files

| Item                          | Description                                                |

"setup.sh File"

## setup.sh File

### Purpose

Defines the Bourne or Korn shell environment variables needed to build an InfoCrafter database.

### Description

The **setup.sh** file defines Bourne or Korn shell environment variables necessary to build an InfoCrafter database from the command line using the **icft** command. The **setup.sh** file sets the **TOOLS\_DIR** and **TOPLEVEL\_BUILDDIR** variables. If there are relative path names of source files in your input list, it also sets the **TOPLEVEL\_SOURCEDIR** variable. The **TOOLS\_DIR** variable is added to your path environment variable so you can enter the **icft** command without specifying the full path name.

Default value for the **TOOLS\_DIR** environment path variable is **/usr/lpp/icraft/bin**.

**TOPLEVEL\_SOURCEDIR** and **TOPLEVEL\_BUILDDIR** have no default values.

You must copy the **setup.sh** file from **/usr/lpp/icraft/bin** to another location (such as your home directory) and edit it to define the variables. Then, use the **. setup.sh** command to set the variables to the defined values.

### Examples

A sample **setup.sh** file appears as follows:

```
TOPLEVEL_SOURCEDIR = $HOME/desktop
TOOLS_DIR = /usr/lpp/icraft/bin
TOPLEVEL_BUILDDIR = $TOOLS_DIR/master
```

To set Bourne or Korn shell environment variables, enter the following:

```
. setup.sh
```

The following message is given:

```
setup.sh: assigning environment variables for InfoCrafter
```

## slp.conf File

### Purpose

File used by SLP APIs.

### Description

To use the */etc/slpx.conf* file, ensure that all parameters for an entry are contained on one line in the configuration file. Comments can be included in the file beginning with a pound sign (#) in column 1.

The format is:

```
<keyword> = <value>
```

or

```
<keyword> = <value1>,<value2>,..., <valueN>
```

If there are more than 1 value to be configured, use a comma (,) as a separator.

If there are multiple lines configured against the same <keyword>, the first valid configured line is read, and the rest are ignored.

### Parameters

- 

#### **net.slpx.maxResults**

A 32-bit integer that gives the maximum number of results to accumulate and return for a synchronous request before the timeout. Positive integers and -1 are legal values. A value of -1 indicates that all results should be returned. The default value is -1. For example:

```
net.slpx.maxResults = 35
```

- 

#### **net.slpx.useScopes**

A value-list of strings that indicate the only scopes a UA or SA is allowed to use when making requests or registering. Otherwise, indicates the scopes a DA must support. The default scope "DEFAULT" is used if no other information is available. For example:

```
net.slpx.useScopes = david,bob
```

- 

#### **net.slpx.DAAddress**

A value-list of IP addresses or DNS resolvable host names giving the SLPv2 DAs to use for statically configured UAs and SAs. The default is none. For example:

```
net.slpx.DAAddress = 9.3.149.20, blahblah.ibm.com
```

- 

#### **net.slpx.isBroadcastOnly**

A boolean indicating whether broadcast should be used instead of multicast. The default is false (that is, multicast is used). For example:

```
net.slpx.isBroadcastOnly = false
```

- net.slp.multicastTTL**  
A positive integer less than or equal to 255, giving the multicast TTL. The default is 255 (in seconds). For example:

```
net.slp.multicastTTL = 255
```
- net.slp.DAActiveDiscoveryInterval**  
# A 16-bit positive integer giving the number of seconds between DA active discovery queries. If this parameter is set to 0, the active discovery is turned off. This property corresponds to the protocol specification parameter **CONFIG\_DA\_FIND**. The default is 900 (in seconds). For example:

```
net.slp.DAActiveDiscoveryInterval = 1200
```
- net.slp.multicastMaximumWait**  
A 32-bit integer giving the maximum amount of time to perform multicast, in milliseconds. This property corresponds to the **CONFIG\_MC\_MAX** parameter in the protocol specification. The default is 15000 (in ms). For example:

```
net.slp.multicastMaximumWait = 10000
```
- net.slp.multicastTimeouts**  
A value-list of 32-bit integers used as timeouts, in milliseconds, to implement the multicast convergence algorithm. Each value specifies the time to wait before sending the next request. This property corresponds to the **CONFIG\_MC\_RETRY** parameter in the protocol specification. The default is 3000,3000,3000,3000,3000 (in ms). There is no limitation on the maximum number entries to be specified. However the total sum of the entries cannot be greater than **CONFIG\_MC\_RETRY** (15000 in ms). For example:

```
net.slp.multicastTimeouts = 2000, 3000, 4000
```
- net.slp.DADiscoveryTimeouts**  
A value-list of 32-bit integers used as timeouts, in milliseconds, to implement the multicast convergence algorithm during active DA discovery. Each value specifies the time to wait before sending the next request. This property corresponds to the protocol specification parameter **CONFIG\_RETRY**. The default is 2000,2000,2000,2000,3000,4000 (in ms). There is no limitation on the maximum number entries to be specified. However the total sum of the entries cannot be greater than **CONFIG\_RETRY** (15000 in ms). For example:

```
net.slp.DADiscoveryTimeouts = 2000, 3000, 4000
```
- net.slp.datagramTimeouts**  
A value-list of 32-bit integers used as timeouts, in milliseconds, to implement unicast datagram transmission to DAs. The *n*th value gives the time to block waiting for a reply on the *n*th try to contact the DA. The sum of these values is the protocol specification property **CONFIG\_RETRY\_MAX**. The default is 2000, 2000, 2000, 2000, 3000, 4000 (in ms). There is no limitation on the maximum number of entries to be specified. However, the total sum of the entries cannot be greater than **CONFIG\_RETRY\_MAX** (15000 in ms). For example:

```
net.slp.datagramTimeouts = 2000, 3000, 4000
```
- net.slp.loglevel**  
By default, the SLP daemon logs messages up to level 3 to the **syslog** file. You can set the variable **slp.net.loglevel** to 6 or 7 for additional logging. Supported values follows:

- 3 Logs error messages. This is default level.
- 6 Logs informational messages.
- 7 Logs debug level messages.

## **smi.my File**

### **Purpose**

Provides sample SMI input to the **mosy** command.

### **Description**

The **/usr/samples/snmpd/smi.my** file is a sample input file to the **mosy** command, which creates an objects definition file for use by the **snmpinfo** command. The **mosy** compiler requires its input file to contain the ASN.1 definitions described in the Structure and Identification of Management Information (SMI) RFC 1155 and the Management Information Base (MIB) RFC 1213. The **smi.my** file contains the syntax descriptions from the SMI RFC 1155.

The **smi.my** file begins with a definition of the SNMP subtree of the MIB as assigned by the Internet Activities Board (IAB). It then contains the syntax definitions defined in RFC 1155.

Comments are specified by - - (two dashes). A comment can begin at any location and extends to the end of the line.

The **smi.my** file was created by extracting the definitions from Chapter 6 of RFC 1155. This file is shipped as **/usr/samples/snmpd/smi.my**. The file is part of Simple Network Management Protocol Agent Applications in Network Support Facilities.

### **Files**

| Item                               | Description                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>/usr/samples/snmpd/mibII.my</b> | Contains the ASN.1 definitions for the MIB II variables defined in RFC 1213.                                                                                                      |
| <b>/etc/mib.defs</b>               | Defines the Management Information Base (MIB) variables the <b>snmpd</b> agent should recognize and handle. This file is in the format that the <b>snmpinfo</b> command requires. |

## **smitacl.group File**

### **Purpose**

Contains the group access control list (ACL) definitions for the System Management Interface Tool (SMIT).

## Description

The **/etc/security/smitacl.group** file contains the group ACL definitions for SMIT. This is an ASCII file that contains a stanza for each system group. Each stanza is identified by a group name followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute pair ends with a newline character as does each stanza.

The file supports a default stanza. If an attribute is not defined, either the default stanza or the default value for the attribute is used.

A stanza contains the following attribute:

| Item           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>screens</b> | Describes the list of SMIT screens for this group. (It is of the type SEC_LIST.) Examples include:<br><pre>screens = *          # Permit all screen access.<br/>screens = !*         # Deny all screen access.<br/>screens =           # Allows no specific screens<br/>                   # (screens can be added on a per user basis)<br/>screens = user,group,!tcpip # Allow user &amp; group<br/>                           # screens, but not<br/>                           # tcpip screen</pre> |

For a typical stanza, see the "Examples" section. This file may be viewed with the **lssec** command and modified with the **chsec** command.

The screen names specified in the screens attribute are SMIT fastpath values. Many SMIT fastpath values can be found in the commands documentation. The **smit** command may also be used to determine the fastpath of the current screen. Please see the **smit** command for more information.

## Security

Access Control: This file grants read and write access to the root user, and read access to members of the security group.

## Examples

1. A typical stanza looks like the following example for the group called **group**:

```
group:
 screens = *
```

2. To allow the **mksysb** screen only for a member of a group called **bkupgrp**, remove the default access to all screens and specify only the **mksysb** screen for the **bkupgrp** group by typing:

```
default:
 screens =
bkupgrp:
 screens = mksysb
```

**Note:** Changing the default stanza will remove the default access to all screens for members of other groups.

3. To allow members of the **security** group to view the screens for user and group administration, add the following stanza:

```
security:
 screens = top_menu,security,users,groups
```

Additional screens may be granted to individual users by adding stanzas for each user to the **smitacl.user** file.

## Files

| Item                        | Description                               |
|-----------------------------|-------------------------------------------|
| /etc/security/roles         | Contains the list of valid roles.         |
| /etc/security/user.roles    | Contains the list of roles for each user. |
| /etc/security/smitacl.group | Contains the group ACL definitions.       |
| /etc/security/smitacl.user  | Contains the user ACL definitions.        |

### Related information:

chsec command  
lssec command  
getusraclattr

## smitacl.user File

### Purpose

Contains the user access control list (ACL) definitions for the System Management Interface Tool (SMIT).

### Description

The **/etc/security/smitacl.user** file contains the ACL definitions for SMIT. This is an ASCII file that contains a stanza for each system user. Each stanza is identified by a user name followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute pair ends with a newline character as does each stanza.

The file supports a default stanza. If an attribute is not defined, either the default stanza or the default value for the attribute is used.

A stanza contains the following attributes:

| Attribute       | Description                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>screens</b>  | Describes the list of SMIT screens for the user. (It is of the type <b>SEC_LIST</b> .) Examples include:<br><br>screens = * # Permit all screen access.<br>screens = !* # Deny all screen access.<br>screens = # Allows no specific screens<br># (screens can be added on a per user basis)<br>screens = user,group,!tcpip # Allow user & group<br># screens, but not<br># tcpip screen                                     |
| <b>funcmode</b> | Describes if the role database and/or SMIT ACL database should be used to determine accessibility. It also describes how to combine the <b>screens</b> data from the two databases. (It is of the type <b>SEC_CHAR</b> .) Examples include:<br><br>funcmode = roles+acl # Use both roles and SMIT ACL # databases.<br>funcmode = roles # Use only the roles database.<br>funcmode = acl # Use only the SMIT ACL # database. |

The defined values for **funcmode** are:

- roles** Only the screen values from the roles database are used.
- acl** Only the screen values from the SMIT ACL database are used.

#### **roles+acl**

The screen values from both the roles and the SMIT ACL databases are used.

For a typical stanza, see the "Examples" section . This file may viewed with the **lssec** command and modified with the **chsec** command.

The screen names specified in the screens attribute are SMIT fastpath values. Many SMIT fastpath values can be found in the commands documentation. The **smit** command may also be used to determine the fastpath of the current screen. Please see the **smit** command for more information.

## Security

Access Control: This file grants read and write access to the root user, and read access to members of the security group.

## Examples

1. To allow **pwduser** to access the groups which are accessible via the **users** and **passwd** SMIT fastpaths, type the following:

```
pwduser:
 funcmode = roles+acl
 screens = users,passwd
```

2. To allow the **mksysb** screen only for user **bkupuser**, add the following stanza:

```
bkupuser:
 screens = mksysb
```

## Files

| Item                        | Description                               |
|-----------------------------|-------------------------------------------|
| /etc/security/roles         | Contains the list of valid roles.         |
| /etc/security/user.roles    | Contains the list of roles for each user. |
| /etc/security/smitacl.group | Contains the group ACL definitions.       |
| /etc/security/smitacl.user  | Contains the user ACL definitions.        |

## snmpd.conf File

### Purpose

Defines a sample configuration file for the **snmpdv1** agent.

### Description

The **snmpd.conf** file provides the configuration information for the **snmpdv1** agent. This file can be changed while the **snmpdv1** agent is running. If the **refresh** or **kill -1** command is issued, the **snmpdv1** agent will reread this configuration file. The **snmpdv1** agent must be under System Resource Control (SRC) for the **refresh** command to force the reread. This file is part of Simple Network Management Protocol Agent Applications in Network Support Facilities.

This configuration file contains:

- Entries for Community names
- Access privileges and view definitions for incoming Simple Network Management Protocol (SNMP) request packets
- Entries for host destinations for trap notification
- Entries for log file characteristics
- Entries for snmpd-specific parameters

- Entries for SNMP Multiplexing Protocol (SMUX) association configurations
- Entries for the **sysLocation** and **sysContact** variables.

The **snmpd.conf** file must be owned by the root user. If the **snmpd.conf** file is not owned by root, or if the **snmpdv1** daemon cannot open the configuration file, the **snmpdv1** daemon issues a **FATAL** message to the logfile if logging is enabled and **snmpdv1** terminates.

Certain rules apply for specifying particular parameters in entries in the **snmpd.conf** configuration file. Some entries require the specification of object identifiers or object names or both. The following rules apply:

- An object identifier is specified in dotted numeric notation and must consist of at least three elements. The maximum number of elements in the object identifier is 50. Elements are separated by a . (dot). The first element must be a single digit in the range of 0 to 2. The second element must be an integer in the range of 1 to 40. The third and subsequent elements must be integers in the range of 1 to the size of an unsigned integer.
- An object name consists of a textual name with an optional numeric instance. The object name must be known to the **snmpdv1** agent. Object names typically are names of nodes in the Management Information Base (MIB) tree. If the root of the MIB tree, iso, is specified as an object name, the numeric instance is absolutely required. A . (dot) separates the textual name from the numeric instance.

## Community Entry

The community entry specifies the communities, associated access privileges and MIB views the **snmpdv1** agent allows. See example 1 for a sample entry. A community entry must be in the following format:

`community CommunityName IPAddress NetMask Permissions ViewName`

The following definitions apply to the variables in a community entry:

| Item                 | Description                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CommunityName</i> | The community name.                                                                                                                                                                                                                     |
| <i>IPAddress</i>     | The host name, IPv4 address in dotted-decimal format, or IPv6 address for the specified community name.                                                                                                                                 |
| <i>NetMask</i>       | A network mask in dotted-decimal format for the specified IPv4 address, or a prefix length in the range of 0 through 128 for the specified IPv6 address.                                                                                |
| <i>Permissions</i>   | Specifies one of: <ul style="list-style-type: none"> <li>readOnly</li> <li>writeOnly</li> <li>readWrite</li> <li>none.</li> </ul> The <i>Permissions</i> string is case-insensitive.                                                    |
| <i>ViewName</i>      | A unique object identifier in dotted numeric notation that is associated with a portion of the MIB tree to which the specified community name allows access. The <i>ViewName</i> value is the same as that specified in the view entry. |

The minimum specification required for a community entry is:

`community CommunityName`

The default values for this minimum community entry are:

| Item               | Description |
|--------------------|-------------|
| <i>IPAddress</i>   | 0.0.0.0     |
| <i>NetMask</i>     | 0.0.0.0     |
| <i>Permissions</i> | readOnly    |
| <i>View</i>        | iso.3       |

Fields to the right of the minimum entry are optional, with the limitation that no fields to the left of a specified field are omitted. Any information to the right of the *ViewName* variable is ignored. If an *IPAddress* of 0.0.0.0 is specified, the default *NetMask* is 0.0.0.0. If an *IPAddress* other than 0.0.0.0 is specified, the default *NetMask* is 255.255.255.255.

The *Permissions* default is readOnly. If the *ViewName* is not specified, the view for this community defaults to ISO, the entire MIB tree. For example:

```
community public 192.100.154.1
```

is a valid entry with the default values:

| Item               | Description     |
|--------------------|-----------------|
| <i>NetMask</i>     | 255.255.255.255 |
| <i>Permissions</i> | readOnly        |
| <i>View</i>        | iso.3           |

The following entry is not valid because the required *NetMask* variable to the left of the *Permissions* variable is not specified:

```
community public 192.100.154.1
readWrite
```

In this case, the value in the *Permissions* variable is accepted as the *NetMask* value. Since the value in the *Permissions* variable is not in the format required for the *NetMask* variable, an error will occur. The **snmpdv1** agent logs an EXCEPTIONS message if logging is enabled. In the case of an invalid community entry, the **snmpdv1** agent ignores the entry.

## View Entry

The view entry specifies the MIB subtrees to which a particular community has access. See example 3 for a sample entry. A view entry must be in the following format:

```
view ViewName MibSubtree...
```

The following definitions apply to the variables in the *view* entry:

| Item              | Description                                                                                                                                                                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ViewName</i>   | Specifies a unique object identifier in dotted-numeric notation that is associated with a portion of the MIB tree. This <i>ViewName</i> value is the same as that in the community entry and must be formatted as described there.                      |
| <i>MibSubtree</i> | A list of MIB subtrees, or MIB groups, specified as either an object name or an object identifier, that is associated with the <i>ViewName</i> variable. If the <i>MIBSubtree</i> list is not specified, the view defaults to iso, the entire MIB tree. |

Together, the view entry and its associated community entry define an access privilege or MIB view allowed by the **snmpdv1** agent.

In the case of an invalid view entry, the **snmpdv1** agent logs an EXCEPTIONS message, if logging is enabled, and ignores the view entry.

If a *ViewName* is specified in the community entry, but there is no view entry to describe that *ViewName*, the **snmpdv1** agent logs an EXCEPTIONS message stating that there is no such view for the community. The **snmpdv1** agent will allow no access for that community and view association.

## Trap Entry

The trap entry specifies the hosts the **snmpdv1** agent notifies in the event a trap is generated. See Example 2 for a sample entry. A trap entry must be in the following format:

```
trap CommunityName IPAddress ViewName TrapMask
```

In this format, the variable definitions are as follows:

| Item                 | Description                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>CommunityName</i> | The community name to be encoded in the SNMP trap packet.                                                                                                                                                                                                                                                                                                                                                       |
| <i>IPAddress</i>     | The host name, or IPv4 address in dotted-decimal format, or IPv6 address for the specified community name.                                                                                                                                                                                                                                                                                                      |
| <i>ViewName</i>      | The <b>snmpdv1</b> agent only checks the <i>ViewName</i> to verify that the format is valid and that there are no duplicate <i>ViewName</i> variables specified.                                                                                                                                                                                                                                                |
| <i>TrapMask</i>      | The trap mask in hexadecimal format. The bits from left to right stand for <i>coldStart</i> trap, <i>warmStart</i> trap, <i>linkDown</i> trap, <i>linkUp</i> trap, <i>authenticationFailure</i> trap, <i>egpNeighborLoss</i> trap, and <i>enterpriseSpecific</i> trap. The rightmost bit does not have any meaning. A value of 1 will enable the corresponding trap to be sent. Otherwise, the trap is blocked. |

For example:

| hexadecimal | bits      | meaning                                               |
|-------------|-----------|-------------------------------------------------------|
| fe          | 1111 1110 | block no traps                                        |
| 7e          | 0111 1110 | block <i>coldStart</i> trap                           |
| be          | 1011 1110 | block <i>warmStart</i> trap                           |
| 3e          | 0011 1110 | block <i>coldStart</i> trap and <i>warmStart</i> trap |

The minimum specification required for a trap entry is:

```
trap CommunityName IPAddress
```

The default value of *TrapMask* for this minimum trap entry is fe. There is no trap blocked for this case.

Fields to the right of the minimum entry are optional, with the limitation that no fields to the left of a specified field are omitted. There should be no information to the right of the *TrapMask* variable.

In the case of an invalid trap entry, the **snmpdv1** agent places an EXCEPTIONS message in the log file if logging is enabled and ignores the trap entry.

It is assumed that all hosts listed in the trap entries are listening on well-known UDP port 162 for SNMP traps. Because community views for traps are not supported, the **snmpdv1** agent will send trap messages for all traps generated as indicated by the *TrapMask* variable to the hosts listed in the trap entries. If no trap entry appears in the **snmpd.conf** file, the **snmpdv1** agent will not send out trap messages upon the generation of a trap.

## Logging Entry

The logging entry specifies the characteristics for the **snmpdv1** agent logging activities if logging is not directed from the **snmpd** command with the -f option. See example 4 for a sample entry. A logging entry must be in the following format:

```
logging FileName Enablement
logging size=Limit level=DebugLevel
```

The following definitions apply to the fields in the logging entries:

| <b>Item</b>       | <b>Description</b>                                                                                                         |
|-------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>FileName</i>   | Specifies the complete path and file name of the log file.                                                                 |
| <i>Limit</i>      | Specifies the maximum size in bytes of the specified log file. If the limit is specified as 0, the file size is unlimited. |
| <i>DebugLevel</i> | Specifies the level of logging, which can be one of the following:                                                         |
|                   | 0      All NOTICES, EXCEPTIONS, and FATAL messages                                                                         |
|                   | 1      Level 0 plus DEBUG messages                                                                                         |
|                   | 2      Level 1 plus a hexadecimal dump of incoming and outgoing packets                                                    |
|                   | 3      Level 2 plus an English version of the request and response packets                                                 |
| <i>Enablement</i> | Specifies whether logging is active. The following options are available:                                                  |
|                   | <b>enabled</b> Turns logging on.                                                                                           |
|                   | <b>disabled</b> Turns logging off.                                                                                         |

There is no default log file. The *Enablement* default is disabled. The log file size *Limit* default is 0, which means unlimited. The *DebugLevel* default is 0 if the **snmpd** command is invoked without the **-d** option. If the **-d** option is specified, the default *DebugLevel* is the value specified by the **-d** option on the **snmpd** command line.

The **size=** and **level=** entries are absolutely required if a size or debug level are specified. There can be no spaces around the **=** (equal sign).

There are no restrictions regarding the order in which the variables are entered in the logging entries. A logging entry can contain single or multiple variables.

If the value for the **size=** field or *DebugLevel* variable cannot be converted into an integer, the default size and debug level are used. Because the **snmpd** command sets the log file configuration parameters immediately upon reading them, the parameters in the logging entry are not necessarily ignored if the **snmpd** command determines there is an invalid field in that entry. For example, in the following invalid logging entry:

```
logging size=100000 garbagestuff enabled
```

The **snmpd** command will set the size parameter, but will discard all information from the field value of **garbagestuff** to the end of the line. In addition, an EXCEPTIONS message will be logged if logging is enabled.

### **snmpd Entry**

The **snmpd** entry specifies configuration parameters for the **snmpdv1** agent. See example 5 for a sample entry. An **snmpd** entry must be in the following format:

```
snmpd Variable=Value
```

The **=** (equal sign) is absolutely required; there can be no spaces around it.

The following definitions apply to the **snmpd** entry:

| Item            | Description                                                                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Variable</i> | Specifies the specific configuration parameter. <i>Variable</i> can be one of the following values: <ul style="list-style-type: none"> <li>• <b>maxpacket</b></li> <li>• <b>querytimeout</b>.</li> </ul> |
| <i>Value</i>    | Specifies the value of the specific variable.                                                                                                                                                            |

The configurable variables and allowable values are:

| Item                | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maxpacket</b>    | The maximum packet size, in bytes, that the <b>snmpdv1</b> agent will transmit. The minimum to which this variable can be set is 300 bytes. The maximum value to which this variable can be set is 56KB. If there is no <b>snmpd</b> entry for <b>maxpacket</b> , the system socket default levels will be used.                                                                                            |
| <b>querytimeout</b> | The time interval in seconds at which the <b>snmpdv1</b> agent will query the interfaces to check for interface status changes. The minimum value to which <b>querytimeout</b> can be set is 30 seconds. If 0 is specified, the <b>snmpdv1</b> agent will not query the interfaces for status changes. If there is no <b>snmpd</b> entry for <b>querytimeout</b> , the default value of 60 seconds is used. |

The = (equal sign) is absolutely required; there can be no white space around it. There are no restrictions on the order in which the variables are entered in the **snmpd** entry. An **snmpd** entry can contain single or multiple variables.

The **snmpdv1** agent sets the **snmpd** specific parameters immediately upon reading them. If the values are invalid, the **snmpdv1** agent ignores them. If the **snmpdv1** agent encounters an invalid field in the entry, processing is terminated for that entry and the **snmpdv1** agent logs an EXCEPTIONS message if logging is enabled.

### smux Entry

The smux entry specifies configuration information for SMUX associations between the **snmpdv1** agent and SMUX peer clients. See example 6 for a sample entry. A smux entry must be in the following format:

**smux ClientOID Password IPAddress NetMask**

The following definitions apply to the smux entry:

| Item             | Description                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ClientOID</i> | Specifies the unique object identifier in dotted numeric notation of the SMUX peer client. The <i>ClientOID</i> must match the <i>ObjectID</i> specified in the <i>/etc/snmpd.peers</i> file.                         |
| <i>Password</i>  | Specifies the password that the <b>snmpdv1</b> agent requires from the SMUX peer client to authenticate the SMUX association. The <i>Password</i> must match the <i>Password</i> in the <i>/etc/snmpd.peers</i> file. |
| <i>IPAddress</i> | The hostname, or IPv4 address in dotted notation, or IPv6 address of the host on which the SMUX peer client is running.                                                                                               |
| <i>NetMask</i>   | Specifies a network mask in dotted decimal notation for the specified IPv4 address, or a prefix length in the range of 0 through 128 for the specified IPv6 address.                                                  |

The minimum specification for the smux entry is:

**smux ClientOID Password**

The default values for this minimum smux entry are:

| Item             | Description     |
|------------------|-----------------|
| <i>IPAddress</i> | 127.0.0.1       |
| <i>NetMask</i>   | 255.255.255.255 |

Fields to the right of the minimum entry are optional, with the limitation that no fields to the left of a specified field are omitted. Any information to the right of *NetMask* is ignored. If no password is specified, there is no confirmation for the SMUX association. If neither the *IPAddress* nor *NetMask* are specified, the SMUX association is limited to the local host.

In the case of an invalid smux entry, the **snmpdv1** agent logs an EXCEPTIONS message if logging is enabled and the **snmpdv1** agent ignores that smux entry.

### sysLocation and sysContact Entry

The sysLocation and sysContact entries specify the values of the **sysLocation** and **sysContact** variables. The entry is specified in the following format:

```
sysLocation "Austin, Texas, USA, XYZ, Bld 905, 5C-11"
sysContact "Bill Roth, Amber Services, 1-512-849-3999"
```

The first part of the entry specifies the variable to be set, **sysLocation** or **sysContact**. The second part is a quoted character string representing the variable's value. The length of this string should not exceed 256 characters. If more than one entry is in the file, the last entry is used to define the variable. If there is not an entry for a particular variable, the value is defined to be the NULL string. If there is not a quoted string after the variable name, the first word on the line is used as the value. If there is nothing after the variable name, the NULL string is assumed.

The **snmpdv1** daemon uses the defined configuration file, whether it is the default file or specified from the command line, to save and read variables. The daemon does not need to be refreshed to get these new variables.

**Note:** Since these variables are settable, the **snmpdv1** daemon writes to the configuration file to update these variables on a set request. If you are editing the file and a set request changes the variables, the set request could be lost when the edited file is saved. This can be avoided by shutting down the daemon to change the configuration file, or by using the **snmpinfo** command to set the variable through normal methods.

Comments are specified by a # (pound sign) character and can be located anywhere in the **snmpd.conf** file. A comment begins at the # character and continues to the end of the line.

**Note:** It does not matter in which order the specific configuration entries for community, traps, views, logging, **snmpd**, and smux are placed in the **snmpd.conf** file. There is no order dependency for the various entries.

## Examples

### 1. Example of community entries in the **snmpd.conf** file:

```
Community specifications
community public
community private 192.100.154.7 255.255.255.255 readWrite 1.17.2
community monitor 192.100.154.1 255.255.255.0 readWrite 1.17.2
community private oilers
community simple giants
community test 0.0.0.0 0.0.0.0 none
community nobody 0.0.0.0 255.255.255.255 readWrite 1.17.35
community ipv6test 0::0 0
community ipv6monitor 2000:1:1:1:209:6bff:feae:6d67 64 readWrite 1.17.2
```

The first entry exemplifies the minimum required specification for a community entry. The IP address defaults to 0.0.0.0. The network mask defaults to 0.0.0.0. The permissions default to readOnly. The view defaults to the entire MIB tree. This configuration enables the **snmpdv1** agent to accept all readOnly requests under the community name `public` regardless of the IP address. Write or set requests are rejected.

The second entry limits the **snmpdv1** agent to accept `readWrite` requests under the community name `private` only from IP address 192.100.154.7 for MIB variables that are associated with the view name 1.17.2.

The third entry enables the **snmpdv1** agent to accept `readWrite` requests under the community name `monitor` from all IP addresses that start with 192.100.154, as indicated by the network mask, for all MIB variables that are associated with the view name 1.17.2.

The fourth entry sets the network mask to the default 255.255.255.255 and the permissions to the default, `readOnly`. This configuration enables the **snmpdv1** agent to accept `readOnly` requests under the community name `private` from the host named `oilers` for the entire MIB tree. The reuse of the community name `private` is independent of the usage in the second example entry.

The fifth entry sets the network mask to the default 255.255.255.255 and the default permissions to `readOnly`. This configuration enables the **snmpdv1** agent to accept `readOnly` requests for the entire MIB tree under the community name `simple` only from the host `giants`. Write or set requests are rejected.

The sixth entry causes the **snmpdv1** agent to reject all requests under the community name `test`, regardless of the IP address, because of the permission restriction of `none`.

The seventh entry causes the **snmpdv1** agent to reject all requests under the community name `nobody` because the network mask limits the IP address to entry 0.0.0.0, which is reserved and not available for a host.

The eighth entry causes the **snmpdv1** agent to accept all requests through the IPv6 network under the community name `ipv6test`.

The ninth entry causes the **snmpdv1** agent to accept `read` and `write` requests under the community name `ipv6monitor` from all IP addresses that start with 2000:1:1:1:209:6bff:feae:6d67, as indicated by the network prefix length for all MIB variables that are associated with the view name 1.17.2.

## 2. Example of trap entries in the **snmpd.conf** file:

```
Trap host notification specifications
trap traps 192.100.154.7
trap traps 129.35.39.233
trap events giants
trap public oilers 1.2.3 be
trap private 129.35.42.2101.2.4 7etrap events 2000:1:1:1:209:6bff:feae:6d67
```

The first entry specifies that the **snmpdv1** agent is to notify the host with IP address 192.100.154.7 of all traps generated. The community name embedded in the trap packet will be `traps`.

The second entry specifies that the **snmpdv1** agent is to notify the host with IP address 129.35.39.233 of all traps generated. The community name embedded in the trap packet will be `traps`.

The third entry specifies that the **snmpdv1** agent is to notify the host `giants` of all traps generated. The community name embedded in the trap packet will be `events`.

The fourth entry specifies that the **snmpdv1** agent is to notify the host `oilers` of all traps generated except for the `warmStart` trap. The community name embedded in the trap packet will be `public`. The `ViewName`, 1.2.3, is ignored.

The fifth entry specifies that the **snmpdv1** agent is to notify the host 129.35.42.210 of all traps generated except the `coldStart` trap. The community name embedded in the trap packet will be `private`. The `ViewName`, 1.2.4, is ignored.

The sixth entry specifies that the **snmpdv1** agent is to notify the IPv6 host 2000:1:1:1:209:6bff:feae:6d67 of all of the traps generated. The community name embedded in the trap packet will be `events`.

## 3. Examples of view entries in the **snmpd.conf** file:

```

View specifications
view 1.17.2 system enterprises view
view 1.17.35
view 2.10.1 iso.3

```

The first entry associates the view name 1.17.2 with the system, enterprises, and view MIB groups. A community name that is associated with view 1.17.2 will only be associated with the MIB variables in these three groups. Thus, a host that has read permissions with this community name association can only get values for MIB variables in these specified groups.

The second and third entries configure the **snmpdv1** agent to allow access to the entire MIB tree for hosts that have access privileges associated with these specified view names.

4. Examples of logging entries in the **snmpd.conf** file:

```

Logging specifications
logging /tmp/snmpdlog enabled
logging level=2 size=100000

```

These logging entries configure the **snmpdv1** agent to log messages at debug level 2 and below to the file named /tmp/snmpdlog. The size parameter limits the file size of the /tmp/snmpd log file to 100,000 bytes. When the log file reaches 100,000 bytes, the log file is rotated such that the full file is renamed to /tmp/snmpdlog.0 and the new log file is named /tmp/snmpdlog.

5. Example of snmpd entries in the **snmpd.conf** file:

```

snmpd parameter specifications
snmpd maxpacket=2048
snmpd querytimeout=120

```

The first snmpd entry limits the size of packets transmitted by the **snmpdv1** agent to 2048 bytes.

The second entry sets the querytimeout parameter to 120 seconds. This configures the **snmpdv1** agent to query all the interfaces known to the TCP/IP kernel every two minutes for status changes.

6. Examples of smux entries in the **snmpd.conf** file:

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 #gated

```

This smux entry configures the **snmpdv1** agent to allow the SMUX association only the **gated** SMUX peer client with no authentication. The SMUX peer must be running on the local host.

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 private #gated

```

This smux entry configures the **snmpdv1** agent to allow the SMUX association only the **gated** SMUX peer client having the passwordprivate. The SMUX peer must be running on the local host.

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 private 0.0.0.0 0.0.0.0

```

This smux entry configures the **snmpdv1** agent to allow the SMUX association only the **gated** SMUX peer client having the passwordprivate. The SMUX peer can be running on any host.

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 private 192.100.154.7 255.255.255.255

```

This smux entry configures the **snmpdv1** agent to allow the SMUX association only the **gated** SMUX peer client having the passwordprivate. The gated SMUX peer must be running on the host with IP address 192.100.154.7

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 private 192.100.154.1 255.255.255.0

```

This entry configures the **snmpdv1** agent to allow the SMUX association only the **gated** SMUX peer client having the password private. The gated SMUX peer can be running on any host in the network defined by 192.100.154.

```

smux configuration
smux 1.3.6.1.4.1.2.3.1.2.2 private 2000:1:1:1:209:6bff:feae:6d67 64

```

This entry configures the **snmpdv1** agent to allow the SMUX association with only the **gated** SMUX peer client that has the private password. The gated SMUX peer can be running on any IPv6 host in the network defined by 2000:1:1:1:209:6bff:feae:6d67.

**Note:** The SMUX peer client object identifier must be unique. Only *one* form of the preceding examples of smux entries for the gated SMUX peer client can be in the **snmpd.conf** file.

7. Example of sysLocation and sysContact entries in the **snmpd.conf** file:

```
Definitions for sysLocation and sysContact
sysLocation "Austin, Texas, USA, XYZ, Bld 905, 5C-11"
sysContact "Bill Roth, Amber Services, 1-512-849-3999"
```

These entries set the value for the **sysLocation** and **sysContact** variables.

## **snmpd.boots File**

### **Purpose**

Provides the boot and engine ID information for the **snmpdv3** agent.

### **Description**

The **snmpd.boots** file provides the boot and engine ID information for the **snmpdv3** agent. The file contains two elements: an **engineID**, and, **engineBoots**, the number of times that the **snmpv3** daemon has been started.

### **Syntax**

```
engineID engineBoots
```

The following list explains the variables in the syntax:

#### **engineID**

A string of 2 to 64 (must be an even number) hexadecimal digits. The engine identifier uniquely identifies the agent within an administrative domain. By default, the engine identifier is created using a vendor-specific formula and incorporates the IP address of the agent. However, users can choose to use any engine identifier that is consistent with the **snmpEngineID** definition in RFC 2271, and that is also unique within the administrative domain.

For the engineID that is associated with an IPv4 address, the first 8 hexadecimal digits represent a vendor enterprise ID obtained from the Internet Assigned Numbers Authority (IANA). For IBM, this ID is 00000002. The last 16 hexadecimal digits are determined by vendor-formula. For IBM, the formula follows these rules:

- The first two hexadecimal digits indicate the content of the next 14 hexadecimal digits.
- The string 00 indicates that the next 6 hexadecimal digits are zeros, followed by the IP address of the agent in the last 8 hexadecimal digits.
- The string 01 indicates that the next 6 hexadecimal digits contain a time stamp, followed by the IP address of the agent in the last 8 hexadecimal digits.

The agent is always used without a time stamp, so the engineID for an SNMP agent at IPv4 address 9.67.113.10 is 00000002 00000000 09 43 71 0A (spaces are added for clarity).

An engineID associated with an IPv6 address follows these rules:

- The first 4 octets 80000002, which are a hexadecimal value, is an IANA assigned enterprise number.
- The 5th octet 02, which is a hexadecimal value, indicates that it is an IP address.
- The 6th octet to the 31st octet are hexadecimal values of the 16 bytes IPv6 address.

For example, the engineID for an SNMP agent running on IPv6 address 2000:1:1:1:209:6bff:feae:6d67 is 80000002 02 20000010001000202096BFFFEAE6D67 (spaces are added for clarity).

### **engineBoots**

The number of times (in decimal) the agent has been restarted since the engineID was last changed.

#### **Note:**

1. engineID and engineBoots must be specified in order and on the same line.
2. Comments are specified in the file by starting the line with either an asterisk (\*) or a pound sign (#).
3. No comments are allowed between engineID and engineBoots values.
4. Only the first non-comment line is read. Subsequent lines are ignored.

### **Example**

The first string of numbers is the **engineID**, the second string is the number of times the **snmpv3** daemon has been started.

00000002000000000903E65F 0000000003

### **Files**

| Item            | Description                                    |
|-----------------|------------------------------------------------|
| etc/snmpd.boots | Provides boot and <b>engineID</b> information. |

## **snmpdv3.conf File**

### **Purpose**

Defines a sample configuration file for the **snmpdv3** agent.

### **Description**

An entry must be contained on one line (i.e., the newline character will be treated as the end of an entry). All of the entry definitions require that all fields on the entry are specified, either with a specific value or a dash (-) to denote the default value. If an error is detected processing an entry and no appropriate default value can be assumed, the entry will be discarded. Statements in the file are not order-dependent. However, if more than one DEFAULT\_SECURITY statement is found, the last one in the file is the one that is used. For more information on sample configuration, refer to the /usr/samples/snmpdv3/snmpdv3.conf file.

### **General Usage Rules**

- All values for an entry must be on the same line.
- All keys need to be regenerated using the pwtkey command in order for these sample entries to actually be used.

- In this sample, keys are generated for use with engine ID 00000002000000000943714F.
- Authentication keys were generated with password of `username + password`, such as `u1password`.
- Privacy keys were generated with password of `username + privpass`, such as `u1privpass`.
- Entries defined to use encryption support, which is available only as a separately orderable feature on the base AIX product, are included below but commented out.

Comments may be entered in the **snmpdv3.conf** file, with the following restrictions:

- Comments must begin with the pound sign (#) or asterisk (\*).
- Comments must begin in column 1. This allows the pound sign and asterisk to be used in names of users, views, etc.

## **USM\_USER entries**

Defines a user for the User-based Security Model (USM). Format is:

```
userName engineID authProto authKey privProto privKey keyType storageType
```

where

### **userName**

Indicates the name of the user for the User-based Security Model (USM) and must be unique to the SNMP agent. The **userName** is used as the security name for the User-based Security Model. The contents of this field will be used as the **securityName** value for other entries (such as the VACM\_GROUP entry) when the **securityModel** is USM. Valid value is:

- An octet string of 1 to 32 octets (characters).

There is no default value.

### **engineID**

Indicates the **engineID** of the authoritative side of the message. The **engineID** for the AIX SNMP agent is determined at agent initialization. It is either read in from the **SNMPD.BOOTs** file or it is generated automatically and stored in the **SNMPD.BOOTs** file. It can be retrieved dynamically by issuing a **get** request for object **snmpEngineID**. For **get**, **getbulk**, **set**, **response**, and **trap** messages, the authoritative side is the SNMP agent. For inform messages, the authoritative side is the notification receiver.

**Note:** The **engineID** is defined in RFC 2271.

Valid values are:

- An octet string of 1 to 32 octets (2 to 64 hex digits).
- A '-' (dash) indicates the default value.

The default value is the local SNMP agent's **engineID**.

### **authProto**

Indicates the authentication protocol to be used on authenticated messages on behalf of this user. Valid values are:

- **HMAC-MD5** - indicates HMAC-MD5.
- **HMAC-SHA** - indicates HMAC-SHA.
- **none** - indicates no authentication is to be done.
- '-' (dash) - indicates the default value.

A The default value is HMAC-MD5 (if an authentication key is specified; if no authentication key is specified, no authentication can be done for messages to/from this user).

### **authKey**

Indicates the authentication key to be used in authenticating messages on behalf of this

user. This field will be ignored when **authProto** is specified as none. The **keyType** field will indicate whether the key is localized or non-localized. Valid values are:

- An octet string of 16 bytes (32 hex digits) when authProto is HMAC-MD5.
- An octet string of 20 bytes (40 hex digits) when authProto is HMAC-SHA.
- A '-' (dash) indicates the default.

The default value is no key, indicating no authentication.

#### **privProto**

Indicates the privacy protocol to be used on encrypted messages on behalf of this user. Privacy can be requested only if authentication is also requested. If authentication is not requested, this field is ignored. Valid values are:

- **DES** - indicates CBC-DES (only with the additional encryption product).
- **none** - indicates no privacy.
- A '-' (dash) indicates default.

The default value is no privacy. No encryption will be done on messages to/from this user.

#### **privKey**

The privacy key to be used in authenticating messages to and from this user. This field will be ignored when **privProto** is specified or defaulted as none. The **keyType** field will indicate whether the key is localized or non-localized. Privacy can be requested only if authentication is also requested. If authentication is not requested, this field is ignored. The privacy key and the authentication key are assumed to have been generated using the same authentication protocol (HMAC-MD5 or HMAC-SHA). Valid values are:

- An octet string of 16 bytes (32 hex digits) if the key is localized or if the key is non-localized and the **authProto** is HMAC-MD5.
- An octet string of 20 bytes (40 hex digits) if the key is non-localized and the **authProto** is HMAC-SHA.
- The '-' (dash) indicates default.

Default value is no key, indicating no encryption.

#### **keyType**

Indicates whether the keys defined by authKey and privKey are localized or non-localized. Localized indicates that they have been generated with the appropriate engineID making the key usable only at one snmpEngine. Non-localized indicates the key may be used at different snmpEngines. The **authKey** and **privKey**, if both are specified, must both be localized or both be non-localized. This field is ignored if no authentication or privacy is requested. Valid values are:

- **L** - indicates keys are localized.
- **N** - indicates keys are non-localized.
- **'-'** (dash) indicates default Default value is localized.

#### **storageType**

Indicates the type of storage in which this definition is to be maintained. **StorageTypes** are defined in RFC1903. Valid values are:

- **nonVolatile** - indicates the entry definition will persist across reboots of the SNMP agent, but it can, however, be changed or even deleted by dynamic configuration requests.
- **permanent** - indicates the entry definition will persist across reboots of the SNMP agent; it can be changed but not deleted by dynamic configuration requests
- **readonly** - indicates the entry definition will persist across reboots of the SNMP agent; it cannot be changed or deleted by dynamic configuration requests. **readOnly** is not

permitted if the authentication protocol is not 'none' (because keys must be changeable per RFC 2274 definition of **usmUserStorageType**) .

- '-' (dash) - indicates default.

Default value is non-volatile.

## VACM\_GROUP entries

Defines a security group (made up of users or communities) for the View-based Access Control Model (VACM). Format is:

```
groupName securityModel securityName storageType
```

where:

### groupName

Indicates the group name for the View-based Access Control Model (VACM) and must be unique to the SNMP agent. Valid value is:

- An octet string of 1 to 32 octets (characters).

There is no default value.

### securityModel

Indicates the SNMP security model for this entry. When an SNMP message comes in, the **securityModel** together with the **securityName** are used to determine to which group the user (or community) represented by the **securityName** belongs. Valid values are:

'SNMPv1' - indicates community-based security using SNMPv1 message processing.

'SNMPv2c' - indicates community-based security using SNMPv2c message processing.

'USM' - indicates User-based Security Model. A '-' (dash) - indicates default. Default value is 'USM'.

### securityName

Indicates a member of this group. For community-based security, it will be a community name. For the User-based Security Model, it will be a user name. Valid values are:

- An octet string of 1 to 32 octets (characters) indicating a USM userName when securityModel is USM.
- An octet string of 1 to 32 octets (characters) indicating a community Name when securityModel is 'SNMPv1' or 'SNMPv2c'.

There is no default value.

### StorageType

As defined above on the **USM\_USER** definition.

## VACM\_VIEW entries

Defines a particular set of MIB data, called a view, for the View-based Access Control Model. Format is:

```
viewName viewSubtree viewMask viewType storageType
```

where:

### viewName

Indicates the textual name of the view for the View-based Access Control Model. View names do not need to be unique. Multiple entries with the same name together define one view. However, the **viewname**, together with the **subtree** object ID, must be unique to an SNMP engine. Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

### viewSubtree

Indicates the MIB object prefix of the MIB objects in the view. Valid values are:

- An object id of up to 128 sub-OIDs.
- A textual object name (or object prefix).
- A combination of textual object name followed by numeric sub-OIDs. The name must be found within the compiled MIB or in the logical extension to the MIB, the **MIBS.DATA** file.

There is no default value.

#### **viewMask**

Indicates a mask that specifies which of the sub-OIDs in the subtree are relevant. See RFC2275 for a definition of the viewMask. Valid values are:

- A hex string of up to 16 octets (up to 128 bits) where each bit indicates whether or not the corresponding sub-OID in the subtree is relevant.
- A '-' (dash) - indicates default.

The default value is a mask of all (meaning all sub-OIDs are relevant).

#### **viewType**

Indicates the type of the view definition. Valid values are:

- **included** - indicating the MIB objects identified by this view definition are within the view.
- **excluded** - indicating the MIB objects identified by this view definition are excluded from the view.
- A '-' (dash) - indicates default.

The default value is **included**.

#### **storageType**

As defined above on the **USM\_USER** definition.

### **VACM\_ACCESS entries**

Identifies the access permitted to different security groups for the View-based Access Control Model. Format is:

```
groupName contextPrefix contextMatch securityLevel, securityModel
readView writeView notifyView storageType
```

where:

#### **groupName**

Indicates the group name for the View-based Access Control Model (VACM) for which access is being defined. Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

#### **contextPrefix**

Indicates an octet string to be compared with the incoming **contextName** if the value specified for the **contextMatch** field is **prefix**. Note, however, that the SNMP agent in AIX supports MIB objects in only the local (null) context. Valid values are:

- An octet string of 1 to 32 octets (characters).
- A '-' (dash) - indicates default.

The default value is the null context ("").

#### **contextMatch**

Indicates whether the incoming **contextName** must be compared with (and match exactly) the entire **contextName** or whether only the first part of the **contextName** (up to the length of the indicated value of the **contextPrefix**) must match. Valid values are:

- **exact** - indicates entire **contextName** must match.

- **prefix** - indicates only the prefix of the **contextName** must match.
- A '-' (dash) - indicates the default.

The default value is exact.

#### **securityLevel**

Indicates the **securityLevel** for this entry. Used in determining which access table entry to use. Valid values are:

- **noAuthNoPriv** or 'none' - indicates no authentication or privacy protocols applied.
- **AuthNoPriv** or 'auth' - indicates authentication protocols applied but no privacy protocol is applied.
- **AuthPriv** or 'priv' - indicates both authentication and privacy protocols applied (If the additional encryption pack is not applied, this level can be configured but cannot actually be used).
- A '-' (dash) - indicates default.

The default value is **noAuthNoPriv**.

#### **securityModel**

Indicates the SNMP security model for this entry. Used in determining which access table entry to use. Valid values are:

- **SNMPv1** - indicates community-based security using SNMPv1 message processing.
- **SNMPv2c** - indicates community-based security using SNMPv2c message processing.
- **USM** - indicates User-based Security Model.
- A '-' (dash) - indicates default.

The default value is **USM**.

#### **readView**

Indicates the name of the view to be applied when read operations (**get**, **getnext**, **getbulk**) are performed under control of this entry in the access table. Valid values are:

- An octet string of 1 to 32 octets (characters) identifying a view defined by a **VACM\_VIEW** definition.
- A '-' (dash) - indicates default.

The default value is no view; no **readView** defined for members of this group.

#### **writeView**

Indicates the name of the view to be applied when write operations (set) are performed under control of this entry in the access table. Valid values are:

- An octet string of 1 to 32 octets (characters) identifying a view defined by a **VACM\_VIEW** definition.
- A '-' (dash) - indicates default.

The default value is no view; no **writeView** defined for members of this group.

#### **notifyView**

Indicates the name of the view to be applied when notify operations (**traps** or **informs**) are performed under control of this entry in the access table. Valid values are:

- An octet string of 1 to 32 octets (characters) identifying a view defined by a **VACM\_VIEW** definition.
- A '-' (dash) - indicates default.

Default value is no view; no **notifyView** defined for members of this group

## **NOTIFY entries**

Identifies management targets to receive notifications. Format is:

```
notifyName tag type storageType
```

where:

#### **notifyName**

Is a locally unique identifier for this notify definition. Valid values are:

- An octet string of 1 to 32 octets (characters)

There is no default value.

#### **tag**

Indicates a tag value to be compared with the values in the **tagLists** defined in the **snmpTargetAddrTable** (either on TARGET\_ADDRESS entries or via dynamic configuration). For each match of this tag with a value in the **tagLists** defined in the **snmpTargetAddrTable**, a notification may be sent. See RFC2273 for a definition of **SnmpTagValue**. Valid values are:

- An octet string of 1 to 255 octets (characters). No delimiters are allowed.
- A '-' indicates the default.

Default value is no tag value.

#### **type**

Indicates which type of notification should be generated. Valid values are:

- **trap** - an unconfirmed notification; notification sent with **trap** PDUs.
- A '-' (dash) - indicates the default.

Default value is **trap**.

### **TARGET\_ADDRESS**

Defines a management application's address and parameters to be used in sending notifications.

Format is:

```
targetAddrName tDomain tAddress tagList targetParams timeout retryCount storageType
```

where:

#### **targetAddrName**

Indicates a locally unique identifier for this target address definition. Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

#### **tDomain**

Indicates the transport type of the address indicated by **tAddress**. Valid values are:

- **UDP** - for UDP datagrams.
- A '-' (dash) - for the default value.

Default value is **UDP**.

#### **tAddress**

Indicates the transport address to which notifications are sent. Valid values are:

- A 1- to 21- octet string indicating the IP address and optionally the UDP port.

Form is

```
ip_address:port
```

IP address must be specified as a.b.c.d where a, b, c and d are in the range of 0 to 255.  
The port, if specified, must be in the range of 1 to 65535. Example:

```
9.37.84.48:162
```

The IP address may not be defaulted, but the port, if not specified, will default to 162.

**tagList**

Indicates a list of tag values which are used to select target addresses for a notification operation. RFC2273 contains the complete definition of **SnmpTagList** and **SnmpTagValue**. The AIX implementation accepts as valid values:

- An octet string of 1 to 255 octets (characters). No delimiters are allowed.
- '-' indicates the default.

The default value is an empty list.

**targetParams**

Indicates a TARGET\_PARAMETERS **paramsName** value that indicates which security and message processing is to be used in sending notifications to this target. Valid values are:

- An octet string of 1 to 32 octets (characters)

There is no default value.

**timeout**

Indicates the expected maximum round trip time for communicating with this target address (in 1/100ths of a second). **timeout** is used only for inform type notifications; it is not used for traps. Valid values are:

- An integer in the range of (0..2147483647) specifying the number of hundredths of a second for the timeout. Note, however, that this value is not used for notifications of type **trap**.
- '-' (dash) indicating the default.

Default value is 0, meaning no timeout value.

**retryCount**

Indicates the number of retries to be attempted when a response is not received for a generated message. **retryCount** is used only for inform type notifications; it is not used for traps. Valid values are:

- An interger in the range of (0 to 255), indicating the number of retries to be attempted. Note, however, that this value is not used for notifications of type **trap**.
- A '-' (dash) indicating the default.

Default value is 0, meaning no retry.

**TARGET\_PARAMETERS**

Defines the message processing and security parameters to be used in sending notifications to a particular management target. Format is:

`paramsName mpModel securityModel securityName securityLevel storageType`

where:

**paramsName**

A locally unique identifier for this target parameters definition. Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

**mpModel**

The message processing model to be used in sending notifications to targets with this parameter definition. Valid values are:

- **SNMPv1** - indicates SNMPv1.
- **SNMPv2c** - indicates SNMPv2c.
- **SNMPv3** - indicates SNMPv3.

There is no default value.

### **securityModel**

Indicates the security model to be used in sending notifications to targets with this parameter definition. Valid values are:

- **SNMPv1** indicates SNMPv1.
- **SNMPv2c** Indicates SNMPv2c.
- **USM** indicates User-based Security Model.

There is no default value.

### **securityName**

Identifies the principal (user or community) on whose behalf SNMP messages will be generated using this parameter definition. For community based security, this would be a community name. For USM, this would be a user name. Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

### **securityLevel**

Indicates the security level to be used in sending notifications to targets with this parameter definition. Valid values are:

- **noAuthNoPriv** or **none** - indicates no authentication or privacy protocols applied.
- **AuthNoPriv** or **auth** - indicates authentication protocols applied but no privacy protocol is applied.
- **AuthPriv** or **priv** - indicates both authentication and privacy protocols applied. (If the additional encryption pack is not applied, this level can be configured, but not actually used.)
- **'-' (dash)** - indicates default.

Default value is **noAuthNoPriv**.

## **NOTIFY\_FILTER\_PROFILE**

Associates a notification filter profile with a particular set of target parameters. The format of this parameter is as follows:

`targetParamsName profileName storageType`

The following list explains the meaning of the variables in the previous format:

- **targetParamsName**: Defines the message processing and security parameters to be used in sending notifications to a particular management target.
- **profileName**: A locally unique identifier for this profile name definition. The valid value for this parameter must be an octet string of 1 through 32 octets (characters). No default value is defined for this parameter.
- **storageType**: Indicates the type of storage in which this definition is to be maintained.

## **NOTIFY\_FILTER**

Determines whether particular management targets receive particular notifications. The format of this parameter is as follows:

`profileName filterSubtree filterMask filterType storageType`

The following list explains the meaning of the variables in the **NOTIFY\_FILTER** parameter's format:

- **profileName**: A locally unique identifier for this profile name definition. The valid value for this parameter must be an octet string of 1 through 32 octets (characters). No default value is defined for this parameter.
- **filterSubtree**: Indicates the MIB subtree. When the **filterSubtree** parameter is combined with the corresponding instance of **snmpNotifyFilterMask**, it defines a family of subtrees that are included in, or excluded from, the filter profile. The following values are valid:

- An object ID of up to 128 sub-object IDs
- A textual object name (or object prefix)
- A combination of textual object name followed by numeric sub-object IDs

The name must be found within the compiled MIB or in the logical extension to the MIB, the **MIBS.DEFS** file. There is no default value.

- **filterMask:** Indicates the bit mask in combination with the corresponding instance of **snmpNotifyFilterSubtree**. This parameter defines a family of subtrees that are included in, or excluded from, the filter profile. The valid values must be an octet string of 0 through 16 octets. The default value is an octet string with a length of zero.
- **filterType:** Indicates the type of the filter definition. The following values are valid:
  - **included:** Indicates the family of filter subtrees defined by this entry that are included in a filter.
  - **excluded:** Indicates the family of filter subtrees defined by this entry that are excluded from a filter.
  - **- (dash):** Indicates the default value.

The default value for this parameter is **included**.

- **storageType:** Indicates the type of storage in which this definition is to be maintained.

## COMMUNITY

Defines a community for community-based security.

By default, the AIX **snmpdv3** agent does not configure any default community name, including the **public** community name. The **snmpdv3** agent neither work with the IPv4 address nor with the IPv6 address unless any COMMUNITY entry is configured for the IPv4 and/or IPv6 address. The format is:

```
communityName securityName securityLevel netAddr netMask storageType
```

where:

### **communityName**

Indicates a community name for community-based security (SNMPv1 or # SNMPv2c).

Valid values are:

- An octet string of 1 to 32 octets (characters).

There is no default value.

### **securityName**

Indicates a **securityName** defined for this **communityName**. The **securityName** is the more generic term for the principal (user or community) for which other entries, such as VACM\_GROUP and TARGET\_PARAMETERS, are defined. Typically, the **securityName** would match **communityName** or, at least, there would be a one-to-one correspondence between **securityName** and **communityName**. (Until the community MIB support is implemented, the community name must match the securityName exactly.) Valid values are:

- An octet string of 1 to 32 octets (characters).
- '**-**' (dash) - indicates default.

The default value is **securityName** equal to the specified **communityName**.

### **securityLevel**

Indicates the security level to be applied when processing incoming or outgoing messages with this community name.

**Note:** When the **communityMIB** is implemented, **authNoPriv** will also be a valid level of security, but at the moment, it will be rejected because there is no way to store a

**securityLevel** to be associated with a **communityName**. When that happens, the following will be added to the list of valid values below:

- **authNoPriv** or **auth** - indicates authentication protocols applied.

Note that no additional authentication checking is done by specifying **auth**.

Authentication still involves verifying that the community name is being used by an IP address for which it has been defined and using the views defined for that entry.

However, allowing the specification of **auth** here does allow the system administrator to define a different set of views to be used if the same community name is defined with two different **securityNames** (each with a different **securityLevel**)

Valid values are:

- **noAuthNoPriv** or **none** - indicates no authentication or privacy protocols applied.
- '-' (dash) - indicates default.

Default value is **noAuthNoPriv**. Encryption is not supported on SNMPv1/SNMPv2c messages.

#### **netAddr**

A network address indicating the range of addresses for which this community name might be used. The following values are valid:

- An IPv4 network address in the form of a.b.c.d, where a, b, c, and d are in the range of 0 through 255. However, not all of the four octets are required. Also, 255.255.255.255 is not a valid network address.
- An IPv6 network address.

#### **netMask**

An IP address mask to be logically ANDed with the origin address of the incoming SNMP message. If the resulting value equals the value specified for **netAddr**, the incoming message is accepted. The following values are valid:

- A network address in the form of a.b.c.d, where a, b, c, and d are in the range of 0 through 255. However, not all of the four octets are required.
- A prefix length in the range of 0 through 128 for IPv6 address.

There is no default value.

#### **storageType**

As defined above on the **USM\_USER** definition (Note, until the community MIB is implemented, storage type values other than **readOnly** will be treated as **readOnly**; i.e., they cannot be changed dynamically.)

### **DEFAULT\_SECURITY**

Identifies the default security posture to be configured for the SNMP agent; additional security definitions defined by the use of the preceding eight entry definition types augment any default security configurations defined as a result of the **DEFAULT\_SECURITY** statement. Format is:

**securityPosture password privacy**

where:

#### **securityPosture**

Indicates the default security posture to be configured for the SNMP agent, as defined by Appendix A of RFC 2275 (and outlined below). Valid values are:

- **minimum-secure** - indicates the SNMP agent will be configured with the least secure default configurations
- **semi-secure** - indicates the SNMP agent will be configured with moderately secure default configurations.
- **no-access** - indicates the SNMP agent will be configured with no default configurations.

The default value is **no-access**.

#### **password**

Indicates the password to be used to generate authentication and privacy keys for user 'initial'. In the case that **no-access** is specified as the **securityPosture**, this keyword is ignored. Valid values are:

- An octet string of 8 to 255 octets (characters).
- '-' (dash) - indicating the default.

Default value is no password. Default only accepted if **securityPosture** is **no-access**.

#### **privacy**

Indicates whether or not encryption is to be supported for messages on behalf of user 'initial'. Valid values are:

- **Yes** - indicates privacy is supported for user 'initial' (only with the additional encryption product).
- **No** - indicates privacy is not supported for user **initial**.
- '-' (dash) - indicates default value.

Default value is no. If **no-access** is selected as the security posture, this value will be ignored.

Default security definitions based on the selected security posture:

#### **no-access**

No initial configurations are done.

#### **semi-secure**

The default (null) context is configured. If privacy is not requested, a default user is configured as if the following USM\_USER entry had been specified. USM\_USER initial- HMAC-MD5 none - N permanent where ### indicates the key generated from the password specified on the DEFAULT\_SECURITY entry. If privacy is requested (and available with the additional encryption product), a default user is configured as if the following USM\_USER entry had been specified: USM\_USER initial - HMAC-MD5 ### DES ### N permanent where ### indicates the key generated from the password specified on the DEFAULT\_SECURITY entry.

A default group is configured as if the following VACM\_GROUP entry had been specified:

VACM\_GROUP initial USM initial **readOnly**. Three default access entries are configured as if the following VACM\_ACCESS entries had been specified:

```
VACM_ACCESS initial - exact none. USM restricted - restricted readOnly.
VACM_ACCESS initial - exact auth. USM internet internet internet readOnly
VACM_ACCESS initial - exact priv. USM internet internet internet readOnly
Two default MIB views are configured as if the following
VACM_VIEW entries .had been specified:
VACM_VIEW internet internet - included readOnly
VACM_VIEW restricted system - included readOnly
VACM_VIEW restricted snmp - included readOnly
VACM_VIEW restricted snmpEngine - included readOnly
VACM_VIEW restricted snmpMPDStats - included readOnly
VACM_VIEW restricted usmStats - included readOnly
```

#### **minimum-secure**

The default (null) context is configured. If privacy is not requested, a default user is configured as if the following USM\_USER entry had been specified.: USM\_USER initial - HMAC-MD5 ### none - N permanent where ### indicates the key generated from the password specified on the DEFAULT\_SECURITY entry.

If privacy is requested (and available with the additional encryption product), a default user is configured as if the following USM\_USER entry had been specified: USM\_USER initial - HMAC-MD5 ### DES ### N permanent where ### indicates the key generated from the password specified on the DEFAULT\_SECURITY entry.

A default group is configured as if the following VACM\_GROUP entry had been specified:  
VACM\_GROUP initial USM initial **readOnly**.

Three default access entries are configured as if the following VACM\_ACCESS entries had been specified:

```
VACM_ACCESS initial - exact none USM restricted - restricted readOnly
VACM_ACCESS initial - exact auth USM internet internet internet readOnly
VACM_ACCESS initial - exact priv USM internet internet internet
```

#### **readOnly**

Two default MIB views are configured as if the following VACM\_VIEW entries had been specified:

```
VACM_VIEW internet internet - included readOnly
VACM_VIEW restricted internet - included readOnly
```

#### **logging**

Directs logging from the configuration file. Format is:

```
logging file=</path/filename> enabled|disabled
logging size=<limit> level=<debug level>
```

There can be no white spaces around the "=" in the file, size and level fields where </path/filename> specifies the complete path and filename of the log file. Valid values are: An octet string of 1 to 255 octets (characters). Default value is /var/tmp/snmpdv3.log  
enabled | disabled. Valid values are: 'enabled' - turns logging on; 'disabled' - turns logging off. Default value is 'enabled'.

#### **<limit>**

Specifies the maximum size in bytes of the specified **logfile**. Valid values are: '0' - meaning unlimited. An unsigned integer number in the unit of byte. Default value is 0.

#### **<debug level>**

Specifies the logging level. Valid values are: # 0, 1, 2, 3, or 4. Default value is 0.

```
logging file=/usr/tmp/snmpdv3.log enabled
logging size=0 level=0
```

#### **smux entry**

Sets the SMUX peer configuration parameters # Format is:

```
smux <client OIdentifier> <password> <address> <netmask>
```

Fields to the right of <client OIdentifier> are optional, with the limitation that no fields to the left of a specified field are omitted. Where <client OIdentifier> defines the unique object identifier in dotted decimal notation of the SMUX peer client. Valid values are: An unique object identifier in dotted decimal notation up to 128 sub-OIDs of that SMUX peer. There is no default value.

#### **<password>**

Specifies the password that **snmpd** requires from the SMUX peer client to authenticate the SMUX association. If no password is specified, there is no authentication for the SMUX association. Valid values are: An octet string of 8 to 255 octets (characters). Default value is null string

#### **<address>**

Identifies the host on which the SMUX peer client is running. The following values are valid:

- A host name of 1 through 80 characters or an IPv4 address that must be specified in the format of a.b.c.d, where a, b, c, and d are in the range of 0 through 255
- An IPv6 address.

The default value of the <address> member is 127.0.0.1

#### <netmask>

Specifies the network mask. Valid values are: network mask must be specified as a.b.c.d where a, b, c and d are in the range of 0 to 255. Default value is 255.255.255.255.

```
smux 1.3.6.1.4.1.2.3.1.2.1.2 gated_password # gated
```

Any SNMP agent configuration entries added by dynamic configuration (SET) requests get added to the end of the **snmpdv3.conf** file.

## **snmpmibd.conf File**

### Purpose

Defines the configuration parameters for **snmpmibd dpi2** sub-agent.

### Description

The **snmpmibd.conf** file provides the configuration information for the **snmpmibd dpi2** sub-agent. This file can be changed while the **snmpmibd dpi2** sub-agent is running. If the **refresh** command is issued, the **snmpmibd dpi2** sub-agent will reread this configuration file. The **snmpmibd dpi2** sub-agent must be under System Resource Control (SRC) for the **refresh** command to force the reread. To perform a reread, as root user, run:

```
refresh -s snmpmibd
```

### Keywords

The directives are specified in the form of <keyword>=<value>. The keyword is case-insensitive. The value passed is also case-sensitive.

#### **logFilename**

The name of the most recent log file. Less recent log files have the number 1 to (n - 1) appended to their names. The larger the number, the less recent the file.

#### **logFileSize**

The size of log files in K bytes. Maximum size of a log file. When the size of the most recent log file reaches this value, it is renamed and a new log file is created.

#### **numLogFiles**

The number of log files desired. The maximum value for **numLogFiles** is 4. A new file is created when the size of the log file is equal or more than the size specified by the keyword **logFileSize**. When the number of log files reaches the **numLogFiles** the log files start rotating.

#### **tracelevel**

The tracing/debug level.

```

8 = DPI level 1
16 = DPI level 2
32 = Internal level 1
64 = Internal level 2
128 = Internal level 3

```

Add the numbers for multiple trace levels

## Example

```

logFileName=/usr/tmp/snmpmibd.log
logFileSize=0
numLogFiles=0
tracelevel=0

```

## File

## socks5c.conf File

### Purpose

Contains mappings between network destinations and SOCKSv5 servers.

### Description

The **/etc/socks5c.conf** file contains basic mappings (between network destinations, hosts or networks, and SOCKSv5 servers) to use when accessing network destinations. It is an ASCII file that contains records for server mappings. Text that follows a pound character (#) is ignored until the end of the line. Each record is on a single line in the following format:

*destination* [/*prefixlength*] *server* [:*port*]

You must separate the fields with whitespace. Records are separated by new line characters. The fields and modifiers in a record have the following values:

| Item                | Description                                                                                                                                                                                                                                                                     |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>destination</i>  | Specifies a network destination. The <i>destination</i> variable may be either a name fragment or a numeric address (with optional <i>prefixlength</i> ). If <i>destination</i> is an address, it may be either IPv4 or IPv6.                                                   |
| <i>prefixlength</i> | If specified, indicates the number of leftmost (network order) bits of an address to use when comparing to this record. It is valid only if <i>destination</i> is an address. If not specified, all bits are used in comparisons.                                               |
| <i>server</i>       | Specifies the SOCKSv5 server associated with <i>destination</i> . If <i>server</i> is <b>NONE</b> (must be all uppercase), this record indicates that target addresses matching <i>destination</i> should not use any SOCKSv5 server; instead, it should be contacted directly. |
| <i>port</i>         | If specified, indicates the port to use when contacting <i>server</i> .                                                                                                                                                                                                         |

If a name fragment *destination* is present in **/etc/socks5c.conf**, all target addresses in SOCKSv5 operations will be converted into hostnames for name comparison (in addition to numeric comparisons with numeric records). The resulting hostname is considered to match if the last characters in the hostname match the specified name fragment.

When using this configuration information to determine the address of the appropriate SOCKSv5 server for a target destination, the *best* match is used. The *best* match is defined as follows:

- If *destination* is numeric, the most bits in the comparison (i.e., largest *prefixlength*) are used.
- If *destination* is a name fragment, the most characters in the name fragment are.

When both name fragment and numeric addresses are present, all name fragment entries are *better* than numeric address entries.

The following two implicit records are assumed as defaults for all destinations not specified in **/etc/socks5c.conf**:

```
0.0.0.0/0 NONE #All IPv4 destinations; no associated server.
::/0 NONE #All IPv6 destinations; no associated server.
```

### **SOCKS5C\_CONFIG Environment Variable**

The **SOCKS5C\_CONFIG** environment variable enables the SOCKS library. To enable the library and to indicate that it uses the **socks5c.conf** file, you must set and export the variable to the pathname of the file, which is **/etc/socks5c.conf**. However, you can use a different configuration file by setting **SOCKS5C\_CONFIG** to the pathname of that file. If the specified file is not found, then by default the **socks5c.conf** file is used as a configuration file. If you set this variable to NULL, then SOCKS is not used and traditional network operations occur instead.

## **Security**

Access Control: This file should grant read (r) access to all users and grant write (w) access only to the root user.

### **Examples**

```
#Sample socks5c.conf file
9.0.0.0/8 NONE #Direct communication with all hosts in the 9 network.
129.35.0.0/16 sox1.austin.ibm.com
ibm.com NONE #Direct communication will all hosts matching "ibm.com" (e.g. "aguila.austin.ibm.com")
```

#### **Related information:**

[socks5tcp\\_connect](#)

## **space File**

### **Purpose**

Describes the format of a disk space requirements file.

### **Description**

The **space** file is an ASCII file that gives information about disk space requirements for the target environment. It defines the maximum additional space a package requires (for example, for files that are installed with the **installf** command).

The generic format of a line in this file is:

```
pathname blocks inodes
```

Definitions for the fields are as follows:

| Item            | Description                                                                                                                                                     |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>pathname</i> | Specifies a directory name which may or may not be the mount point for a filesystem. Names that do not begin with a slash (/) indicate relocatable directories. |
| <i>blocks</i>   | Defines the number of disk blocks required for installation of the files and directory entries contained in the pathname (using a 512-byte block size).         |
| <i>inodes</i>   | Defines the number of inodes required for installation of the files and directory entries contained in the pathname.                                            |

## Examples

```
extra space required by config data which is
dynamically loaded onto the system
data 500 1
```

## .srf File

### Purpose

Contains all the text components with hypertext information embedded.

### Description

The .srf file is one of several intermediate files produced for each document by InfoCrafter. The .srf file is a binary file that contains all the text components with hypertext link information embedded.

### Files

| Item | Description                                                 |
|------|-------------------------------------------------------------|
| .srf | Contains text components with embedded linking information. |

### Related reference:

“.fig File” on page 100

## streamcmds File

### Purpose

Contains auditstream commands.

### Description

The /etc/security/audit/streamcmds file is an ASCII template file that contains the stream mode commands that are invoked when the audit system is initialized. The path name of this file is defined in the stream stanza of the /etc/security/audit/config file.

This file contains command lines, each of which is composed of one or more commands with input and output that may be piped together or redirected. Although the commands usually are one or more of the audit system commands (**auditcat**, **auditpr**, and, **auditselect**), this is not a requirement. The first command, however, should be the **auditstream** command.

When the audit system is initialized, the **audit start** command runs each command. No path name substitution is performed on \$trail or \$bin strings in the commands.

### Security

Access Control: This file should grant read (r) access to the root user and members of the audit group, and write (w) access to the root user only.

## Examples

1. To read all records from the audit device, select and format those that involve unsuccessful events, and print them on a line printer, include the following in the **/etc/security/audit/streamcmds** file:

```
/usr/sbin/auditstream | /usr/sbin/auditselect -e \
"result == FAIL" |/usr/sbin/auditpr -v > /dev/lpr0
```

This command is useful for creating a hard-copy trail of system security violations.

2. To read all records from the audit device that have audit events in the authentication class, format them, and display them on the system console. Include the following in the **/etc/security/audit/streamcmds** file:

```
/usr/sbin/auditstream -c authentication | \
/usr/sbin/auditpr -t0 -v > /dev/console
```

This command allows timely auditing of user authentication events.

## Files

## sysck.cfg File

### Purpose

Contains file definitions for the trusted computing base.

### Description

**Note:** The **sysck** command does not update this file. It is only updated by the **tcck** command.

The **/etc/security/sysck.cfg** file is a stanza file that contains definitions of file attributes for the trusted computing base. The name of each stanza is the pathname of a file, followed by a : (colon). Attributes are in the form *Attribute=Value*. Each attribute is ended with a new-line character, and each stanza is ended with an additional new-line character.

Each stanza can have one or more of the following attributes, and must have the **type** attribute:

| Item            | Description                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>acl</b>      | Defines the access control list of the file, including the SUID, SGID, and SVTX bits. The value is the <i>Access Control List</i> , in the format described in Access control lists in <i>Operating system and device management</i> . |
| <b>class</b>    | Defines a group of files for checking, deleting, or updating. A file can be in more than one class. The value is the <i>ClassName</i> [ <i>ClassName</i> ] parameter.                                                                  |
| <b>checksum</b> | Defines the checksum, as computed with the <b>sysck checksum</b> program. This attribute is valid only for regular files. The value is the output of the <b>sum -r</b> command, including spaces.                                      |
| <b>group</b>    | Defines the group name or numeric group ID, expressed as the <i>GroupName</i> or <i>GroupID</i> parameter.                                                                                                                             |
| <b>links</b>    | Defines the absolute paths that have hard links to this object. The value must be an absolute pathname, expressed as the <i>Path</i> , [ <i>Path</i> ...] parameter.                                                                   |

| Item         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mode</b>  | Defines the file mode, expressed as the <i>Flag</i> , <i>Flag ...</i> , <i>Pbits</i> parameters. The <i>Flag</i> parameter can contain the <b>SUID</b> , <b>SGID</b> , <b>SVTX</b> , and <b>tcb</b> mode attributes. The <i>Pbits</i> parameter contains the base file permissions, expressed either in octal form, such as 640, or symbolic form, such as <i>rw-r--</i> , <i>r--</i> . The order of the attributes in the <i>Flag</i> parameter is not important, but base permissions must be the last entry in the list. The symbolic form may include only read (r), write (w), and execute (x) access. If the <b>acl</b> attribute is defined in the stanza, the <b>SUID</b> , <b>SGID</b> , and <b>SVTX</b> mode attributes are ignored. For a typical mode specification, see the Examples section. |
| <b>owner</b> | Defines the name or numeric ID of the file owner, expressed as the <i>OwnerName</i> or the <i>OwnerID</i> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>size</b>  | Defines the size of the file in bytes. This attribute is valid only for regular files. The value is a decimal number. A VOLATILE value in the size field indicates that the size of the file will change (so no checksum value can be given).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>type</b>  | The type of object. Select one of the following keywords: <b>FILE</b> , <b>DIRECTORY</b> , <b>FIFO</b> , <b>BLK_DEV</b> , <b>CHAR_DEV</b> , or <b>MPX_DEV</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Stanzas in this file can be created and altered with the **sysck** command. Direct alteration by other means should be avoided, since other accesses may not be supported in future releases.

Attributes that span multiple lines must be enclosed in double quotes and have new line characters entered as \n.

Since device configuration and the **sysck.cfg** database are independent and are not integrated, there is no automatic addition of **sysck.cfg** entries when a device is added. Hence, given the automatic configuration of devices at boot time, it is the responsibility of the administrator to maintain **/etc/security/sysck.cfg**. This is also true in the case of mirrored rootvg, since **/dev/ipldevice** gets relinked dynamically to the other disk when the system is rebooted off the mirrored disk.

## Security

Access Control: This file should grant read (r) access to the root user and members of the security group, and write (w) access to the root user only. General users do not need read (r) access.

## Examples

1. A typical stanza looks like the following example for the **/etc/passwd** file:

```
/etc/passwd:
 type = file
 owner = root
 group = passwd
 mode = TCB,640
```

2. A typical mode specification looks like the following example for a program that is part of the trusted computing base, that is a trusted process, and that has the **setuid** attribute enabled:

```
mode = SUID,TP,TCB,rwxr-x---
OR
mode = SUID,TP,TCB,750
```

## Files

## syslog.conf File

### Purpose

Controls output of the **syslogd** daemon.

### Description

Each line must consist of two parts:

1. A selector to determine the message priorities to which the line applies.
2. An action. Each line can contain an optional part.
3. Rotation.

The fields must be separated by one or more tabs or spaces.

### Format

*msg\_src\_list* destination [rotate [size *sizek|m*] [files *files*] [time *timeh|d|w|m|y*] [compress] [archive *archive*]]

where *msg\_src\_list* is a semicolon separated list of *facility.priority* where:

*facility* all (except mark)

mark - time marks kern,user,mail,daemon, auth,....

*priority*

is one of (from high to low):

emerg/panic,alert,crit,err(or),warn(ing),notice,info,debug (meaning all messages of this priority or higher)

*destination*

is:

/filename - log to this file username [,username2...] - write to user(s)

@hostname - send to syslogd on this machine

\* - send to all logged in users

centralizedlog **LogSpaceName/LogStreamName** - send to the specified PowerHA pureScale® logstream

[rotate [size *sizek|m*] [files *files*] [time *timeh|d|w|m|y*] [compress] [archive *archive*]] is:

If *destination* is a regular file and the word *rotate* is specified, then the *destination* is limited by either *size* or *time*, or both. The *size* value causes the *destination* to be limited to *size*, with *files* files kept in the rotation. The backup filenames are created by appending a period and a number to *destination*, starting

with .0. The *time* value causes the *destination* to be rotated after *time*. If both *time* and *size* are specified, then logfiles will be rotated once the logfile size exceeds *size* or the after *time*, whichever is earlier.

If the compress option is specified then the logfile names will be generated with a .Z extension. The files keyword will be applicable to the logfiles which are currently under rotation. For example, if we specify the compress option, then only file with .Z extension will be under rotation and the number of such files will be limited by *files* files. Any logfiles with an extension other than .Z will not be under the rotation scheme and thus will not be under the restriction of *files* files. Similarly if the compress option is removed then the files which have been generated with .Z extension will no longer be the part of rotation scheme and will not be limited by the *files* files.

The minimum size that can be specified is 10k. The minimum number of files that can be specified is 2. The default size is 1MB and the default for *files* is unlimited. Therefore, if only rotate is specified, the log will be rotated with *size* = 1m. The compress option means that rotated log files that are not in use will be compressed. The archive option will save rotated log files that are not in use to *archive*.

The default is not to rotate log files.

[perm [mode]] is:

If destination is a regular file, and the word *perm* is specified it means that rotated files is having the permission specified by mode.

[Filter [filename]] is:

If the destination is a regular file, and word *filter* is specified it means that the messages coming from the remote machine is logged on to the file specified with this keyword. The default is not to filter the remote messages and not to set the permissions on rotate log files.

**Requirement:** The letter indicating the unit must immediately follow the number in the syntax. For example, to specify the log rotation of every two days, the phrase time 2d is correct, but time 2 d is not.

**Note:** To use a PowerHA pureScale logstream destination, the PowerHA pureScale client fileset must be installed on the system and bindings information for the service named "CentralizedLogService" must be setup. The log space and log stream objects specified as the PowerHA pureScale logstream destination must exist.

**Note:** It is recommended not to use same destination file in multiple entries when using file rotation. The following example shows bad configuration, which should be avoided.

```
user.debug /var/log/syslog.out rotate size 100k files 4
user.notice /var/log/syslog.out rotate size 200k files 16
```

The proper configuration for the above case follows:

```
user.debug /var/log/syslog.debug.out rotate size 100k files 4
user.notice /var/log/syslog.notice.out rotate size 200k files 16
```

## Example

```
"mail messages, at debug or higher, go to Log file. File must exist."
"all facilities, at debug and higher, go to console"
"all facilities, at crit or higher, go to all users"
"user messages, at warning or higher, go to logstream"
mail.debug /usr/spool/mqueue/syslog
*.info /dev/console
*.crit *
user.warn centralizedlog CentralizedRAS/SyslogUserWarning
```

-or otherwise can have something like:

```
*.debug /var/log/syslog.debug100k.out rotate size 100k files 4
*.crit /var/log/syslog.dailycrit.out rotate time 1d
```

## Files

**syslogd** subroutine

## targets File

### Purpose

Defines iSCSI targets that will be accessed by the iSCSI software initiator.

### Description

The iSCSI **targets** file defines the name and location of the iSCSI targets that the iSCSI software initiator will attempt to access. This file is read any time the iSCSI software initiator driver is loaded.

Any line in this file that begins with "#" will be treated as a comment line and ignored. Other non-blank lines will define a target that the iSCSI software initiator will access. The "\" character may be used between fields as a line continuation character in order to make the file more readable.

The shipped version of this file contains comments that precisely define the format of the file. However, there are no default target names; the shipped file contains only comments. In order to use the iSCSI software initiator, the user must add target definitions to the file and then reload the iSCSI driver by running **cfgmgr** or by rebooting the system.

Each target is defined by three or four fields, as follows:

HostNameOrAddress PortNumber iSCSIName

or

HostNameOrAddress PortNumber iSCSIName CHAPSecret

The fields that define the target are:

#### HostNameOrAddress

This is the TCP/IP location of the target. The location may be specified by a TCP/IP address in dotted-decimal form, or by a host name which can be resolved to a valid TCP/IP address. The format for the IP Address is taken from RFC2373.

#### PortNumber

The TCP/IP port number on which the iSCSI target is listening. The standard port number for iSCSI is 3260, but some targets may allow customizing the port number, so this field must be specified.

#### iSCSIName

The iSCSI name of the target. This name must match the name defined to the target. Note that the iSCSI name will be converted to contain all lower case characters, in accordance with the iSCSI standards.

#### CHAPSecret

This optional field specifies the secret to be used by this initiator if CHAP authentication is required. The secret is a text string enclosed in double-quote characters. If this field is included in the target line, the iSCSI software initiator will offer CHAP authentication to the target, and if the

target requests such authentication, this value will be used as the secret during the authentication process. If the **CHAPSecret** field is not included in the target definition, the initiator will attempt to log in to the target without any authentication.

## Examples

1. **iSCSI Target without CHAP(MD5) authentication** - Assume the target is at address 192.168.3.2 and the valid port is 5003. The name of the target is iqn.com.ibm-4125-23wwt26. The target line would look like the following:

```
192.168.3.2 5003 iqn.com.ibm-4125-23wwt26
```

2. **iSCSI Target with CHAP(MD5) authentication** - Assume the target is at address 10.2.1.105 and the valid port is 3260. The name of the target is iqn.com.ibm-k167-42.fc1a and the CHAP secret is "This is my password." The target line would look like the following:

```
10.2.1.105 3260 iqn.com.ibm-k167-42.fc1a "This is my password."
```

3. **iSCSI Target with CHAP(MD5) authentication and line continuation** - Assume the target is at address iscsi.fake.com and the valid port is 3260. The name of the target is iqn.2003-01.com.ibm:00.fcd0ab21.shark128 and the CHAP secret is "123ismysecretpassword.fc1b". The target line would look like the following:

```
iscsi.fake.com 3260 iqn.2003-01.com.ibm:00.fcd0ab21.shark128 \
 "123ismysecretpassword.fc1b"
```

|--------------------|-------------------------|
| /etc/iscsi/targets | The iSCSI targets file. |

## Temporary (TM.\*) Files for BNU Purpose

Store data files during transfers to remote systems.

### Description

The Basic Networking Utilities (BNU) temporary (TM.\*) files store data files during transfers to remote systems.

After a data (D.\*) file is transferred to a remote system by the **uucico** daemon, the BNU program places the file in a subdirectory of the BNU spooling directory named **/var/spool/uucp/SystemName**. The *SystemName* directory is named for the computer transmitting the file. The BNU program creates a temporary data file to hold the original data file.

The full path name of the temporary data file is a form of the following:

**/var/spool/uucp/SystemName/TM.xxPID.000**

where the *SystemName* directory is named for the computer sending the file, and **TM.xxPID.000** is the name of the file; for example, **TM.00451.000**. The *PID* variable is the process ID of the job.

The **uucico** daemon normally deletes all temporary files when they are no longer needed. However, temporary files can also be removed using the **uucleanup** command with the **-T** flag.

## Files

## Workload Manager .times File

### Purpose

Defines time ranges for configurations in a configuration set.

### Description

Time ranges will appear in the configuration set files. These files are attribute files where the stanzas are the configuration names, and the only attribute is the time range. No default record is allowed (useless and confusing). A missing time range attribute stands for the default time range, which means always outside the other defined time ranges if any.

### Time Coherency Checks

It is mandatory that the time ranges do not overlap within a single file. In doing so, it would not be possible to find which is the right config to use. The union of all time ranges must cover all times. The default time range will help for ensuring this.

**Note:** It might not be possible to make changes to a correct file that result in another correct file without having intermediate incorrect file contents from this coherency point of view, due to commands or SMIT making one change at a time. For this reason, the content of the file is copied to .running at Workload Manager explicit update time.

### Syntax

This syntax applies to configuration set files and to **confsetcntrl** command, wherever a time range is given. SMIT and Web-based System Manager provide a more convenient way to select or enter a time range. A time range is specified as a range of days with 0 representing Sunday and 6 representing Saturday, and in 24 hour format, with hours and minutes specified. A default time range, which will include all time ranges not otherwise specified, is indicated by a single minus sign (-).

Specification:

```

<time-range>: -
<time-range>: <weekday-range>,<time-of-the-day-range>
<time-range>: <weekday-range>
<time-range>: <time-of-the-day-range>
<weekday-range>: <weekday>-<weekday>
<weekday-range>: <weekday>
<weekday>: 0 through 6 for Sunday through Saturday
<time-of-the-day-range>: <time-of-the-day>-<time-of-the-day>
<time-of-the-day>: <hour>.<minute>
<hour>: 0 through 23
<minute>: 0 through 59

```

**Note:**

1. A colon is accepted to separate hours and minutes instead of dot, provided that the field is quoted (colon has a special meaning in attributes file format).
2. Value 24 is correct for ending <hour> if <minute> is null.
3. For convenience and for command parameters only, <weekday> may be specified with the name or the abbreviation of the day of the week as they appear in the output of **locale day** or **locale abday** commands, taking into account the current user locale (LC\_TIME). This is not appropriate for attribute files which do not have a defined locale.

**Example**

```
conf1: time = -
conf2: time = "1-5,8:00-17:00"
conf2: time = "6-0,14:00-17:00"
conf3: time = "22:00-6:00"
```

**Files**

| Item         | Description                                         |
|--------------|-----------------------------------------------------|
| \$HOME/.time | Specifies the complete path name of the .time file. |

**unix.map File****Purpose**

Defines the operating system identity used for service provider applications on the node by the UNIX host-based authentication (HBA) security mechanism.

**Description**

Applications that use the cluster security services library must obtain an identity from the security mechanisms supported by the library. These identities are specific to the individual security mechanisms supported by cluster security services. Because cluster security services supports multiple security mechanisms and multiple applications, the cluster security services library must be informed of which identity to use for an application when interacting with a specific security mechanism on its behalf.

The default security mechanism used by the cluster security services library is the HBA mechanism. The **unix.map** file defines the identities used by the core cluster applications when interacting with the HBA mechanism. The cluster security services library expects to locate this file in **/var/ct/cfg/unix.map** (preferred) or **/opt/rsct/cfg/unix.map** (default).

This file is ASCII-text formatted, and can be modified with a standard text editor. However, this file should not be modified unless the administrator is instructed to do so by the cluster software service provider. If this configuration file is to be modified, the default **/opt/rsct/cfg/unix.map** file should not be modified directly. Instead, the file should be copied to **/var/ct/cfg/unix.map**, and modifications should be made to this copy. The default configuration file should never be modified.

All entries within this file use the following format:

SERVICE:service\_name:user\_name\_running\_the\_service

**Attribute****Definition****SERVICE**

Required keyword

#### *service\_name*

Specifies the name commonly used to refer to the application. For example, this could be the name used by the system resource controller to refer to this application.

#### *user\_name\_running\_the\_service*

Specifies the operating system user identity used to execute the application process. It is the owner identity that would be seen for the application process in the **ps** command output.

## Security

- The default identity mapping definition file **/opt/rsct/cfg/ctsec\_map.global** is readable by all system users, but permissions prevent this file from being modified by any system user.
- When creating the override identity mapping definition files **/var/ct/cfg/ctsec\_map.global** and **/var/ct/cfg/ctsec\_map.local**, make sure that the files can be read by any system user, but that they can only be modified by the root user or other restrictive user identity not granted to normal system users.
- By default, these files reside in locally-mounted file systems. While it is possible to mount the **/var/ct/cfg** directory on a networked file system, this practice is discouraged. If the **/var/ct/cfg/ctsec\_map.local** file were to reside in a networked file system, any node with access to that networked directory would assume that these definitions were specific to that node alone when in reality they would be shared.

## Restrictions

This file should not be modified unless the administrator is instructed to do so by the cluster software service provider. Incorrect modification of this file will result in authentication failures for the applications listed in this file and possibly their client applications. If this configuration file is to be modified, the default **/opt/rsct/cfg/unix.map** file should not be modified directly. Instead, the file should be copied to **/var/ct/cfg/unix.map**, and modifications should be made to this copy. The default configuration file should never be modified.

## Examples

This example shows the default contents of the configuration file:

```
SERVICE:ctrmc:root
SERVICE:rmc:root
SERVICE:ctloadl:loadl
SERVICE:ctdpcl:root
SERVICE:ctpmd:root
```

## Location

### **/var/ct/cfg/unix.map**

Contains the **unix.map** file

## Files

### **/opt/rsct/cfg/unix.map**

Default location of the **unix.map** file

## updaters File for NIS

### Purpose

Updates NIS maps.

### Description

The **/var/yp/updaters** file is a makefile used for updating NIS maps. NIS maps can only be updated in a secure network; that is, one that has a **publickey** file. Each entry in the file is a make target for a

particular NIS map. For example, if there is an NIS map named `passwdbyname` that can be updated, there should be a make target named `passwdbyname` in the **updaters** file with the command to update the file.

The information necessary to make the update is passed to the **update** command through standard input. All items are followed by a new line except for actual bytes of key and actual bytes of data. The information passed is described below:

- Network name of client wishing to make the update (a string)
- Kind of update (an integer)
- Number of bytes in key (an integer)
- Actual bytes of key
- Number of bytes in data (an integer)
- Actual bytes of data

After getting this information through standard input, the command to update the map determines whether the user is allowed to make the change. If the user is not allowed, the **update** command exits with the `YPERR_ACCESS` status. If the user is allowed to make the change, the command should make the change and exit with a status of 0. If any errors exist that may prevent the **updaters** file from making the change, the command should exit with the status that matches a valid NIS error code described in the `rpcsvc/ypclnt.h` file.

## **user File**

### **Purpose**

Contains extended user attributes.

### **Description**

The `/etc/security/user` file contains extended user attributes. This is an ASCII file that contains attribute stanzas for users. The **mkuser** command creates a stanza in this file for each new user and initializes its attributes with the default attributes defined in the `/usr/lib/security/mkuser.default` file.

Each stanza in the `/etc/security/user` file is identified by a user name, followed by a : (colon), and contains attributes in the form *Attribute=Value*. Each attribute value pair is ended by a new-line character, and each stanza is ended by an additional new-line character. For an example of a stanza, see the Examples section.

The file supports a default stanza. If an attribute is not defined for a user, the default value for the attribute is used.

### **Attributes**

If you have the proper authority, you can set the following user attributes:

| Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>account_locked</code> | Indicates if the user account is locked. Possible values include:<br><br><b>true</b> The user's account is locked. The values yes, true, and always are equivalent.<br>The user is denied access to the system.<br><br><b>false</b> The user's account is not locked. The values no, false, and never are equivalent.<br>The user is allowed access to the system. This is the default value.                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>admin</code>          | Defines the administrative status of the user. Possible values are:<br><br><b>true</b> The user is an administrator. Only the root user can change the attributes of users defined as administrators.<br><br><b>false</b> The user is not an administrator. This is the default value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>admgroups</code>      | Lists the groups the user administers. The <i>Value</i> parameter is a comma-separated list of group names. For additional information on group names, see the <b>adms</b> attribute of the <i>/etc/security/group</i> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>auditclasses</code>   | Lists the user's audit classes. The <i>Value</i> parameter is a list of comma-separated classes, or a value of ALL to indicate all audit classes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>auth1</code>          | Lists additional mandatory methods for authenticating the user. The <b>auth1</b> attribute has been deprecated and may not be supported in a future release. The <b>SYSTEM</b> attribute should be used instead. The authentication process will fail if any of the methods specified by the <b>auth1</b> attribute fail.<br><br>The <i>Value</i> parameter is a comma-separated list of <i>Method;Name</i> pairs. The <i>Method</i> parameter is the name of the authentication method. The <i>Name</i> parameter is the user to authenticate. If you do not specify a <i>Name</i> parameter, the name of the user being authenticated is used.                                                                                                                                                 |
| <code>auth2</code>          | Valid authentication methods for the <b>auth1</b> and <b>auth2</b> attributes are defined in the <i>/etc/security/login.cfg</i> file.<br><br>Lists additional optional methods for authenticating the user. The <b>auth2</b> attribute has been deprecated and may not be supported in a future release. The <b>SYSTEM</b> attribute should be used instead. The authentication process will not fail if any of the methods specified by the <b>auth2</b> attribute fail.<br><br>The <i>Value</i> parameter is a comma-separated list of <i>Method;Name</i> pairs. The <i>Method</i> parameter is the name of the authentication method. The <i>Name</i> parameter is the user to authenticate. If you do not specify a <i>Name</i> parameter, the name of the user being authenticated is used. |
| <code>core_compress</code>  | Enables or disables core file compression. Valid values for this attribute are On and Off. If this attribute has a value of On, compression is enabled; otherwise, compression is disabled. The default value of this attribute is Off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>core_path</code>      | Enables or disables core file path specification. Valid values for this attribute are On and Off. If this attribute has a value of On, core files will be placed in the directory specified by <b>core.pathname</b> (the feature is enabled); otherwise, core files are placed in the user's current working directory. The default value of this attribute is Off.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>core.pathname</code>  | Specifies a location to be used to place core files, if the <b>core_path</b> attribute is set to On. If this is not set and <b>core_path</b> is set to On, core files will be placed in the user's current working directory. This attribute is limited to 256 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>core_naming</code>    | Selects a choice of core file naming strategies. Valid values for this attribute are On and Off. A value of On enables core file naming in the form <code>core.pid.time</code> , which is the same as what the <b>CORE_NAMING</b> environment variable does. A value of Off uses the default name of <b>core</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>daemon</code>         | Indicates whether the user specified by the <i>Name</i> parameter can execute programs using the <b>cron</b> daemon or the <b>src</b> (system resource controller) daemon. Possible values are:<br><br><b>true</b> The user can initiate <b>cron</b> and <b>src</b> sessions. This is the default.<br><br><b>false</b> The user cannot initiate <b>cron</b> and <b>src</b> sessions.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>dce_export</code>     | Allows the DCE registry to overwrite the local user information with the DCE user information during a DCE export operation. Possible values are:<br><br><b>true</b> Local user information will be overwritten.<br><br><b>false</b> Local user information will not be overwritten.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Item                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>dictionlist</b>                 | Defines the password dictionaries used by the composition restrictions when checking new passwords.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                    | The password dictionaries are a list of comma-separated, absolute path names that are evaluated from left to right. All dictionary files and directories must be write-protected from all users except root. The dictionary files are formatted one word per line. The word begins in the first column and terminates with a new-line character. Only 7-bit ASCII words are supported for passwords. If text processing is installed on your system, the recommended dictionary file is the <i>/usr/share/dict/words</i> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>minloweralpha</b>               | Defines the minimum number of lower case alphabetic characters that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number. Range: 0 to PW_PASSLEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>minupperalpha</b>               | Defines the minimum number of upper case alphabetic characters that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number. Range: 0 to PW_PASSLEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>mindigit</b>                    | Defines the minimum number of digits that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number. Range: 0 to PW_PASSLEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>minspecialchar</b>              | Defines the minimum number of special characters that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number. Range: 0 to PW_PASSLEN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>efs_adminks_access</b>          | Defines the <b>efs_admin</b> keystore location. Only one value is possible:<br><br><b>file</b> Keystore is stored in the <i>/var/efs/efs_admin/</i> file.<br><b>Note:</b> This attribute is valid only if the system is EFS-enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>efs_allowksmodechangebyuser</b> | Defines whether the user can change the mode or not. The following values are possible:<br><br><b>yes</b> The user can change the keystore mode (using the <b>efskeymgr</b> command).<br><b>no</b> The user cannot change the keystore mode (using the <b>efskeymgr</b> command).<br><b>Note:</b> This attribute is valid only if the system is EFS-enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>efs_file_algo</b>               | Defines the algorithm that is used to generate the file protection key. The following values are possible:<br><ul style="list-style-type: none"><li>• <b>AES_128_CBC</b></li><li>• <b>AES_192_CBC</b></li><li>• <b>AES_256_CBC</b></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>efs_initialks_mode</b>          | <b>Note:</b> This attribute is valid only if the system is EFS-enabled.<br>Defines the initial mode of the user keystore. The following values are possible:<br><br><b>guard</b> When a keystore is in root guard mode, the keys that are contained in this keystore cannot be retrieved without the correct password of this keystore.<br><b>admin</b> When a keystore is in root admin mode, the keys that are contained in this keystore can be retrieved with the EFS (Encrypted File System) admin key.<br><b>Notes:</b> <ul style="list-style-type: none"><li>• This attribute is valid only if the system is EFS-enabled.</li><li>• This is the initial mode of the keystore. Changing this value using the <b>chuser</b> command, the <b>chggroup</b> command, or the <b>chsec</b> command, or with manual editing, does not change the mode of the keystore. Use this attribute only when you are creating the keystore and do not use it again until the keystore is deleted and a new one is created. To change the keystore mode, use the <b>efskeymgr</b> command.</li></ul> |
| <b>efs_keystore_access</b>         | Defines the user keystore location. The following values are possible:<br><br><b>none</b> There is no keystore.<br><b>file</b> Keystore is stored in the <i>/var/efs/users/</i> directory.<br><b>Note:</b> This attribute is valid only if the system is EFS-enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Item                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>efs_keystore_algo</code> | <p>Defines the algorithm that is used to generate the user private key when the keystore is created. The following values are possible:</p> <ul style="list-style-type: none"> <li>• <b>RSA_1024</b></li> <li>• <b>RSA_2048</b></li> <li>• <b>RSA_4096</b></li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>• This attribute is valid only if the system is EFS-enabled.</li> <li>• Changing the value of this attribute using the <b>chuser</b> command, the <b>chgroup</b> command, or the <b>chsec</b> command, or with manual editing, does not regenerate the private key. Use this attribute only when you are creating the keystore and do not use it again until the keystore is deleted and a new one is created. To change the algorithm for the keys, use the <b>efskeymgr</b> command.</li> </ul> |
| <code>expires</code>           | Identifies the expiration date of the account. The <i>Value</i> parameter is a 10-character string in the <i>MMDDhhmmyy</i> form, where <i>MM</i> = month, <i>DD</i> = day, <i>hh</i> = hour, <i>mm</i> = minute, and <i>yy</i> = last 2 digits of the years 1939 through 2038. All characters are numeric. If the <i>Value</i> parameter is 0, the account does not expire. The default is 0. See the <b>date</b> command for more information.                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>histexpire</code>        | Designates the period of time (in weeks) that a user cannot reuse a password. The value is a decimal integer string. The default is 0, indicating that no time limit is set.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>histsize</code>          | Designates the number of previous passwords a user cannot reuse. The value is a decimal integer string. The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>login</code>             | Indicates whether the user can log in to the system with the <b>login</b> command. Possible values are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                | <b>true</b> The user can log in to the system. This is the default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                                | <b>false</b> The user cannot log in to the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>logintimes</code>        | Specifies the times, days, or both, the user is allowed to access the system. The value is a comma-separated list of entries of the following form:<br><code>[!] :time-time<br/>      -or-<br/>[!]day[-day] [:time-time]<br/>      -or-<br/>[!]date[-date] [:time-time]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                | The <i>day</i> variable must be one digit between 0 and 6 that represents one of the days of the week. A 0 (zero) indicates Sunday and a 6 indicates Saturday.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                | The <i>time</i> variable is 24-hour military time (1700 is 5:00 p.m.). Leading zeroes are required. For example, you must enter 0800, not 800. The <i>time</i> variable must be four characters in length, and there must be a leading colon (:). An entry consisting of only a time specification applies to every day. The start hour of a time value must be less than the end hour.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                | The <i>date</i> variable is a four digit string in the form <i>mmdd</i> . <i>mm</i> represents the calendar month and <i>dd</i> represents the day number. For example 0001 represents January 1. <i>dd</i> may be 00 to indicate the entire month, if the entry is not a range, or indicating the first or last day of the month depending on whether it appears as part of the start or end of a range. For example, 0000 indicates the entire month of January. 0600 indicates the entire month of June. 0311-0500 indicates April 11 through the last day of June.                                                                                                                                                                                                                                                              |
|                                | Entries in this list specify times that a user is allowed or denied access to the system. Entries not preceded by an ! (exclamation point) allow access and are called ALLOW entries. Entries prefixed with an ! (exclamation point) deny access to the system and are called DENY entries. The ! operator applies to only one entry, not the whole restriction list. It must appear at the beginning of each entry.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>loginretries</code>      | Defines the number of unsuccessful login attempts allowed after the last successful login before the system locks the account. The value is a decimal integer string. A zero or negative value indicates that no limit exists. Once the user's account is locked, the user will not be able to log in until the system administrator resets the user's <code>unsuccessful_login_count</code> attribute in the <code>/etc/security/lastlog</code> file to be less than the value of <code>loginretries</code> . To do this, enter the following:                                                                                                                                                                                                                                                                                     |
|                                | <code>chsec -f /etc/security/lastlog -s username -a \<br/>unsuccessful_login_count=0</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Item               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>maxage</b>      | Defines the maximum age (in weeks) of a password. The password must be changed by this time. The value is a decimal integer string. The default is a value of 0, indicating no maximum age.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>maxexpired</b>  | Defines the maximum time (in weeks) beyond the <b>maxage</b> value that a user can change an expired password. After this defined time, only an administrative user can change the password. The value is a decimal integer string. The default is -1, indicating no restriction is set. If the <b>maxexpired</b> attribute is 0, the password expires when the <b>maxage</b> value is met. If the <b>maxage</b> attribute is 0, the <b>maxexpired</b> attribute is ignored.                                                                                                                                                                                                             |
| <b>maxrepeats</b>  | Defines the maximum number of times a character can be repeated in a new password. Since a value of 0 is meaningless, the default value of 8 indicates that there is no maximum number. The value is a decimal integer string.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>minage</b>      | Defines the minimum age (in weeks) a password must be before it can be changed. The value is a decimal integer string. The default is a value of 0, indicating no minimum age.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>minalpha</b>    | Defines the minimum number of alphabetic characters that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>mindiff</b>     | Defines the minimum number of characters required in a new password that were not in the old password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>minlen</b>      | Defines the minimum length of a password. The value is a decimal integer string. The default is a value of 0, indicates no minimum length. The maximum value allowed is <b>PW_PASSLEN</b> attribute. This attribute is determined by the <b>minalpha</b> attribute value added to the <b>minother</b> attribute value. If the sum of these values is greater than the <b>minlen</b> attribute value, the minimum length is set to the result.<br>Note: The <b>PW_PASSLEN</b> attribute is defined in <b>/usr/include/userpw.h</b> . The value of the <b>PW_PASSLEN</b> attribute is determined by the system-wide password algorithm that is defined in <b>/etc/security/login.cfg</b> . |
|                    | The minimum length of a password is determined by the <b>minlen</b> attribute and should never be greater than the <b>PW_PASSLEN</b> attribute. If the <b>minalpha attribute + minother attribute</b> is greater than the <b>PW_PASSLEN</b> attribute, then the <b>minother</b> attribute is reduced to <b>PW_PASSLEN attribute - minalpha attribute</b> .                                                                                                                                                                                                                                                                                                                               |
| <b>minother</b>    | Defines the minimum number of non-alphabetic characters that must be in a new password. The value is a decimal integer string. The default is a value of 0, indicating no minimum number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>projects</b>    | Defines the list of projects that the user's processes can be assigned to. The value is a list of comma-separated project names and is evaluated from left to right. The project name should be a valid project name as defined in the system. If an invalid project name is found on the list, it will be reported as an error by the <b>user</b> command.                                                                                                                                                                                                                                                                                                                              |
| <b>pwdchecks</b>   | Defines the password restriction methods enforced on new passwords. The value is a list of comma-separated method names and is evaluated from left to right. A method name is either an absolute path name or a path name relative to <b>/usr/lib</b> of an executable load module.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>pwdwarntime</b> | Defines the number of days before the system issues a warning that a password change is required. The value is a decimal integer string. A zero or negative value indicates that no message is issued. The value must be less than the difference of the <b>maxage</b> and <b>minage</b> attributes. Values greater than this difference are ignored, and a message is issued when the <b>minage</b> value is reached.                                                                                                                                                                                                                                                                   |
| <b>registry</b>    | Defines the authentication registry where the user is administered. It is used to resolve a remotely administered user to the local administered domain. This situation may occur when network services unexpectedly fail or network databases are replicated locally. Example values are <b>files</b> or <b>NIS</b> or <b>DCE</b> .                                                                                                                                                                                                                                                                                                                                                     |
| <b>rlogin</b>      | Permits access to the account from a remote location with the <b>telnet</b> or <b>rlogin</b> commands. Possible values are:<br><br><b>true</b> The user account can be accessed remotely. This is the default <b>rlogin</b> value.<br><b>false</b> The user account cannot be accessed remotely.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>su</b>          | Indicates whether another user can switch to the specified user account with the <b>su</b> command. Possible values are:<br><br><b>true</b> Another user can switch to the specified account. This is the default.<br><b>false</b> Another user cannot switch to the specified account.                                                                                                                                                                                                                                                                                                                                                                                                  |

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sugroups</b> | Lists the groups that can use the <b>su</b> command to switch to the specified user account. The <i>Value</i> parameter is a comma-separated list of group names, or a value of ALL to indicate all groups. An ! (exclamation point) in front of a group name excludes that group. If this attribute is not specified, all groups can switch to this user account with the <b>su</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYSTEM</b>   | Defines the system authentication mechanism for the user. The value may be an expression describing which authentication methods are to be used or it may be the keyword NONE.<br><br>The <b>SYSTEM</b> mechanism is always used to authenticate the user, regardless of the value of the <b>auth1</b> and <b>auth2</b> attributes. If the <b>SYSTEM</b> attribute is set to NONE, authentication is only performed using the <b>auth1</b> and <b>auth2</b> attributes. If the <b>auth1</b> and <b>auth2</b> attributes are blank or ignored, as with the TCP socket daemons ( <b>ftpd</b> , <b>rexecd</b> and <b>rshd</b> ), no authentication will be performed.<br><br>The method names <b>compat</b> , <b>files</b> and <b>NIS</b> are provided by the security library. Additional methods may be defined in the file <b>/usr/lib/security/methods.cfg</b> . |
|                 | Specify the value for <b>SYSTEM</b> using the following grammar:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                 | <pre> "SYSTEM"      ::= EXPRESSION EXPRESSION    ::= PRIMITIVE                     "(" EXPRESSION ")"                     EXPRESSION OPERATOR EXPRESSION PRIMITIVE     ::= METHOD                     METHOD "["RESULT"]" RESULT        ::= "SUCCESS"   "FAILURE"   "NOTFOUND"                     "UNAVAIL"   "*" OPERATOR      ::= "AND"   "OR" METHOD         ::= "compat"   "files"   "NONE"                     [a-z,A-Z,0-9]*</pre>                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                 | An example of the syntax is:<br><code>SYSTEM = "DCE OR DCE[UNAVAIL] AND compat"</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>tpath</b>    | Indicates the user's trusted path status. The possible values are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                 | <ul style="list-style-type: none"> <li><b>always</b>    The user can only execute trusted processes. This implies that the user's initial program is in the trusted shell or some other trusted process.</li> <li><b>notsh</b>     The user cannot invoke the trusted shell on a trusted path. If the user enters the secure attention key (SAK) after logging in, the login session ends.</li> <li><b>nosak</b>    The secure attention key (SAK) is disabled for all processes run by the user. Use this value if the user transfers binary data that may contain the SAK sequence. This is the default value.</li> <li><b>on</b>        The user has normal trusted path characteristics and can invoke a trusted path (enter a trusted shell) with the secure attention key (SAK).</li> </ul>                                                                 |
| <b>ttys</b>     | Lists the terminals that can access the account specified by the <i>Name</i> parameter. The <i>Value</i> parameter is a comma-separated list of full path names, or a value of ALL to indicate all terminals. The values of RSH and REXEC also can be used as terminal names. An ! (exclamation point) in front of a terminal name excludes that terminal. If this attribute is not specified, all terminals can access the user account. If the <i>Value</i> parameter is not ALL, then /dev/pts must be specified for network logins to work.                                                                                                                                                                                                                                                                                                                   |
| <b>umask</b>    | Determines file permissions. This value, along with the permissions of the creating process, determines a file's permissions when the file is created. The default is 022.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The following attributes are valid only in the Trusted AIX system. See Trusted AIX in *Security* for more information. Valid values for each attribute are defined in the **/etc/security/enc/LabelEncodings** file for the system. Values must be defined in quotation marks (" ") if they have white spaces.

| Item         | Description                                                                                                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>minsl</b> | Defines the minimum sensitivity clearance level (SCL).<br><b>Note:</b> The <b>defsl</b> value for the user dominates the <b>minsl</b> value.                                                              |
| <b>maxsl</b> | Defines the maximum SCL.<br><b>Note:</b> The <b>maxsl</b> value dominates the <b>defsl</b> value for the user.                                                                                            |
| <b>defsl</b> | Defines the default sensitivity level that the user is assigned during login.<br><b>Note:</b> The <b>defsl</b> value dominates the <b>minsl</b> value and is dominated by the <b>maxsl</b> value.         |
| <b>mintl</b> | Defines the minimum integrity clearance level.<br><b>Note:</b> The <b>deftl</b> value for the user dominates the <b>mintl</b> value.                                                                      |
| <b>maxtl</b> | Defines the maximum integrity clearance level.<br><b>Note:</b> The <b>maxtl</b> value dominates the <b>deftl</b> value for the user.                                                                      |
| <b>deftl</b> | Defines the default integrity clearance level that the user is assigned during login.<br><b>Note:</b> The <b>deftl</b> value dominates the <b>mintl</b> value and is dominated by the <b>maxtl</b> value. |

## Changing the user File

You should access this file through the commands and subroutines defined for this purpose. You can use the following commands to change the **user** file:

- **chuser**
- **lsuser**
- **mkuser**
- **rmuser**

The **mkuser** command creates an entry for each new user in the **/etc/security/user** file and initializes its attributes with the attributes defined in the **/usr/lib/security/mkuser.default** file. To change attribute values, use the **chuser** command. To display the attributes and their values, use the **lsuser** command. To remove a user, use the **rmuser** command.

To write programs that affect attributes in the **/etc/security/user** file, use the subroutines listed in the related information section.

## Security

### Access Control

This file should grant read (r) access only to the root user and members of the security group. Access for other users and groups depends upon the security policy for the system. Only the root user should have write (w) access.

### Auditing Events

| Event               | Information |
|---------------------|-------------|
| <b>S_USER_WRITE</b> | file name   |

## Examples

1. A typical stanza looks like the following example for user dhs:

```
dhs:
 login = true
 rlogin = false
 ttys = /dev/console
 sugroups = security,!staff
 expires = 0531010090
 tpath = on
 admin = true
 auth1 = SYSTEM,METH2;dhs
```

2. To allow all ttys except /dev/tty0 to access the user account, change the ttys entry so that it reads as follows:

```
ttys = !/dev/tty0,ALL
```

## Files

| Item                             | Description                                                            |
|----------------------------------|------------------------------------------------------------------------|
| /etc/group                       | Contains the basic group attributes.                                   |
| /etc/passwd                      | Contains the basic user attributes.                                    |
| /etc/security/audit/config       | Contains audit system configuration information.                       |
| /etc/security/environ            | Contains the environment attributes of users.                          |
| /etc/security/group              | Contains the extended attributes of groups.                            |
| /etc/security/limits             | Contains the process resource limits of users.                         |
| /etc/security/login.cfg          | Contains configuration information for user log in and authentication. |
| /etc/security/passwd             | Contains password information.                                         |
| /usr/lib/security/mkuser.default | Contains default user configurations.                                  |
| /etc/security/user               | Contains extended user attributes.                                     |
| /etc/security/lastlog            | Contains last login information.                                       |
| /etc/security/enc/LabelEncodings | Contains label definitions for the Trusted AIX system.                 |

## user.roles File

### Purpose

Contains the list of roles for each user.

### Description

The **/etc/security/user.roles** file contains the list of roles for each user. This is an ASCII file that contains a stanza for system users. Each stanza is identified by a user name followed by a : (colon) and contains attributes in the form *Attribute=Value*. Each attribute pair ends with a newline character as does each stanza.

This file supports a default stanza. If an attribute is not defined, either the default stanza or the default value for the attribute is used.

A stanza contains the following attribute:

| Item  | Description                               |
|-------|-------------------------------------------|
| roles | Contains the list of roles for each user. |

For a typical stanza, see the "Examples" section.

Typically, the **/etc/security/user.roles** stanza contains an entry for every user and a list of data associated with that user. The roles database does not require an entry per user. The size of each entry is one line.

The **user.roles** file is kept separately from the **/etc/security/user** file for performance reasons. Several commands scan this database, so system performance increases with smaller files to scan (especially on systems with large numbers of users).

## Changing the **user.roles** File

You should access this file through the commands and subroutines defined for this purpose. You can use the following commands to change the **user.roles** file:

- **chuser**
- **lsuser**
- **mkuser**

The **mkuser** command creates an entry in the **/etc/security/user.roles** file for each new user when the **roles** attribute is used. To change the attribute values, use the **chuser** command with the **roles** attribute. To display the attributes and their values, use the **lsuser** command with the **roles** attribute.

To write programs that affect attributes in the **/etc/security/user.roles** file, use the subroutines listed in Related Information.

## Security

Access Control: This file grants read and write access to the root user, and read access to members of the security group.

## Examples

A typical stanza looks like the following example for the **username** role:

```
username:
 roles = role1,role2
```

## Files

| Item                               | Description                               |
|------------------------------------|-------------------------------------------|
| <b>/etc/security/roles</b>         | Contains the list of valid roles.         |
| <b>/etc/security/user.roles</b>    | Contains the list of roles for each user. |
| <b>/etc/security/smitacl.group</b> | Contains the group ACL definitions.       |

## **vfs** File

### Purpose

Describes the virtual file systems (VFS) installed on the system.

### Description

The **/etc/vfs** file describes the virtual file systems installed on the system. The name, type number, and file-system helper program are among the types of information listed in the file. Commands, such as the **mount** command, the **fsck** command (file system check), and the **mkfs** command (make file system), use this information.

The **vfs** file is an ASCII file, with one record per line. The following are examples of the three types of lines in the **vfs** file:

- Comments

```
This is a comment.
Comments begin with a # (pound sign).
Blank lines are ignored.
The following example only locally defines the default vfs file.
```

- General control

```
%defaultvfs jfs nfs
```

The fields for the **%defaultvfs** control line are:

| Item               | Description                                          |
|--------------------|------------------------------------------------------|
| <b>%defaultvfs</b> | Identifies the control line.                         |
| jfs                | Indicates the default local virtual file system.     |
| nfs                | Indicates the remote virtual file system (optional). |

- Entries

| #Name | Type | Mount Helper    | Fs. helper               |
|-------|------|-----------------|--------------------------|
| jfs   | 3    | none            | /sbin/helpers/v3fshelper |
| nfs   | 2    | /etc/nfsmnthevp | none                     |
| cdrfs | 5    | none            | none                     |

The comments are in text for explanatory purposes. The general control lines, which are designated by a % (percent) character, configure the actions of the following commands:

- mount**
- umount**
- mkfs**
- fsck**
- fsdb**
- df**
- ff**

For example, a line like **%defaultvfs** indicates the default local virtual file system is used if no VFS is specified by the **mount** command or in the **/etc/filesystems** file. The entry is the name of the VFS as indicated in the file. If a second entry is listed on the same line, it is taken to be the default remote VFS. The **%defaultvfs** control line may leave off the remote VFS specification.

The VFS entries take the following form:

| Item       | Description                                                                                                                                                                                                                             |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name       | Canonical name of this type of virtual file system.                                                                                                                                                                                     |
| type       | Decimal representation of the virtual file system type number for the VFS.                                                                                                                                                              |
| mnt_helper | Path name of the mount helper program of this VFS. If a mount helper is not required, the entry should be displayed as none. If this path name does not begin with a slash, it is relative to the <code>/sbin/helpers</code> directory. |
| fs_helper  | Path name of the file system helper program of this VFS. If a file system helper is not required, the entry should be none. If this path name does not begin with a slash, it is relative to the <code>/sbin/helpers</code> directory.  |

## Workload Manager classes File

### Purpose

Contains the definition of Workload Manager (WLM) superclasses or subclasses for a given configuration.

### Description

The **classes** file in the `/etc/wlm/Config` directory describes the superclasses of the WLM configuration, *Config*. If the superclass *Super* of this configuration has subclasses defined, these subclasses are defined in the file `/etc/wlm/Config/Super/classes`.

Some attributes apply to only superclasses or to only subclasses. The description of the **classes** file uses the terms *class* or *classes* when a statement applies to both superclasses and subclasses.

The **classes** file is organized into stanzas. Each stanza names a WLM class and contains attribute-value pairs that describe characteristics of the class.

### Attributes

Each stanza names a WLM class. Class names can contain only upper- and lowercase letters, numbers, and underscores. They are limited to 16 characters in length. The only names that have special meaning to the system are Default, Shared, Unclassified, Unmanaged, and System. You cannot use Unclassified and Unmanaged as class names. The superclasses Default, Shared, and System are always defined. The subclasses Default and Shared are always defined.

The following attributes are defined in the **classes** file:

| Item               | Description                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tier</b>        | Specifies the position of the class in the hierarchy of resource limitation desirability for all classes. A class with a lower tier value will be more favored than a class with a higher tier value. The tier value is a number from 0 to 9. If this attribute is not defined, it defaults to 0.               |
| <b>inheritance</b> | If the <b>inheritance</b> attribute is given the value Yes, the children of processes in this class remain in the class upon execution, regardless of the automatic assignment rules in effect. If this attribute is given No, the normal assignment rules apply. If not defined, the attribute defaults to No. |
| <b>localshm</b>    | Indicates whether memory segments accessed by processes in different classes remain local to the class they were initially assigned to or if they go to the Shared class. The possible value is Yes or No. If not specified, the default is No.                                                                 |
| <b>authuser</b>    | Specifies the user name of the user allowed to assign processes to this class. If not defined, this attribute defaults to the empty string ("").                                                                                                                                                                |
| <b>authgroup</b>   | Specifies the group name of the group of users allowed to assign processes to this class. If not defined, the attribute defaults to the empty string.                                                                                                                                                           |
| <b>rset</b>        | Names the resource set to which the processes in the class have access. If the attribute is not defined, it defaults to an empty string, meaning that the class has access to all the resources on the system.                                                                                                  |
| <b>adminuser</b>   | Specifies the user name of the user allowed to administer the subclasses of this superclass. If not defined, the attribute defaults to the empty string.                                                                                                                                                        |
|                    | This attribute is valid only for superclasses.                                                                                                                                                                                                                                                                  |
| <b>admingroup</b>  | Specifies the group name of the group of users allowed to administer the subclasses of this superclass. (Primary group of users should match with this group name.) If this attribute is not defined, it defaults to the empty string.                                                                          |
|                    | This attribute is valid only for superclasses.                                                                                                                                                                                                                                                                  |
| <b>delshm</b>      | If set to "yes", or if a killed process due to a virtual memory limit is the last process referencing a shared segment, the segment is deleted. The default is to not delete the shared segments (value set to "no").                                                                                           |
| <b>vmenforce</b>   | When a class reaches its virtual memory limit, if <b>vmenforce</b> is set to "class", all of the processes classified to the faulting class are killed. If <b>vmenforce</b> is set to "proc" (default), then only the process that pushes the usage past the virtual memory limit is killed.                    |

The attributes that have not been explicitly set by a WLM administrator using any of the administration tools (file editing, command line, or SMIT) are omitted in the property files.

The default values mentioned above are the system defaults and can be modified using a special stanza named "default."

## Files

| Item           | Description                                                   |
|----------------|---------------------------------------------------------------|
| <b>classes</b> | Defines the superclasses or subclasses of a WLM configuration |

## Security

The WLM property files defining the superclasses of a WLM configuration must have write permission only for the root user. The WLM property files defining the subclasses of a superclass must have write permission for the adminuser and admingroup for the superclass.

If there is no adminuser for the superclass, the files should be owned by root. If no admingroup exists for a superclass, the WLM property files for the superclass should be group "system" with no write permission for group.

## Example

1. The following entry at the beginning of the **classes** file modifies the default values for the **tier** and **inheritance** attributes so that if they are not defined for some (or all) of the classes specified in the file, the **tier** value is 1 and the **inheritance** value is Yes:

```
default:
tier = 1
inheritance = "yes"
```

The scope of these user-defined default values is limited to the file where they appear. For instance, if the above default stanza appears in the top-level **classes** file of a configuration, it does not affect the default values for the **classes** files defining the subclasses of the various superclasses.

2. The following is an example of a typical **/etc/wlm/Config/classes** file:

```
* system defined classes
* All attributes to default value
* Attribute values can be specified
*
Default:
System:
Shared:
* User defined classes
*
Super1:
 inheritance = "yes"
 adminuser = "bob"
 authgroup = "devlt"
Super2:
 tier = 4
 localshm = "yes"
 admingroup = "sales"
 authuser = "sally"
 rset = "part1"
```

**Note:** The asterisk (\*) is a comment character. Comments are added by directly editing the file. However, when you use the command line, or SMIT to create, modify, or delete classes, the comments are removed.

## Workload Manager limits File

### Purpose

Describes the minimum and maximum limits for the resources allocated to superclasses or subclasses of a WLM configuration.

### Description

The **limits** file in the **/etc/wlm/Config** describes the resource limits for the superclasses of the WLM configuration **Config**. If the superclass **Super** of this configuration has subclasses defined, the resource limits for the subclasses are defined in the file **/etc/wlm/Config/Super/limits**.

The limits at the superclass level represent a percentage of the total amount of resources available on the system and the limits at the subclass level represent a percentage of the resource made available to the parent superclass. Despite this difference, the description of resource limits is relevant to both a superclass and a subclass.

The **limits** file is organized into stanzas that are named after WLM classes and contain attribute-value pairs specifying the minimum and maximum resource limit allocated to the class for the various resources. The attribute names identify the resource. For each resource, the following values must be provided:

- Minimum limit (expressed here as *m*)
- Soft maximum limit (expressed here as *SM*)
- Hard maximum limit (expressed here as *HM*)

The limits are expressed as percentages. Both the minimum and maximum limits are each a number between 0 and 100. The hard maximum must be greater than or equal to the soft maximum, which in turn must be greater than or equal to the minimum. When the limits are not specified for a class or a resource type, the system defaults to 0 for the minimum and 100 for both the soft and hard maximum.

Use the following format for defining the limit values:

```
attribute_name = m%-SM%,HM%
```

In the AIX operating system you can also specify per-process and per-class total limits. These are hard limits and can be specified in the following format:

```
attribute_name = <value> [unit]
```

The valid range of values for each attribute, as well as their default and allowed units are described in *Operating system and device management*.

## Attributes

Each stanza names a WLM class that must exist in the **classes** file at the corresponding level (superclass or subclass).

The following attributes are defined in the **limits** file:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CPU              | Represents the CPU limits for the class                                                                                                                                                                                                                                                                                                                                                                                    |
| memory           | Represents the physical memory limits for the class                                                                                                                                                                                                                                                                                                                                                                        |
| diskIO           | Represents the disk I/O limits for the class                                                                                                                                                                                                                                                                                                                                                                               |
| totalConnectTime | The maximum amount of time a login session in the class can stay active. This is specified as an integer with the units intended (s for seconds, m for minutes, h for hours, d for days, and w for weeks). As a user approaches this connection time limit, WLM will send warning messages. When the limit is reached, the user will be notified and the login session will be terminated.                                 |
| totalCPU         | The total amount of CPU time allowed for each process in the class. This is specified as an integer with the units intended (s for seconds, m for minutes, h for hours, d for days, and w for weeks).                                                                                                                                                                                                                      |
| totalDiskIO      | The total amount of DiskIO allowed for each process in the class. This is specified as an integer with the units intended (KB for kilobytes, MB for megabytes, TB for terabytes, PB for petabytes, and EB for exabytes).                                                                                                                                                                                                   |
| totalLogins      | The total number of login sessions simultaneously available in the class. If a user tries to log onto the system and the login shell would end up in a class that has reached the <b>totalLogins</b> limit, the login operation will fail. Also, if an operation would cause a login shell to be moved into a class that has reached the <b>totalLogins</b> limit, the operation will also fail.                           |
| totalProcesses   | The maximum number of processes allowed in the class. If an operation would result in a new process entering the class when the class has this many processes in it, the operation will fail.                                                                                                                                                                                                                              |
| totalThreads     | The maximum number of threads allowed in the class. If an operation would result in a new thread entering the class when the class has this many threads in it, the operation will fail. The total thread limit must be at least as large as the total process limit for a class. If a class has a total thread limit but no total process limit specified, the total process limit will be set to the total thread limit. |
| classVirtMem     | The maximum amount of virtual memory that a class can have at one time. This is specified as an integer with units intended (MB for megabytes, GB for gigabytes, TB for terabytes).                                                                                                                                                                                                                                        |
| procVirtMem      | The maximum amount of virtual memory that a process can have at one time. This is specified as an integer with units intended (MB for megabytes, GB for gigabytes, TB for terabytes).                                                                                                                                                                                                                                      |

The default values mentioned above are the system defaults and can be modified using a special stanza named "default."

Consider the following stanza at the beginning of the **limits** file:

```
default:
 CPU = 10%-50%,80%
 diskIO = 20%-60%,100%
```

This stanza modifies the default values of the limits for CPU and disk I/O so that if those attributes are not specified for some (or all) of the classes, their minimum, soft maximum, and hard maximum default to the values shown above. In this example, the default values for the physical memory limits (specified by the **memory** attribute) are still the system default—the minimum 0% and the soft and hard maximum each 100%.

Classes that use only default values for all the resource types can be omitted in the file.

## Security

The **limits** file defining the limits of the superclasses of a WLM configuration must have write permission for root only. The **limits** file defining the limits for the subclasses of a superclass must have write permission for the adminuser and admingroup for the superclass. If no adminuser exists for the superclass, the **limits** file should be owned by root. If no admingroup exists for a superclass, the file for the superclass should be owned by the "system" group and have no write permission for group.

## Example

The following is an example of a typical */etc/wlm/Config/limits* file:

```
* System Defined Classes
* In this example, the system administrator uses
* only default values for the System and Shared
* superclasses. The System class has a memory minimum of
* 1% by default - can be increased by system administrator
* The system administrator gives non default values
* only for the Default class:
*
System:
 memory = 1%-100%,100%
Default:
 CPU = 0%-50%,75%
 memory = 0%-25%,50%
*
* User defined classes
*
Super1:
 CPU = 10%-100%,100%
 memory = 20%-100%,100%
 diskIO = 0%-33%,50%
Super2:
 memory = 0%-20%,50%
 diskIO = 10%-66%,100%
```

**Note:** The asterisk (\*) is a comment character.

## Workload Manager rules File

### Purpose

Defines the automatic class assignment rules for the superclasses or subclasses of a given Workload Manager (WLM) configuration.

### Description

The **/etc/wlm/Config/rules** file describes the assignment rules for the superclasses of the WLM configuration *Config*. If the superclass *Super* of this configuration has subclasses defined, the assignment rules for the subclasses are defined in the file **/etc/wlm/Config/Super/rules**.

The assignment rules for the superclasses and subclasses are formatted the same.

The **rules** file is a standard text file. Each line represents an assignment rule for a specified class. Several assignment rules can exist at the same time for the same class. Each rule lists the name of a class and a list of values for some attributes of a process; these values are used as classification criteria. The various fields of a rule are separated by white spaces. For attributes that you do not define, represent them with a hyphen (-).

**Note:** Implicit rules exist for the default superclass and the default subclass of every superclass. These rules catch all processes that did not match any rules explicitly stated in the **rules** file. They apply to a WLM configuration regardless of whether they are explicitly stated.

### Assignment Rules

Assignment rules are made of the fields described below. When present, the following fields *must* appear in the order shown below. Order is important because the values are given to the field identified by its position in the string. Only the first three fields (**class**, **reserved**, and **user**) are mandatory. The remaining fields can be omitted if their values are hyphens.

For instance, the assignment rule

```
class1 - user1
```

is the same as the following:

```
class1 - user1 - - - -
```

The rule

```
class - - group1 - 32bit+fixed
```

is a valid rule equivalent to the following rule:

```
class - - group1 - 32bit+fixed -
```

But in the case of the rule `class1 - group1`, `group1` is interpreted as a user name because of its position in the string.

| Item                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>class</code>       | Contains the name of a class that is defined in the <code>class</code> file corresponding to the level of the <code>rules</code> file (superclass or subclass). Class names can contain only upper- and lowercase letters, numbers, and underscores and are limited to 16 characters in length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>reserved</code>    | No assignment rule can be specified for the system-defined classes "Unclassified," "Unmanaged," and "Shared."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>user</code>        | This field must be set to a hyphen (-)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>group</code>       | Contains either a hyphen or a list of valid group names (as defined in the <code>/etc/group</code> file). The list is composed of one or more names, separated by a comma (,). To exclude a group from the class, place an exclamation mark (!) before the name of that group. Use full Korn shell pattern-matching syntax to specify a wildcard pattern to match a set of group names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>application</code> | Contains either a hyphen or a list of application path names. This is the path name of the file executed by the processes to be included in the class. The value can be either a full path name or a wildcard pattern that matches a set of path names. The list is composed of one or more path names, separated by a comma. To exclude an application from the class, place an exclamation mark before the name of that application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>type</code>        | Contains either a hyphen or a list of attributes for the process. The following are possible values:<br><br><b>32bit</b> Indicates that the process is 32-bit<br><b>64bit</b> Indicates that the process is 64-bit<br><b>plock</b> Indicates that the process has called the <code>plock</code> subroutine to pin memory<br><b>fixed</b> Indicates that the process is fixed priority (SCHED_FIFO or SCHED_RR)<br><br>The value of the <code>type</code> field can be a comma-separated list of combinations of one or more of the values above. Within the combination, each item must be separated by a plus (+) sign. For example, the value <code>fixed,64bit+plock</code> indicates that any fixed priority process (whether 32- or 64-bit) matches. In addition, 64-bit processes calling the <code>plock</code> subroutine matches. But the value <code>fixed+64bit+plock</code> indicates a different rule criteria: only processes that are 64-bit, fixed, and that are calling the <code>plock</code> subroutine match the criteria.<br><br>The <b>32bit</b> value and <b>64bit</b> value mutually exclude each other. |
| <code>tag</code>         | May contain either a hyphen or a list of application tags. The list is composed of one or more application tag values separated by commas.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

When classifying a process, WLM attempts to match the values of the process attributes (`user`, `group`, `application`, `type`, and `tag`) with the values provided in the `rules` file. To match values, WLM uses the following criteria:

- If the value in the rule is a hyphen, any value of the corresponding process attribute is a match.
- If the value of a process attribute (other than the `type` attribute) appears in the list of values specified in the corresponding field in the rule and is not preceded by an exclamation mark, it is a match for the specified attribute.
- If the values of the process `type` attribute (`32bit/64bit, plock, fixed`) match all the values (separated by + signs) provided in the list for the `type` field in the rule, they are a match for the process type.
- The process is classified in the class specified in the `class` field of the rule if ALL the values of the process attributes match the values in the corresponding field of the rule.
- WLM scans the rules in the order in which they appear in the `rules` file and classifies the process in the class specified in the *first rule for which a match is detected*. Therefore, the order of the rules in the file is very important.

When classifying a process, WLM first scans the **rules** file for the superclasses of the current configuration to determine which superclass the process is assigned to. Then, WLM scans the **rules** file for this superclass to determine which subclass it assigns the process to.

Threads may also be assigned to a class if they have an application tag. They will be assigned using the same rules as the process. However, threads that do not have an application tag will remain assigned to their process' class.

## Groupings

As an improvement for the AIX operating system, you can now use attribute value groupings in the **rules** file. Attribute groupings can be used as element of a selection criteria in the **rules** file for superclasses or subclasses. For more information, syntax and examples, see the **groupings** file.

## Security

The file containing the assignment rules for the superclasses must have write permission for the root user only. The file containing the assignment rules for the subclasses of a superclass must have write permission for the adminuser and admingroup for the superclass. If no adminuser exists for the superclass, the file should be owned by root. If no admingroup exists for a superclass, the **rules** file for the superclass should be owned by the system group and have no write permission for group.

## Examples

1. The following is an example of a /etc/wlm/Config/rules file:

```
* This file contains the rules used by WLM to
* assign a process to a superclass
*
* class resvd user group application type tag
db1 - - - /usr/bin/oracle* - _DB1
db2 - - - /usr/bin/oracle* - _DB2
devlt - - dev - - -
 - - - - - -
VPs - bob,ted - - - -
acctg - - acct* - - -
System - root - - - -
Default - - - - - -
```

2. The following is an example of the **rules** file for the superclass **devlt** in the /etc/wlm/Config/devlt/ directory:

```
* This file contains the rules used by WLM to
* assign a process to a subclass of the
* superclass devlt
*
* class resvd user group application type tag
hackers - jim,liz - - - -
hogs - - - - 64bit+clock -
editors - !sue - /bin/vi,/bin/emacs - -
build - - - /bin/make,/bin/cc - -
Default - - - - - -
```

Note: The asterisk (\*) is a comment character.

## Files

| Item  | Description                                                                                  |
|-------|----------------------------------------------------------------------------------------------|
| rules | Defines the class assignment rules for the superclasses or subclasses of a WLM configuration |

## Workload Manager shares File

### Purpose

Contains the definition of the number of shares of all the resources allocated to superclasses or subclasses for a given configuration.

### Description

The **shares** file in the */etc/wlm/Config* directory describes the resource allocations for the superclasses of the WLM configuration named *Config*. If the superclass named *Super* of this configuration has subclasses defined, the resource allocations for the subclasses are defined in the file */etc/wlm/Config/Super/shares*.

The file is organized into stanzas that are named after WLM classes and contain attribute-value pairs specifying the number of shares allocated to the class for the various resources. The attribute names identify the resource. The shares value is either an integer between 1 and 65535 or a hyphen (-) to indicate that WLM does not regulate the class for the given resource. The hyphen is the system default.

### Attributes

Each stanza names a WLM class that must exist in the **classes** file at the corresponding level (superclass or subclass).

The following are class attributes defined in the **shares** file:

| Item   | Description                                                           |
|--------|-----------------------------------------------------------------------|
| CPU    | Specifies the number of CPU shares allocated to the class             |
| memory | Specifies the number of physical memory shares allocated to the class |
| diskIO | Specifies the number of disk I/O shares allocated to the class        |

The default values mentioned above are the system default and can be modified using a special stanza named "default."

Consider the following stanza at the beginning of the **shares** file:

```
default:
 CPU = 10
 diskIO = 4
```

This stanza defines the default values for the number of shares for CPU and disk I/O so that if the **CPU** and **diskIO** attributes are not specified for some or all of the classes specified, the attributes default to 10 and 4, respectively. In this example, the default value for physical memory is still a hyphen, meaning no regulation. Classes that use only default values for all the resource types can be omitted in the **shares** file.

## Security

The **shares** file must have write permission for root user only. The **shares** file for superclasses must have write permission for the adminuser and admingroup for the superclass.

If no adminuser exists for the superclass, the files should be owned by root. If no admingroup exists for a superclass, the **shares** file for the superclass should be owned by the system group and should have no write permission for group.

## Example

The following is an example of a typical */etc/wlm/Config/shares* file:

```
* System Defined Classes
* In this example, the system administrator uses
* only default values for the System
* and Shared
* superclasses, and those are omitted
* in the file
* The system administrator gives non
* default values
* only for the Default class:
*
Default:
 CPU = 5
 memory = 10
*
* User defined classes
*
Super1:
 CPU = 8
 memory = 20
 diskIO = 6
Super2:
 memory = 12
 diskIO = 6
```

**Note:** The asterisk (\*) is a comment character.

## xferstats File for BNU

### Purpose

Contains information about the status of file transfer requests.

## Description

The **/var/spool/uucp/.Admin/xferstats** file contains information about the status of each Basic Networking Utilities (BNU) file transfer request. The **xferstats** file contains:

- System name
- Name of the user requesting the transfer
- Date and time of the transfer
- Name of the device used in the transfer
- Size of the transferred file
- Length of time the transfer took

## Examples

Following is a typical entry in the **xferstats** file:

```
zeus!jim M (10/11-16:10:33) (C,9234,1) [-] -> 1167 / 0.100secs
```

A file was transferred by user **jim** to system **zeus** at 4:10 p.m. on the 11th of October. The file size was 1167 bytes and the transfer took 0.100 seconds to complete.

## xtab File for NFS

### Purpose

Contains entries for currently exported NFS directories.

## Description

The **/etc/xtab** file contains entries for directories that are currently exported. This file should only be accessed by programs using the **getexportent** subroutine. To remove entries from this file, use the **-u** flag of the **exportfs** command.

## Files

| Item          | Description                                                |
|---------------|------------------------------------------------------------|
| /etc/exports  | Lists the directories that the server can export.          |
| /etc/hosts    | Contains an entry for each host on the network.            |
| /etc/netgroup | Contains information about each user group on the network. |

## File Formats

Certain files in the operating system are required to have a specific format. The formats of the files that are provided with the operating system are discussed in the documentation for those files. If a file is generated by either the system or a user rather than provided on the distribution medium, it is discussed as a *file format* in this documentation. File formats often are also associated with header files that contain C-language definitions and structures for the files.

More information about the following file formats is provided in this documentation:

| Item                    | Description                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| acct                    | Describes the format of the records in the system accounting files.                                                          |
| ar                      | Describes the format of an archive file.                                                                                     |
| audit                   | Describes values used by the auditing system as well as the structure of a bin.                                              |
| bootptab                | Describes the default configuration database for the Internet Boot Protocol server ( <b>bootpd</b> ).                        |
| CGM                     | Defines a file format for storage and retrieval of device-independent graphics.                                              |
| charmap                 | Defines character symbols as character encodings.                                                                            |
| core                    | Describes the structures created in a <b>core</b> file as a result of a core dump.                                           |
| cpio                    | Describes the cpio (copy in/out) archive file.                                                                               |
| eqnchar                 | Contains special character definitions for the <b>eqn</b> and <b>neqn</b> commands.                                          |
| lastlog                 | Defines the last login attributes for users.                                                                                 |
| ldapattribmap           | Defines AIX® to LDAP attribute name mapping to support configurable LDAP server schema.                                      |
| locale definition       | Contains one or more categories that describe a locale.                                                                      |
| locale method           | Specifies the methods to be overridden when constructing a locale.                                                           |
| magic                   | Defines file types.                                                                                                          |
| mailrc                  | Sets defaults for the <b>mail</b> command.                                                                                   |
| mh_alias                | Defines aliases for the Message Handler (MH).                                                                                |
| mib_defs                | Provides descriptions of Management Information Base (MIB) variables for the <b>snmpinfo</b> command.                        |
| nroff and troff         | Specifies input file format for the nroff and troff commands.                                                                |
| input                   |                                                                                                                              |
| nterm                   | Describes the format of the terminal driver tables for the nroff command.                                                    |
| profile                 | Describes the format of the profile and .profile files, which set the user environment at login time.                        |
| queuedefs               | Describes the format of the file used by the cron daemon to handle event types.                                              |
| sccsfile                | Describes the format of a Source Code Control System (SCCS) file.                                                            |
| setmaps                 | Defines the text of a code-set map file and a terminal map file.                                                             |
| terminfo                | Contains compiled <b>terminfo</b> source files.                                                                              |
| TIFF                    | Enables InfoCrafter to support scanned images that have been imported into Interleaf documents.                              |
| trcfmt                  | Stores trace templates.                                                                                                      |
| troff                   | Describes the output language of the <b>troff</b> command.                                                                   |
| troff Font              | Describes the format of the <b>troff</b> command font files.                                                                 |
| tunables                | Centralizes tunable parameter values.                                                                                        |
| UIL                     | Contains information on the user interface for a widget-based application.                                                   |
| utmp, wtmp, failedlogin | Describes the format of the user and accounting information in the <b>utmp</b> , <b>wtmp</b> , and <b>failedlogin</b> files. |
| vgrindef                | Contains the language definition database for the <b>vgrind</b> command.                                                     |
| WML                     | Generates variable UIL compiler components.                                                                                  |

## Asynchronous Terminal Emulation (ATE) File Formats

| Item                               | Description                                                                         |
|------------------------------------|-------------------------------------------------------------------------------------|
| <code>ate.def</code>               | Determines default settings for use in asynchronous connections and file transfers. |
| <code>ATE Dialing Directory</code> | Lists phone numbers that the ATE program uses to establish modem connections.       |

## Basic Networking Utilities (BNU) File Formats

| Item                     | Description                                                                                                                                                     |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>Devices</code>     | Contains information about devices on the local system that can establish a connection to a remote computer using the Basic Networking Utilities (BNU) program. |
| <code>Dialcodes</code>   | Contains the initial digits of telephone numbers used to establish remote connections over a phone line.                                                        |
| <code>Dialers</code>     | Lists modems used for Basic Networking Utilities (BNU) remote communications links.                                                                             |
| <code>Maxuuscheds</code> | Limits the number of instances of the <code>uusched</code> and <code>ucico</code> daemons that can run simultaneously.                                          |
| <code>Maxuuxqts</code>   | Limits the number of instances of the BNU <code>uuxqt</code> daemon that can run simultaneously on the local system.                                            |
| <code>Permissions</code> | Specifies BNU permissions for remote systems that call or are called by the local system.                                                                       |
| <code>Poll</code>        | Specifies when the BNU program should poll remote systems.                                                                                                      |
| <code>Systems</code>     | Lists remote computers with which users of the local system can communicate using the Basic Networking Utilities (BNU) program.                                 |

## tip File Formats

| Item                | Description                                                                           |
|---------------------|---------------------------------------------------------------------------------------|
| <code>phones</code> | Describes connections used by the <code>tip</code> command to contact remote systems. |
| <code>remote</code> | Describes remote systems contacted by the <code>tip</code> command.                   |
| <code>.tiprc</code> | Provides initial settings of variables for the <code>tip</code> command.              |

## TCP/IP System Management File Formats

| Item                             | Description                                                                                                                  |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <code>3270keys</code>            | Defines user keyboard mapping and colors for TELNET (3270).                                                                  |
| <code>Domain Cache</code>        | Defines the root name server or servers for a DOMAIN name server host.                                                       |
| <code>Domain Data</code>         | Stores name resolution information for the <code>named</code> daemon.                                                        |
| <code>Domain Local Data</code>   | Defines the local loopback information for <code>named</code> on the name server host.                                       |
| <code>Domain Reverse Data</code> | Stores reverse name resolution information for the <code>named</code> daemon.                                                |
| <code>/etc/ftpd.cnf</code>       | Specifies configuration parameters of the <code>ftpd</code> daemon to start a TLS session.                                   |
| <code>.ftpcnf</code>             | Specifies configuration parameters of the <code>ftp</code> command to start a TLS session.                                   |
| <code>ftputers</code>            | Specifies local user names that cannot be used by remote FTP clients.                                                        |
| <code>gated.conf</code>          | Contains configuration information for the <code>gated</code> daemon.                                                        |
| <code>gateways</code>            | Specifies Internet routing information to the <code>routed</code> and <code>gated</code> daemons on a network.               |
| <code>hosts</code>               | Defines the Internet Protocol (IP) name and address of the local host and specifies the names and addresses of remote hosts. |
| <code>hosts.equiv</code>         | Specifies remote systems that can execute commands on the local system.                                                      |
| <code>hosts.lpd</code>           | Specifies remote hosts that can print on the local host.                                                                     |
| <code>inetd.conf</code>          | Defines how the <code>inetd</code> daemon handles Internet service requests.                                                 |
| <code>map3270</code>             | Defines keyboard mapping and colors for the <code>tn3270</code> command.                                                     |
| <code>netcd.conf</code>          | Defines parameters for the <code>netcd</code> daemon.                                                                        |
| <code>.netrc</code>              | Specifies automatic login information for the <code>ftp</code> and <code>rexec</code> commands.                              |
| <code>networks</code>            | Contains the network name file.                                                                                              |
| <code>protocols</code>           | Defines the Internet protocols used on the local host.                                                                       |
| <code>rc.net</code>              | Defines host configuration for the following areas: network interfaces, host name, default gateway, and any static routes.   |
| <code>resolv.conf</code>         | Defines DOMAIN name server information for local resolver routines.                                                          |
| <code>rfc1108</code>             | Contains the mapping between AIX® Trusted Network labels and rfc1108 labels.                                                 |
| <code>.rhosts</code>             | Specifies remote users that can use a local user account on a network.                                                       |
| <code>services</code>            | Defines the sockets and protocols used for Internet services.                                                                |

| Item                                   | Description                                                                                                               |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Standard Resource Record Format</b> | Defines the format of lines in the DOMAIN data files.                                                                     |
| <b>telnet.conf</b>                     | Translates a client's terminal-type strings into <b>terminfo</b> file entries.                                            |
| <b>cgaparams.sec</b>                   | Defines the color graphics adapter (CGA) parameter keywords for the <b>ndpd-host</b> daemon and <b>autoconf6</b> command. |
| <b>ndpdh.cnf</b>                       | Defines the configuration file locations for the <b>ndpd-host</b> daemon and the <b>autoconf6</b> command.                |
| <b>sendh_anchor</b>                    | Defines the trusted anchor for the <b>ndpd-host</b> daemon.                                                               |
| <b>sendr_anchor</b>                    | Defines the trusted anchors for the <b>ndpd-router</b> daemon.                                                            |
| <b>tempaddr.conf</b>                   | Defines if temporary addresses should be allowed or denied                                                                |

## .3270keys File Format for TCP/IP

### Purpose

Defines keyboard mapping and colors for the **tn** and **telnet** command.

### Description

The **\$HOME/.3270keys** file specifies for a user a **tn** or **telnet** command key mapping that differs from the default mapping found in the **/etc/3270.keys** file. You can use it, for example, to make the Action key act as the Enter key.

If you are using a color display, you can also customize the colors for various 3270 display attributes by setting attributes in the **.3270keys** file. The default mapping in the **/etc/3270.keys** file is generic. The user can also load the user-defined files for specific terminal types by using the **.3270keys** file. The **.3270keys** file is specified in the user's home directory. The default background color is black. You cannot configure the background color.

The **tn** or **telnet** command first checks the **\$HOME** directory for the **.3270keys** file and loads it. If the file doesn't exist, the **/etc/3270.keys** file is loaded. Both files, by default, end with an **if** statement and a list of terminal types. If the **TERM** environment variable matches one of the listed terminals, a second file is loaded. If the **TERM** variable does not match, the **tn** or **telnet** command uses the generic key bindings specified before the **if** statement and prints the message **NOBINDINGS**. This file is part of TCP/IP in Network Support Facilities.

**Note:** When remapping keys to customize your **\$HOME/.3270keys** file, remember that you cannot map a 3270 function to the Esc key alone. You can specify the Esc key only in combination with another key. Also, when mapping keys, do not duplicate key sequences. For example, if you have mapped the backtab function to the **^A** (the Ctrl-A key sequence), then mapping the PF1 function key to **^Aep** (the Ctrl-Aep key sequence) is going to conflict with the backtab mapping.

### The **\$HOME/.3270keys.hft** File

You can also use the **/usr/lpp/tcpip/samples/3270keys.hft** sample file to create a **\$HOME/.3270keys.hft** file by copying the sample file to your home directory and modifying it as necessary.

The following options can be used in the sequence field:

| Item | Description                                     |
|------|-------------------------------------------------|
| \b   | Backspace                                       |
| \s   | Space                                           |
| \t   | Tab                                             |
| \n   | New line                                        |
| \r   | Return                                          |
| \e   | Escape                                          |
| ^    | Mask next character with \037; for example, ^M. |
| ~    | Set high-order bit for next character.          |

The following are valid colors for 3270 display attributes:

- black
- blue
- red
- green
- white
- magenta
- cyan

For more information about changing the assignment of a key set, see [Changing the assignment of a key set in Networks and communication management](#).

**Note:** The **3270keys.hft** file supports the Attention key, which sends an IAC BREAK TELNET protocol sequence to the TELNET server on a VM or MVS™ system. The TELNET server is responsible for implementing the Attention key. Example 2 shows the format for binding the Attention key to the Ctrl-F12 key sequence.

## Examples

1. The following example binds the Backspace key and the Tab keys:

```
3270 Function Sequence Key
bind backspace "\b" #backspace key
bind tab "\t" #tab key
```

The # (pound sign) is used to indicate comments.

2. The following example binds the Attention key to the Ctrl-F12 key sequence:

```
3270 Function Sequence Key
bind attention "\e[036q" #attention key
```

## Files

| Item                                | Description                                                  |
|-------------------------------------|--------------------------------------------------------------|
| /etc/3270.keys                      | Contains the default keyboard mapping for non-HFT keyboards. |
| /etc/3270keys.hft                   | Contains the default keyboard mapping for HFT keyboards.     |
| /usr/lpp/tcpip/samples/3270keys.hft | Contains a sample HFT keyboard mapping.                      |

## acct File Format

### Purpose

Provides the accounting file format for each process.

### Description

The accounting files provide a means to monitor the use of the system. These files also serve as a method for billing each process for processor usage, materials, and services. The **acct** system call produces accounting files. The **/usr/include/sys/acct.h** file defines the records in these files, which are written when a process exits.

#### The acct structure

The **acct** structure in the **acct.h** header file contains the following fields:

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ac_flag   | Specifies one of the following accounting flags for the process for which the accounting record is written:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| AFORK     | The process was created using a <b>fork</b> command but an <b>exec</b> subroutine has not yet followed. The <b>exec</b> subroutine turns off the AFORK flag.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ASU       | The process used root user authority.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ac_stat   | Specifies the exit status. A flag that indicates how the process terminated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ac_uid    | Specifies the user ID of the process for which the accounting record is written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ac_gid    | Specifies the group ID of the process for which the accounting record is written.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ac_tty    | Specifies the terminal from which the process was started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| ac_wlmkey | Holds a 64-bit numeric key representing the Workload Manager class to which the process belonged. The Workload Manager Application Programming Interface provides the <b>wlm_key2class</b> subroutine to convert the key back to a class name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ac_btime  | Specifies the beginning time. The time at which the process started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ac_utime  | Specifies the amount of user time, in seconds, used by the process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ac_stime  | Specifies the amount of system time, in seconds, used by the process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ac_etime  | Specifies the amount of time, in seconds, elapsed since the command ran.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| ac_mem    | Specifies the average amount of memory used by the process. Every clock interrupt (or clock tick, 100 times per second), the <b>sys_timer</b> routine is called to update the user data for the current process. If the process is in user mode, both its <b>u_utime</b> value and memory usage values are incremented; otherwise, only its <b>u_stime</b> value is incremented. The <b>sys_timer</b> routine calls the <b>vms_rusage</b> routine to obtain the kilobytes of real memory being used by TEXTSEG (#1), the PRIVSEG (#2), and the big-data segments (#3-11), if used. These values are added to the total memory usage value at each clock tick during which the process is not in kernel mode. When the process ends, the <b>acctexit</b> routine computes how many clock ticks occurred while the process executed (in both user and kernel modes) and divides the total memory usage value by this number to give an average memory usage for the process. This value is recorded as a two-byte unsigned short integer. |
| ac_io     | Specifies the number of characters transferred by the process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ac_rw     | Specifies the number of blocks read or written by the process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ac_comm   | Specifies the name of the command that started the process. A child process created by a <b>fork</b> subroutine receives this information from the parent process. An <b>exec</b> subroutine resets this field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

#### The tacct Structure

The **tacct** structure, which is not part of the **acct.h** header file, represents the total accounting format used by the various accounting commands:

```
struct tacct {
 uid_t ta_uid; /* user-ID */
 char ta_name[8]; /* login name */
 float ta_cpu[2]; /* cum. CPU time, p/np (mins) */
 float ta_kcore[2]; /* cum. kcore-mins, p/np */
 float ta_io[2]; /* cum. chars xferred (512s) */
 float ta_rw[2]; /* cum. blocks read/written */
 float ta_con[2]; /* cum. connect time, p/np, mins */
 float ta_du; /* cum. disk usage */
 long ta_qsys; /* queuing sys charges (pgs) */
```

```

 float ta_fee; /* fee for special services */
 long ta_pc; /* count of processes */
 unsigned short ta_sc; /* count of login sessions */
 unsigned short ta_dc; /* count of disk samples */
};

```

## **ar File Format (Big)**

### **Purpose**

Combines several files into one. This is the default **ar** library archive format for the operating system.

### **Description**

The **ar** (archive) file format combines several files into one. The **ar** command creates an archive file. The **ld** (link editor) command searches archive files to resolve program linkage. The **/usr/include/ar.h** file describes the archive file format. This file format accommodates both 32-bit and 64-bit object files within the same archive.

This is the default file format used by the **ar** command.

#### **Fixed-Length Header**

Each archive begins with a fixed-length header that contains offsets to special archive file members. The fixed-length header also contains the magic number, which identifies the archive file. The fixed-length header has the following format:

```

#define __AR_BIG__
#define AIAMAGBIG "<bigaf>\n" /* Magic string */
#define SAIAMAG 8 /*Length of magic string */
struct fl_hdr /*Fixed-length header */

{
char fl_magic[SAIAMAG]; /* Archive magic string */
char fl_memoff[20]; /*Offset to member table */
char fl_gstoff[20]; /*Offset to global symbol table */
char fl_gst64off[20]; /*Offset global symbol table for 64-bit objects */
char fl_fstmoff[20]; /*Offset to first archive member */
char fl_lstmoff[20]; /*Offset to last archive member */
char fl_freeoff[20]; /*Offset to first mem on free list */
}
;

```

The indexed archive file format uses a double-linked list within the archive file to order the file members. Therefore, file members may not be sequentially ordered within the archive. The offsets contained in the fixed-length header locate the first and last file members of the archive. Member order is determined by the linked list.

The fixed-length header also contains the offsets to the member table, the global symbol table, and the free list. Both the member table and the global symbol table exist as members of the archive and are kept at the end of the archive file. The free list contains file members that have been deleted from the archive.

When adding new file members to the archive, free list space is used before the archive file size is expanded. A zero offset in the fixed-length header indicates that the member is not present in the archive file.

## File Member Header

Each archive file member is preceded by a file member header, which contains the following information about the file member:

```
#define AIAFMAG "^\n" /* Header trailer string*/
struct ar_hdr /* File member header*/
{
 char ar_size[20]; /* File member size - decimal */
 char ar_nxtmem[20]; /* Next member offset-decimal */
 char ar_prvmem[20]; /* Previous member offset-dec */
 char ar_date[12]; /* File member date-decimal */
 char ar_uid[12]; /* File member userid-decimal */
 char ar_gid[12]; /* File member group id-decimal */
 char ar_mode[12]; /* File member mode-octal */
 char ar_namlen[4]; /* File member name length-dec */

 union
 {
 char ar_name[2]; /* Start of member name */
 char ar_fmag[2]; /* AIAFMAG - string to end */
 };
 _ar_name; /* Header and member name */
};
```

The member header provides support for member names up to 255 characters long. The `ar_namlen` field contains the length of the member name. The character string containing the member name begins at the `_ar_name` field. The AIAFMAG string is cosmetic only.

Each archive member header begins on an even-byte boundary. The total length of a member header is:  
`sizeof (struct ar_hdr) + ar_namlen`

The actual data for a file member begins at the first even-byte boundary beyond the member header and continues for the number of bytes specified by the `ar_size` field. The `ar` command inserts null bytes for padding where necessary.

All information in the fixed-length header and archive members is in printable ASCII format. Numeric information, with the exception of the `ar_mode` field, is stored as decimal numbers; the `ar_mode` field is stored in octal format. Thus, if the archive file contains only printable files, you can print the archive.

## Member Table

A member table is always present in an indexed archive file. This table quickly locates members of the archive. The `fl_memoff` field in the fixed-length header contains the offset to the member table. The member table member has a zero-length name. The `ar` command automatically creates and updates (but does not list) the member table. A member table contains the following information:

- The number of members. This member is 20 bytes long and stored in ASCII format as a decimal number.
- The array of offsets into the archive file. The length is 20 times the number of members. Each offset is 20 bytes long and stored in ASCII format as a decimal number.
- The name string table. The size is:

```
ar_size - (20 * (the number of members +1));
```

that is, the size equals the total length of all members minus the length of the offsets, minus the length of the number of members.

The string table contains the same number of strings as offsets. All strings are null-terminated. Each offset from the array corresponds sequentially to a name in the string table.

## Global Symbol Tables

Immediately following the member table, the archive file contains two global symbol tables. The first global symbol table locates 32-bit file members that define global symbols; the second global symbol table does the same for 64-bit file members. If the archive has no 32-bit or 64-bit file members, the respective global symbol table is omitted. The **strip** command can be used to delete one or both global symbol tables from the archive. The **f1\_gstoff** field in the fixed-length header contains the offset to the 32-bit global symbol table, and the **f1\_gst64off** contains the offset to the 64-bit global symbol table. The global symbol table members have zero-length names. The **ar** command automatically creates and updates, but does not list the global symbol tables. A global symbol table contains the following information:

- The number of symbols. This is 8 bytes long and can be accessed with the **sgetl** and **sputl** commands.
- The array of offsets into the archive file. The length is eight times the number of symbols. Each offset is 8 bytes long and can be accessed with the **sgetl** and **sputl** commands.
- The name-string table. The size is:

```
ar_size - (8 * (the number of symbols + 1));
```

That is, the size equals the total length of the members, minus the length of the offsets, minus the length of the number of symbols.

The string table contains the same number of strings as offsets. All strings are null-terminated. Each offset from the array corresponds sequentially to a name in the string table.

## ar File Format (Small)

### Purpose

Describes the small indexed archive file format, in use prior to Version 4.3 of the operating system. This format is recognized by commands for backward compatibility purposes only. See **ar File Format (Big)** for the current archive file format.

### Description

The **ar** (archive) command combines several files into one. The **ar** command creates an archive file. The **ld** (link editor) command searches archive files to resolve program linkage. The **/usr/include/ar.h** file describes the archive file format. This archive format only handles 32-bit XCOFF members. The **ar File Format (Big)** handles both 32-bit and 64-bit XCOFF members

### Fixed-Length Header

Each archive begins with a fixed-length header that contains offsets to special archive file members. The fixed-length header also contains the magic number, which identifies the archive file. The fixed-length header has the following format:

```
#define AIAMAG "<aiaff>\n" /* Magic string */

#define SAIAMAG 8 /* Length of magic string */

struct f1_hdr /* Fixed-length header */
```

```

{
char fl_magic[SAIAMAG]; /* Archive magic string */
char fl_memoff[12]; /* Offset to member table */
char fl_gstoff[12]; /* Offset to global symbol table */
char fl_fstmoff[12]; /* Offset to first archive member */
char fl_lstmoff[12]; /* Offset to last archive member */
char fl_freeoff[12]; /* Offset to first mem on free list */

};

```

The indexed archive file format uses a double-linked list within the archive file to order the file members. Therefore, file members may not be sequentially ordered within the archive. The offsets contained in the fixed-length header locate the first and last file members of the archive. Member order is determined by the linked list.

The fixed-length header also contains the offsets to the member table, the global symbol table, and the free list. Both the member table and the global symbol table exist as members of the archive and are kept at the end of the archive file. The free list contains file members that have been deleted from the archive. When adding new file members to the archive, free list space is used before the archive file size is expanded. A zero offset in the fixed-length header indicates that the member is not present in the archive file.

## File Member Header

Each archive file member is preceded by a file member header, which contains the following information about the file member:

```

#define AIAFMAG "~\n" /* Header trailer string */
struct ar_hdr /* File member header */
{
 char ar_size[12]; /* File member size - decimal */
 char ar_nxtmem[12]; /* Next member offset - decimal */
 char ar_prvmem[12]; /* Previous member offset - dec */
 char ar_date[12]; /* File member date - decimal */
 char ar_uid[12]; /* File member user id - decimal */
 char ar_gid[12]; /* File member group id - decimal */
 char ar_mode[12]; /* File member mode - octal */
 char ar_namlen[4]; /* File member name length - dec */
 union
 {
 char ar_name[2]; /* Start of member name */
 char ar_fmag[2]; /* AIAFMAG - string to end */
 };
 _ar_name; /* Header and member name */
};

```

The member header provides support for member names up to 255 characters long. The `ar_namlen` field contains the length of the member name. The character string containing the member name begins at the `_ar_name` field. The AIAFMAG string is cosmetic only.

Each archive member header begins on an even-byte boundary. The total length of a member header is:  
`sizeof (struct ar_hdr) + ar_namlen`

The actual data for a file member begins at the first even-byte boundary beyond the member header and continues for the number of bytes specified by the `ar_size` field. The `ar` command inserts null bytes for padding where necessary.

All information in the fixed-length header and archive members is in printable ASCII format. Numeric information, with the exception of the `ar_mode` field, is stored as decimal numbers; the `ar_mode` field is stored in octal format. Thus, if the archive file contains only printable files, you can print the archive.

## **Member Table**

A member table is always present in an indexed archive file. This table quickly locates members of the archive. The `f1_memooff` field in the fixed-length header contains the offset to the member table. The member table member has a zero-length name. The `ar` command automatically creates and updates (but does not list) the member table. A member table contains the following information:

- The number of members. This member is 12 bytes long and stored in ASCII format as a decimal number.
- The array of offsets into the archive file. The length is 12 times the number of members. Each offset is 12 bytes long and stored in ASCII format as a decimal number.
- The name string table. The size is:

```
ar_size - (12 * (the number of members +1));
```

that is, the size equals the total length of all members minus the length of the offsets, minus the length of the number of members.

The string table contains the same number of strings as offsets. All strings are null-terminated. Each offset from the array corresponds sequentially to a name in the string table.

## **Global Symbol Table**

If an archive file contains XCOFF object-file members that are not stripped, the archive file will contain a global symbol-table member. This global symbol table locates file members that define global symbols. The `strip` command deletes the global symbol table from the archive. The `f1_gstoff` field in the fixed-length header contains the offset to the global symbol table. The global symbol table member has a zero-length name. The `ar` command automatically creates and updates, but does not list the global symbol table. A global symbol table contains the following information:

- The number of symbols. This is 4 bytes long and can be accessed with the `sgetl` and `sputl` commands.
- The array of offsets into the archive file. The length is four times the number of symbols. Each offset is 4 bytes long and can be accessed with the `sgetl` and `sputl` commands.
- The name-string table. The size is:

```
ar_size - (4 * (the number of symbols + 1));
```

That is, the size equals the total length of the members, minus the length of the offsets, minus the length of the number of symbols.

The string table contains the same number of strings as offsets. All strings are null-terminated. Each offset from the array corresponds sequentially to a name in the string table.

## **ate.def File Format**

### **Purpose**

Determines default settings for the Asynchronous Terminal Emulation (ATE) program.

## Description

The **ate.def** file sets the defaults for use in asynchronous connections and file transfers. This file is part of Asynchronous Terminal Emulation and is created in the current directory during the first run of ATE. The **ate.def** file contains the default values in the ATE program uses for the following:

- Data transmission characteristics
- Local system features
- Dialing directory file
- Control keys

The first time the ATE program runs from a particular directory, it creates the **ate.def** file in that directory, with settings as follows:

| Item         | Description  |
|--------------|--------------|
| LENGTH       | 8            |
| STOP         | 1            |
| PARITY       | 0            |
| RATE         | 1200         |
| DEVICE       | tty0         |
| INITIAL      | ATDT         |
| FINAL        |              |
| WAIT         | 0            |
| ATTEMPTS     | 0            |
| TRANSFER     | p            |
| CHARACTER    | 0            |
| NAME         | kapture      |
| LINEFEEDS    | 0            |
| ECHO         | 0            |
| VT100        | 0            |
| WRITE        | 0            |
| XON/XOFF     | 1            |
| DIRECTORY    | /usr/lib/dir |
| CAPTURE_KEY  | 002          |
| MAINMENU_KEY | 026          |
| PREVIOUS_KEY | 022          |

Edit the **ate.def** file with any ASCII text editor to permanently change the values of these characteristics. Temporarily change the values of these characteristics with the ATE **alter** and **modify** subcommands, accessible from either ATE Main Menu.

### Parameters in the ate.def File

Type parameter names in uppercase letters in the **ate.def** file. Spell the parameters exactly as they appear in the original default file. Define only one parameter per line. An incorrectly defined value for a parameter causes ATE to return a system message. However, the program continues to run using the default value.

These are the **ate.def** file parameters:

| <b>Item</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                  |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LENGTH      | Specifies the number of bits in a data character. This length must match the length expected by the remote system.<br><br>Options: 7 or 8.                                                                                                                                                                                                                          |
| STOP        | Default: 8.<br>Specifies the number of stop bits appended to a character to signal that character's end during data transmission. This number must match the number of stop bits used by the remote system.<br><br>Options: 1 or 2.                                                                                                                                 |
| PARITY      | Default: 1.<br>Checks whether a character is successfully transmitted to or from a remote system. Must match the parity of the remote system.<br><br>For example, if the user selects even parity, when the number of 1 bits in the character is odd, the parity bit is turned on to make an even number of 1 bits.<br><br>Options: 0 (none), 1 (odd), or 2 (even). |
| RATE        | Default: 0.<br>Determines the baud rate, or the number of bits transmitted per second (bps). The speed must match the speed of the modem and that of the remote system.<br><br>Options: 50, 75, 110, 134, 150, 300, 600, 1200, 1800, 2400, 4800, 9600, or 19,200.                                                                                                   |
| DEVICE      | Default: 1200.<br>Specifies the name of the asynchronous port used to make a connection to a remote system.<br><br>Options: Locally created port names.                                                                                                                                                                                                             |
| INITIAL     | Default: tty0.<br>Defines the dial prefix, a string that must precede the telephone number when the user autodials with a modem. For the proper dial commands, consult the modem documentation.<br><br>Options: ATDT, ATDP, or other values, depending on the type of modem.                                                                                        |
| FINAL       | Default: ATDT.<br>Defines the dial suffix, a string that must follow the telephone number when the user autodials with a modem. For the proper dial commands, consult the modem documentation.<br><br>Options: Blank (none) or a valid modem suffix.                                                                                                                |
| WAIT        | Default: No default.<br>Specifies the time to wait between redialing attempts. The wait period does not begin until the connection attempt times out or until it is interrupted. If the ATTEMPTS parameter is set to 0, no redial attempt occurs.<br><br>Options: 0 (none) or a positive integer designating the number of seconds to wait.                         |
| ATTEMPTS    | Default: 0.<br>Specifies the maximum number of times the ATE program tries to redial to make a connection. If the ATTEMPTS parameter is set to 0, no redial attempt occurs.<br><br>Options: 0 (none) or a positive integer designating the number of attempts.                                                                                                      |

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TRANSFER  | Defines the type of asynchronous protocol that transfers files during a connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|           | <p><b>p      pacing:</b></p> <p>File transfer protocol controls the data transmission rate by waiting for a specified character or for a certain number of seconds between line transmissions. This helps prevent loss of data when the transmission blocks are either too large or sent too quickly for the system to process.</p> <p><b>x      xmodem:</b></p> <p>An 8-bit file transfer protocol to detect data transmission errors and retransmit the data.</p> <p>Options: <b>p (pacing)</b>, <b>x (xmodem)</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                             |
| CHARACTER | <p>Default: <b>p</b>.</p> <p>Specifies the type of <b>pacing</b> protocol to be used.</p> <p><i>Character</i></p> <p>Signal to transmit a line. Select one character.</p> <p>When the <b>send</b> subcommand encounters a line-feed character while transmitting data, the subcommand waits to receive the pacing character before sending the next line.</p> <p>When the <b>receive</b> subcommand is ready to receive data, it sends the pacing character, then waits 30 seconds to receive data. The <b>receive</b> subcommand sends a pacing character again whenever it finds a carriage-return character in the data. The <b>receive</b> subcommand ends when it receives no data for 30 seconds.</p> <p><i>Interval</i>   Number of seconds the system waits between each line it transmits. The value of the <i>Interval</i> variable must be an integer. The default value is 0, indicating a pacing delay of 0 seconds.</p> |
| NAME      | <p>Default: 0.</p> <p>File name for incoming data (capture file).</p> <p>Options: A valid file name less than 40 characters long.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| LINEFEEDS | <p>Default: The <b>kapture</b> file.</p> <p>Adds a line-feed character after every carriage-return character in the incoming data stream.</p> <p>Options: 1 (on) or 0 (off).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ECHO      | <p>Default: 0.</p> <p>Displays the user's typed input.</p> <p>For a remote computer that supports echoing, each character sent returns and displays on the screen. When the ECHO parameter is on, each character is displayed twice: first when it is entered, and again when it returns over a connection. When the ECHO parameter is off, each character displays only when it returns over the connection.</p> <p>Options: 1 (on) or 0 (off).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| VT100     | <p>Default: 0.</p> <p>The local console emulates a DEC VT100 terminal so DEC VT100 codes can be used with the remote system. With the VT100 parameter off, the local console functions like a workstation.</p> <p>Options: 1 (on) or 0 (off).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| WRITE     | <p>Default: 0.</p> <p>Captures incoming data and routes it to the file specified in the NAME parameter as well as to the display. Carriage-return or line-feed combinations are converted to line-feed characters before they are written to the capture file. In an existing file, data is appended to the end of the file.</p> <p><b>Note:</b> The CAPTURE_KEY (usually the Ctrl-B key sequence) can be used to toggle capture mode on or off during a connection.</p> <p>Options: 1 (on) or 0 (off).</p> <p>Default: 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Item</b>  | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| XON/XOFF     | <p>Controls data transmission at a port as follows:</p> <ul style="list-style-type: none"> <li>• When an <b>Xoff</b> signal is received, transmission stops.</li> <li>• When an <b>Xon</b> signal is received, transmission resumes.</li> <li>• An <b>Xoff</b> signal is sent when the receive buffer is nearly full.</li> <li>• An <b>Xon</b> signal is sent when the buffer is no longer full.</li> </ul> <p>Options: 1 (On) or 0 (Off).</p> |
| DIRECTORY    | <p>Default: 1.</p> <p>Names the file that contains the user's dialing directory.</p>                                                                                                                                                                                                                                                                                                                                                           |
| CAPTURE_KEY  | <p>Default: the <b>/usr/lib/dir</b> file.</p> <p>Defines the control key sequence that toggles capture mode. When pressed, the CAPTURE_KEY (usually the Ctrl-B key sequence) starts or stops capturing (saving) the data that is displayed on the screen during an active connection.</p> <p>Options: Any ASCII control character.</p>                                                                                                         |
| MAINMENU_KEY | <p>Default: ASCII octal 002 (STX).</p> <p>Defines the control key sequence that returns the ATE Connected Main Menu so the user can issue a command during an active connection. The MAINMENU_KEY (usually the Ctrl-V key sequence) functions only from the connected state.</p> <p>Options: Any ASCII control character.</p>                                                                                                                  |
| PREVIOUS_KEY | <p>Default: ASCII octal 026 (SYN).</p> <p>Defines the control key sequence that displays the previous screen anytime during the program. The screen displayed varies, depending on the screen in use when the user presses PREVIOUS_KEY (usually the Ctrl-R key sequence).</p> <p>Options: Any ASCII control character.</p> <p>Default: ASCII octal 022 (DC2). The ASCII control character is mapped to the interrupt signal.</p>              |

#### Note:

1. Changing or remapping may be necessary if control keys conflict across applications. For example, if the control keys mapped for the ATE program conflict with those in a text editor, remap the ATE control keys.
2. The ASCII control character selected may be in octal, decimal, or hexadecimal format, as follows:

| <b>Item</b> | <b>Description</b>                                                                  |
|-------------|-------------------------------------------------------------------------------------|
| octal       | 000 through 037. The leading zero is required.                                      |
| decimal     | 0 through 31.                                                                       |
| hexadecimal | 0x00 through 0x1F. The leading 0x is required. The x may be uppercase or lowercase. |

## Examples

To change characteristics of ATE emulation, create an **ate.def** file that defines those characteristics.

For example, to change the RATE to 300 bps, the DEVICE to tty3, the TRANSFER mode to x (**xmodem** protocol), and the DIRECTORY to my.dir, create the following **ate.def** file in the directory running the ATE program:

```
RATE 300
DEVICE tty3
TRANSFER x
DIRECTORY my.dir
```

The time the ATE program starts from that directory, the program uses the defined values.

## Files

| Item         | Description                                  |
|--------------|----------------------------------------------|
| /usr/lib/dir | Contains the default dialing directory file. |

## audit File Format

### Purpose

Describes the auditing data structures.

### Description

The */usr/include/sys/audit.h* file contains structure and constant definitions for the auditing system commands, subroutines, and daemons:

#### Audit Bin Format

The format of the audit bin is described by the **aud\_bin** structure. An audit trail consists of a sequence of bins, each of which must start with a bin head and end with a bin tail. The **aud\_bin** structure contains the following fields:

| Item          | Description                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bin_magic     | The magic number for the bin (0xf0f0).                                                                                                                                   |
| bin_version   | The version number for the bin (0).                                                                                                                                      |
| bin_tail      | Indicates whether the bin describes the audit trail head or tail:<br><br>0 Identifies the bin header.<br>1 Identifies the bin end (tail).<br>2 Identifies the trail end. |
| bin_len       | The (unpacked) length of the bin's records. A nonzero value indicates that the bin has a tail record.                                                                    |
| bin_plen      | The current length of the bin's record (might be packed).                                                                                                                |
| bin_time      | The time at which the head or tail was written.                                                                                                                          |
| bin_reserved1 | Not currently used.                                                                                                                                                      |
| bin_reserved2 | Not currently used.                                                                                                                                                      |

#### Audit Class Format

The format of the audit class is described by the **audit\_class** structure, which contains the following fields:

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ae_name | A pointer to the name of the audit class.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| ae_list | A pointer to a list of null-terminated audit event names for this audit class. The list is ended by a null name (a leading null byte or two consecutive null bytes).                                                                                                                                                                                                                                                                                                 |
| ae_len  | <p><b>Note:</b> Event and class names are limited to 15 significant characters.</p> <p>The length of the event list in the ae_list member. This length includes the terminating null bytes. On an AUDIT_SET operation, the caller must set this member to indicate the actual length of the list (in bytes) pointed to by ae_list. On an AUDIT_GET or AUDIT_LOCK operation, the auditevents subroutine sets this member to indicate the actual size of the list.</p> |

## Audit Object Format

The format of the audit object is described by the **o\_event** structure, which contains the following fields:

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| o_type  | Specifies the type of the object, in terms of naming space. Currently, only one object-naming space is supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         | <b>AUDIT_FILE</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         | Denotes the file system naming space.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| o_name  | Specifies the name of the object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| o_event | <p>Specifies any array of event names to be generated when the object is accessed. Note that event names are currently limited to 16 bytes, including the trailing null. The index of an event name in this array corresponds to an access mode. Valid indexes are defined in the <b>audit.h</b> file and include the following:</p> <ul style="list-style-type: none"> <li>• <b>AUDIT_READ</b></li> <li>• <b>AUDIT_WRITE</b></li> <li>• <b>AUDIT_EXEC</b></li> </ul> <p><b>Note:</b> The C++ compiler will generate a warning indicating that <b>o_event</b> is defined both as a structure and a field within that structure. Although the <b>o_event</b> field can be used within C++, the warning can be bypassed by defining <b>O_EVENT_RENAME</b>. This will replace the <b>o_event</b> field with <b>o_event_array</b>. <b>o_event</b> is the default field.</p> |

## Audit Record Format

Each audit record consists of a list of fixed-length event identifiers, each of which can be followed by a variable-length tail. The format of the audit record is described by the **aud\_rec** structure, which contains the following fields to identify the event:

| Item         | Description                                                                                         |
|--------------|-----------------------------------------------------------------------------------------------------|
| ah_magic     | Magic number for audit record.                                                                      |
| ah_length    | The length of the tail portion of the audit record.                                                 |
| ah_event[16] | The name of the event and a null terminator.                                                        |
| ah_result    | An indication of whether the event describes a successful operation. The values for this field are: |
|              | 0      Indicates successful completion.                                                             |
|              | 1      Indicates a failure.                                                                         |
|              | >1     An <b>errno</b> value describing the failure.                                                |

The **aud\_rec** structure also contains the following fields to identify the user and the process:

| Item        | Description                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------|
| ah_ruid     | The real user ID; that is, the ID number of the user who created the process that wrote this record. |
| ah_luid     | The login ID of the user who created the process that wrote this record.                             |
| ah_name[16] | The program name of the process, along with a null terminator.                                       |
| ah_pid      | The process ID of the process that wrote this record.                                                |
| ah_ppid     | The process ID of the parent of this process.                                                        |
| ah_time     | The time in seconds at which this audit record was written.                                          |
| ah_ntime    | The nanoseconds offset from ah_time.                                                                 |

The record tail follows this header information.

## bootptab File Format

### Purpose

Default configuration database for the Internet Boot Protocol server (**bootpd**).

### Description

The **bootpd** configuration file contains entries for clients that use the **bootpd** daemon to get boot information. This file may be modified using the System Management Interface Tool (SMIT) to configure a Diskless client or the file may be modified manually.

The client host information consists of case-sensitive tag symbols used to represent host parameters. These host parameter declarations are separated by : (colon). For example:

HostName:Tg=Value:Tg=Value:Tg=Value

where:

#### HostName

Specifies the name of a BOOTP client. This must always be the first field in the entry.

The **bootpd** daemon attempts to send the entire host name as it is specified in this field. However, if the host name does not fit into the reply packet, the name is shortened to the host field (up to the first period, if present) and tried again. An arbitrarily truncated host name is never sent. If nothing reasonable fits, nothing is sent.

### Guidelines and Restrictions

- Blank lines and lines beginning with # are ignored when the file is read.
- Host entries are separated from one another by new lines; a single host entry may be extended over multiple lines if the lines end with a backslash (\). However, individual host entries must not exceed 1024 characters.
- Lines in the configuration file may be longer than 80 characters.
- Tags can be displayed in any order, with the following exceptions:
  - The host name must be the first field in an entry, and
  - The hardware type must precede the hardware address.

bootpd command

# cgaparams.sec File Format for TCP/IP

## Purpose

Defines the Cryptographically Generated Address (CGA) parameter keywords for the **ndpd-host** daemon and the **autoconf6** command.

## Description

The **/etc/ndpd/cgaparams.sec** file is the default CGA parameters file for the **ndpd-host** daemon and the **autoconf6** application. If the **ndpd-host** daemon or the **autoconf6** application is started without specifying an alternate file through the **/etc/ndpd/ndpdh.cnf** file or a user-specified configuration file, then the **ndpd-host** daemon and the **autoconf6** application read the **/etc/ndpd/cgaparams.sec** file. The **/etc/ndpd/cgaparams.sec** file provides information about enabling the SEND mode with interface.

**Prerequisite:** To enable the SEND mode, the **clic.rte** fileset and **OpenSSL** must be installed.

The **cgaparams.sec** file has the following format when configuring the **ndpd-host** daemon or the **autoconf6** application:

| Keyword                                  | Value              | Description                                                   |
|------------------------------------------|--------------------|---------------------------------------------------------------|
| <i>en&lt;value&gt; { CGA key words }</i> | 0 through <i>n</i> | Specifies the interface that is configured with the SEND mode |

The values and meanings of CGA keywords are listed in the table as follows:

| Keyword                       | Value                    | Description                                                                                                                                                                                                                                                                                                                            |
|-------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BEGIN_RSA_PRIVATE_KEY <value> | ASN1 encoded private key | Private key to be used for creating the RSA Signature                                                                                                                                                                                                                                                                                  |
| >END_RSA_PRIVATE_KEY <value>  |                          |                                                                                                                                                                                                                                                                                                                                        |
| BEGIN_RSA_PUBLIC_KEY <value>  | ASN1 encoded public key  | Public key to be embedded in CGA options                                                                                                                                                                                                                                                                                               |
| END_RSA_PUBLIC_KEY <value>    |                          |                                                                                                                                                                                                                                                                                                                                        |
| SEND <value>                  | off, compatible, only    | Specifies the SEND mode. The SEND parameter can be specified with one of the following values:                                                                                                                                                                                                                                         |
|                               | off                      | Specifies that the SEND mode is not enabled. The host will behave as it did prior to RFC 3971/3972.                                                                                                                                                                                                                                    |
|                               | compatible               | Specifies that the interface complies to RFC 3971/3972 when it sends out messages. It does not require the SEND options in the incoming message. This allows a mixed environment where certain routers are SEND-capable while others are not. However, if the SEND options are embedded in the incoming packets, they must be correct. |
|                               | only                     | Specifies that the entire message must conform to RFC 3971/3972, or the message will be rejected.                                                                                                                                                                                                                                      |

## Character Set Description (**charmap**) Source File Format

### Purpose

Defines character symbols as character encodings.

### Description

The character set description (**charmap**) source file defines character symbols as character encodings. The **/usr/lib/nls/charmap** directory contains **charmap** source files for supported locales. The **localeddef** command recognizes two sections in **charmap** source files, the **CHARMAP** section and the **CHARSETID** section:

| Item             | Description                                                                                                   |
|------------------|---------------------------------------------------------------------------------------------------------------|
| <b>CHARMAP</b>   | Maps symbolic character names to code points. This section must precede all other sections, and is mandatory. |
| <b>CHARSETID</b> | Maps the code points within the code set to a character set ID. This sections is optional.                    |

### The CHARMAP Section

The **CHARMAP** section of the **charmap** file maps symbolic character names to code points. All supported code sets have the portable character set as a proper subset. Only symbols that are not defined in the portable character set must be defined in the **CHARMAP** section. The portable character set consists of the following character symbols (listed by their standardized symbolic names) and encodings:

| Symbol Name       | Code (hexadecimal) |
|-------------------|--------------------|
| <NUL>             | 000                |
| <SOH>             | 001                |
| <STX>             | 002                |
| <ETX>             | 003                |
| <EOT>             | 004                |
| <ENQ>             | 005                |
| <ACK>             | 006                |
| <alert>           | 007                |
| <backspace>       | 008                |
| <tab>             | 009                |
| <new-line>        | 00A                |
| <vertical-tab>    | 00B                |
| <form-feed>       | 00C                |
| <carriage-return> | 00D                |
| <SO>              | 00E                |
| <SI>              | 00F                |
| <DLE>             | 010                |

The **CHARMAP** section contains the following sections:

- The CHARMAP section header.
- An optional special symbolic name-declarations section. The symbolic name and value must be separated by one or more blank characters. The following are the special symbolic names and their meanings:

| Item                               | Description                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;code_set_name&gt;</code> | Specifies the name of the coded character set for which the <b>charmap</b> file is defined. This value determines the value returned by the <b>nl_langinfo</b> subroutine. The <code>&lt;code_set_name&gt;</code> must be specified using any character from the portable character set, except for control and space characters. |
| <code>&lt;mb_cur_max&gt;</code>    | Specifies the maximum number of bytes in a multibyte character for the encoded character set. Valid values are 1 to 4. The default value is 1.                                                                                                                                                                                    |
| <code>&lt;mb_cur_min&gt;</code>    | Specifies the minimum number of bytes in a multibyte character for the encoded character set. Since all supported code sets have the portable character set as a proper subset, this value must be 1.                                                                                                                             |
| <code>&lt;escape_char&gt;</code>   | Specifies the escape character that indicates encodings in hexadecimal or octal notation. The default value is a \ (backslash).                                                                                                                                                                                                   |
| <code>&lt;comment_char&gt;</code>  | Specifies the character used to indicate a comment within a <b>charmap</b> file. The default value is a # (pound sign). With the exception of optional comments following a character symbol encoding, comments must start with a comment character in the first column of a line.                                                |

- Character set mapping statements for the defined code set.

Each statement in this section defines a symbolic name for a character encoding. A character symbol begins with the < (less-than) character and ends with the > (greater-than) character. The characters between the < (less-than) and > (greater-than) can be any characters from the portable character set, except for control and space characters. The > (greater-than) character may be used if it is escaped with the escape character (as specified by the `<escape_char>` special symbolic name). A character symbol cannot exceed 32 characters in length.

The format of a character symbol definition is:

```
<char_symbol> encoding
 optional comment
```

An encoding is specified as one or more character constants, with the maximum number of character constants specified by the `<mb_cur_max>` special symbolic name. The **localedef** command supports decimal, octal, and hexadecimal constants with the following formats:

|                      |                    |
|----------------------|--------------------|
| hexadecimal constant | <code>\xddd</code> |
| octal constant       | <code>\odd़</code> |
| decimal constant     | <code>\ddd़</code> |

Some examples of character symbol definitions are:

|                            |                       |                                 |
|----------------------------|-----------------------|---------------------------------|
| <code>&lt;A&gt;</code>     | <code>\d65</code>     | decimal constant                |
| <code>&lt;B&gt;</code>     | <code>\x42</code>     | hexadecimal constant            |
| <code>&lt;j0101&gt;</code> | <code>\x81\ddd</code> | mixed hex and decimal constants |

A range of one or more symbolic names and corresponding encoding values may also be defined, where the nonnumeric prefix for each symbolic name is common, and the numeric portion of the second symbolic name is equal to or greater than the numeric portion of the first symbolic name. In this format, a symbolic name value consists of zero or more nonnumeric characters followed by an integer of one or more decimal digits. This format defines a series of symbolic names. For example, the string `<j0101>...<j0104>` is interpreted as the `<j0101>`, `<j0102>`, `<j0103>`, and `<j0104>` symbolic names, in that order.

In statements defining ranges of symbolic names, the encoded value is the value for the first symbolic name in the range. Subsequent symbolic names have encoding values in increasing order. For example:

```
<j0101>...<j0104> \d129\ddd
```

This character set mapping statement is interpreted as follows:

|                            |                         |
|----------------------------|-------------------------|
| <code>&lt;j0101&gt;</code> | <code>\d129\ddd</code>  |
| <code>&lt;j0102&gt;</code> | <code>\d129\ddd5</code> |
| <code>&lt;j0103&gt;</code> | <code>\d130\d0</code>   |
| <code>&lt;j0104&gt;</code> | <code>\d130\d1</code>   |

Symbolic names must be unique, but two or more symbolic names can have the same value.

- The END CHARMAP section trailer.

## Examples

The following is an example of a portion of a possible **CHARMAP** section from a **charmap** file:

```

CHARMAP
<code_set_name> ISO8859-1
<mb_cur_max> 1
<mb_cur_min> 1
<escape_char> \
<comment_char> #
<NUL> \x00
<SOH> \x01
<STX> \x02
<ETX> \x03
<EOT> \x04
<ENQ> \x05
<ACK> \x06
<alert> \x07
<backspace> \x09
<tab> \x09
<newline> \x0a
<vertical-tab> \x0b
<form-feed> \x0c
<carriage-return> \x0d
END CHARMAP

```

## The CHARSETID Section

The **CHARSETID** section maps the code points within the code set to a character set ID. The **CHARSETID** section contains the following sections:

- The **CHARSETID** section header.
- Character set ID mappings for the defined code sets.
- The **END CHARSETID** section trailer.

Character set ID mappings are defined by listing symbolic names or code points for symbolic names and their associated character set IDs. The following are possible formats for a character set ID mapping statement:

|                                         |        |
|-----------------------------------------|--------|
| <character_symbol>                      | number |
| <character_symbol>...<character_symbol> | number |
| character_constant                      | number |
| character_constant...character_constant | number |

The <character\_symbol> used must have previously been defined in the **CHARMAP** section. The character\_constant must follow the format described for the **CHARMAP** section.

Individual character set mappings are accomplished by indicating either the symbolic name (defined in the **CHARMAP** section or the portable character set) followed by the character set ID, or the code point associated with a symbolic name followed by the character set ID value. Symbolic names and code points must be separated from a character set ID value by one or more blank characters. Ranges of code points can be mapped to a character set ID value by indicating appropriate combinations of symbolic names and code point values as endpoints to the range, separated by ... (ellipsis) to indicate the intermediate characters, and followed by the character set ID for the range. The first endpoint value must be less than or equal to the second end point value.

## Examples

The following is an example of a portion of a possible **CHARSETID** section from a **charmap** file:

```

CHARSETID
<space>...<nobreakspace> 0
<tilde>...<y-diaeresis> 1
END CHARSETID

```

## core File Format

### Purpose

Contains an image of a process at the time of an error.

### Description

A **.core** file is created in the current directory when various errors occur. Errors such as memory-address violations, illegal instructions, bus errors, and user-generated quit signals, commonly cause this *core dump*. The **core** file that is created contains a memory image of the terminated process. If the faulty process is multi-threaded and the current **core** size **ulimit** is less than what is required to dump the data section, then only the faulting thread stack area is dumped from the data section.

**Note:** The core dump file can be given a unique name by using the **chcore** command. The default behavior is the same as in previous versions of the AIX operating system.

Any shared memory allocated by the process may also be optionally omitted from the core file. This data is only omitted if the **CORE\_NOSHM** environment variable is exported. The default is to include all shared memory in the core file. The **CORE\_NOSHM** variable can be set to any value.

Unique core file naming will only be enabled if the environment variable **CORE\_NAMING** is exported. The default name is **core** as in previous releases. The value of the variable should be set to true.

The contents of a core dump are organized sequentially in the **core** file as follows:

| Item                      | Description                                                                                                                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Core header               | Defines basic information about the core dump, and contains offsets that locate the remainder of the core dump information.                                                                              |
| <b>ldinfo</b> structures  | Defines loader information.                                                                                                                                                                              |
| <b>mstsave</b> structures | Defines kernel thread state information. Since the faulting thread <b>mstsave</b> structure is directly saved in the core header, additional structures are saved here only for multi-threaded programs. |
| Default user stack        | Contains a copy of the user stack at the time of the core dump.                                                                                                                                          |
| Default data area         | (Optional) Contains the user data section.                                                                                                                                                               |
| Memory mapped regions     | (Optional) Contains the anonymously mapped regions.                                                                                                                                                      |
| <b>vm_info</b> structures | (Optional) Contains offset and size information for memory mapped regions.                                                                                                                               |

By default, the user data is, anonymously mapped regions, and **vm\_info** structures are not included in a core dump. This partial core dump includes the current process stack, thread stack, the thread **mstsave**

structures, the user structure, and the state of the registers at the time of the fault. A partial core dump contains sufficient information for a stack traceback. The size of a core dump can also be limited by the **setrlimit** subroutine.

To enable a full core dump, set the **SA\_FULLDUMP** flag in the **sigaction** subroutine for the signal that is to generate a full core dump. If this flag is set when the core is dumped, the data section is, anonymously mapped regions, and **vm\_info** structures are included in the core dump.

Core files are dumped in the following ways:

- All dumped cores are in the context of the running process. They are dumped with an owner and a group matching the effective user ID (UID) and group ID (GID) of the process. If this UID/GID pair does not have permission to write to the target directory that is determined according to the standard core path procedures, no core file is dumped.
- If the real user ID (RUID) is root, the core file can always be dumped, but with a mode of 0600.
- If the effective user ID (EUID) matches the real user ID (RUID), and the effective group ID (EGID) matches any group in the credential's group list, the core file is dumped with permissions of 0600.
- If the EUID matches the RUID, but the EGID does not match any group in the credential's group list, the core file cannot be dumped. The effective user cannot see data that they do not have access to.
- If the EUID does not match the RUID, the core file can be dumped only if you have set a core directory using the **syscorepath** command. This avoids dumping the core file into either the current working directory or a user-specific core directory in such a way that you cannot remove the core file. Core is dumped with a mode of 0600. If you have not used the **syscorepath** command to set a core directory, no core is dumped.

The format of the core header is defined by the **core\_dump** structure (in the **core.h** header file), which is organized as follows:

| Item               | Field Name            | Description                                                                              |
|--------------------|-----------------------|------------------------------------------------------------------------------------------|
| char               | c_signo               | The number of the signal which caused the error.                                         |
| char               | c_flag                | A bit field which describes the core dump type. The meanings of the bits are as follows: |
|                    | <b>FULL_CORE</b>      | core contains the data sections (0x01)                                                   |
|                    | <b>CORE_VERSION_1</b> | core was generated by AIX Version 4 or higher (0x02)                                     |
|                    | <b>MSTS_VALID</b>     | core contains msts save structures (0x04)                                                |
|                    | <b>CORE_BIGDATA</b>   | core contains big data (0x08)                                                            |
|                    | <b>UBLOCK_VALID</b>   | core contains the u_block structure (0x10)                                               |
|                    | <b>USTACK_VALID</b>   | core contains the user stack (0x20)                                                      |
|                    | <b>LE_VALID</b>       | core contains at least one module (0x40)                                                 |
|                    | <b>CORE_TRUNC</b>     | core was truncated (0x80)                                                                |
| ushort             | c_entries             | The number of core dump modules                                                          |
| struct ld_info *   | c_tab                 | The offset to the beginning of the core table                                            |
| caddr_t            | c_stack               | The offset to the beginning of the user stack                                            |
| int                | c_size                | The size of the user stack                                                               |
| struct msts save   | c_mst                 | A copy of the faulting mst                                                               |
| struct user        | c_u                   | A copy of the user structure                                                             |
| int                | c_nmsts               | The number of <b>msts save</b> structures referenced by the c_msts field                 |
| struct msts save * | c_msts                | The offset to the other threads' <b>msts save</b> structures                             |

| Item             | Field Name  | Description                                  |
|------------------|-------------|----------------------------------------------|
| int              | c_datasize  | The size of the data region                  |
| caddr_t          | c_data      | The offset to user data                      |
| int              | c_vmrégions | The number of anonymously mapped regions     |
| struct vm_info * | c_vmm       | The offset to the start of the vm_info table |

## cpio File Format

### Purpose

Describes the copy in/out (**cpio**) archive file.

### Description

The **cpio** utility backs up and recovers files. The files are saved on the backup medium in the **cpio** format.

When the **cpio** command is used with the **-c** flag, the header for the **cpio** structure reads as follows:

```
sscanf(Chdr,"%6ho%6ho%6ho%6ho%6ho%6ho%11lo%6ho%11lo%s",
&Hdr.h_magic, &Hdr.h_dev, &Hdr.h_ino, &Hdr.h_mode,
&Hdr.h_uid, &Hdr.h_gid, &Hdr.h_nlink, &Hdr.h_rdev,
&Longtime, &Hdr.h_namesize, &Longfile, &Hdr.h_name);
```

Longtime and Longfile are equivalent to Hdr.h\_mtime and Hdr.h\_filesize, respectively. The contents of each file, and other items describing the file, are recorded in an element of the array of structures with varying lengths.

**Note:** Files saved with the **-c** flag must be restored with the **-c** flag.

When the **-c** flag of the **cpio** command is not used, the header structure contains the following fields:

| Item    | Description                                                      |
|---------|------------------------------------------------------------------|
| h_magic | Contains the constant octal 070707 (or 0x71c7).                  |
| h_dev   | Device that contains a directory entry for this file.            |
| h_ino   | I-node number that identifies the input file to the file system. |
| h_mode  | Mode of the input file, as defined in the <b>mode.h</b> file.    |
| h_uid   | User ID of the owner of the input file.                          |
| h_gid   | Group ID of the owner of the input file.                         |

For remote files, these fields contain the ID after reverse translation:

| Item       | Description                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| h_nlink    | Number of links that are connected to the input file.                                                                                                                                                                                                                                                                                                                                                       |
| h_rdev     | ID of the remote device from which the input file is taken.                                                                                                                                                                                                                                                                                                                                                 |
| h_mtime    | Time when data was last modified. For remote files, this field contains the time at the server. This time can be changed by the <b>creat</b> , <b>fclearf</b> , <b>truncate</b> , <b>mknod</b> , <b>openx</b> , <b>pipe</b> , <b>utime</b> , or <b>writex</b> subroutine.                                                                                                                                   |
| h_namesize | Length of the path name, including the terminating null byte.                                                                                                                                                                                                                                                                                                                                               |
| h_filesize | Length of the file in bytes. This is the length of the data section that follows the header structure.                                                                                                                                                                                                                                                                                                      |
| h_name     | Null-terminated path name. The length of the path name, including the null byte, is indicated by the <i>n</i> variable, where <i>n</i> equals $(h\_namesize \% 2) + h\_namesize$ . That is, the <i>n</i> variable is equal to the <b>h_namesize</b> field if the <b>h_namesize</b> field is even. If the <b>h_namesize</b> field is odd, the <i>n</i> variable is equal to the <b>h_namesize</b> field + 1. |

The last record of the archive always contains the name TRAILER!!!. Special files, directories, and the trailer are recorded with the **h\_filesize** field equal to 0.

## cronlog.conf File

### Purpose

Specifies the default configuration file of the **cron** daemon for logging information.

### Description

The **cronlog.conf** configuration file informs the **cron** daemon where and how to log information. If you do not use the **-f** flag, the **cron** daemon reads the default **/etc/cronlog.conf** configuration file. If the **cron** daemon fails to open the configuration file, it continues with the **/var/adm/cron/log** file. The **cron** daemon ignores blank lines and lines beginning with a # (pound sign).

### Format

#### archive

Specifies that the saved rotated files will be copied to a directory. It is followed by the directory name. If archive is not specified and rotation is valid, files are rotated in the directory of **logfile**.

#### compress

Specifies that the saved rotated files will be compressed. If keyword is not present then no compression is done.

**logfile** Specifies the full path name of the log file. If the file does not exist, it is created with permission 660. Do not create the log file in the "/" file system. If the **cron** daemon cannot create the name of the log file, the daemon creates a log of its activities in the **/var/adm/cron/log** file, and all of the features below it are turned off.

**quiet** Specifies that **cron** logging will be disabled.

**rotate** Specifies the total number of rotated files. It is followed by a number. If a number is not specified then there are unlimited number of rotated files. If the **rotate** keyword is not present, then no rotation is done. If specified, minimum of number of rotated files is 2.

**size** Limits the size of a *logfile*. It is followed by a number and either a **k** (kilobytes) or **m** (megabytes). The default and minimum size is 30K. If the size value is invalid then rotation feature is turned off.

## Examples

1. To log information in the directory **/home/user**, log file **cron.out**, size of 2M , total number of rotated files = 4, archive in **/usr/home**, compress archive files, create the configuration file as follows:

```
logfile=/home/user/cron.out
size=2m
rotate=4
archive=/usr/home
compress
```

2. To log information in directory **/home/user**, log file **cron.out**, size of 50k , unlimited log files, archive in **/usr/home**, compress archive files, create the configuration file as follows:

```
logfile=/home/user/cron.out
size=50k
rotate
archive=/usr/home
compress
```

3. To log information in directory **/home/user**, log file **cron.out**, size of 50k , total number of rotated files = 4, create the configuration file as follows:

```
logfile=/home/user/cron.out
size=50K
rotate=4
```

4. To log information in directory **/home/user**, log file **cron.out**, size of 50k , total number of rotated files = 4, archive in **/usr/home**, archive files without compression, no logging of cron jobs, create the configuration file as follows:

```
logfile=/home/user/cron.out
size=50K
rotate=4
archive=/usr/home
quiet
```

In this case, **cron.out** will contain only debug or error messages.

## Devices File Format for BNU

### Purpose

Contains information about devices on the local system that can establish a connection to a remote computer using the Basic Networking Utilities (BNU) program.

### Description

The **/etc/uucp/Devices** file and its augmentations and alternatives specified in the **/etc/uucp/ Sysfiles** file contains information about the devices on the local system that can establish a connection to a remote computer using the Basic Networking Utilities (BNU) program. This file includes information for hardwired, telephone, and TCP/IP communication links.

**Note:** Only someone with root user authority can edit the **Devices** file, which is owned by the **uucp** login ID.

### Fields in the Devices File

The **Devices** file must contain a description of each device on the local system that can establish a remote connection using the BNU program. Each line in the **Devices** file includes the following fields:

| Item                      | Description                                                                                                                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Type</i>               | Typically specifies the type of hardwired or automatic calling unit (ACU) device.                                                                                                                             |
| <i>Line</i>               | Specifies the device name for the port.                                                                                                                                                                       |
| <i>Line2</i>              | Specifies the dialer name if the <i>Line</i> entry specifies an 801 dialer.                                                                                                                                   |
| <i>Class</i>              | Typically specifies the transmission speed.                                                                                                                                                                   |
| <i>Dialer-Token Pairs</i> | Specifies a particular type of autodialer (modem) and the token (a defined string of characters) that is passed to the dialer. Valid entries for this field are defined in the <i>/etc/uucp/Dialers</i> file. |

The fields appear on the line as follows:

*Type Line Line2 Class Dialer-Token Pairs*

Every field of a line in the **Devices** file must contain an entry. If a field does not apply to the particular type of device or system, use a - (minus sign) as a placeholder.

Lines in the **Devices** file cannot wrap. Each entry must be on only one line in the file. However, the **Devices** file can contain blank lines and comment lines. Comment lines begin with a # (pound sign). Blank lines are ignored.

### Type Field

Enter one of the following keywords in this field:

| Keyword           | Explanation                                                                                                                                                                              |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACU               | Use this keyword, entered in uppercase letters, if your site connects multiple systems over the telephone network with automatic calling units (autodialers or modems).                  |
| Direct            | Use this keyword, beginning with an uppercase D, if your site uses hardwired lines to connect multiple systems.                                                                          |
| TCP               | Use this keyword, in uppercase letters, if your site uses TCP/IP.                                                                                                                        |
| <i>SystemName</i> | Enter the name of a particular remote system hardwired to the local system. The <i>SystemName</i> keyword is the name assigned to each individual system, such as hera, zeus, or merlin. |

This field corresponds to the *Type* field in the */etc/uucp/Systems* file.

### Line Field

The device name for the line, or port, used in the communication link is inserted here. For example, use the appropriate device name for a hardwired line, such as *tty1*. For a line connected to an ACU (a modem), use a device name appropriate to the dialer, such as *tty1* or *tty2*. For a TCP connection, enter a minus sign as a placeholder.

### Line2 Field

Unless you are using an 801 dialer, use a - (minus sign) in this field as a placeholder. If you are using an 801 dialer, put the device name of the 801 ACU in this field. For example, if the entry in the *Type* field is ACU and the *Line* field entry (specifying the modem) is *tty1*, the *Line2* field entry (specifying the 801 dialer for the modem) might be *tty3* or *tty4*.

**Note:** The *Line2* field is used only to support older modems that require 801-type dialers. The modem is plugged into one serial port, and the 801 dialer is plugged into a separate serial port.

### Class Field

For an ACU or a hardwired line, the *Class* field can be the speed of the device. In this case, for a hardwired line, use the transmission rate of the device connecting the two systems. For a telephone connection, use the speed at which the ACU transmits data, such as 300 or 1200 bps.

This field can also contain a letter with a speed (for example, C1200 or 1200) to differentiate between classes of dialers. For example, some offices have more than one telephone network, one for internal use and one for external communications. In such a case, it is necessary to distinguish which lines should be used for each connection.

The *Class* field in the **Devices** file is matched against the *Class* field in the **/etc/uucp/Systems** file. For example, if the **Systems** file entry for system hera is:

```
hera Any ACU 1200 3-3-5-2 ogin: nuucp ssword: oldoaktree
```

BNU searches for an entry in the **Devices** file with a *Type* of ACU and a *Class* of 1200.

Some devices can be used at several specific speeds. In this case, make multiple entries for the device, specifying each speed on a separate line in the **Devices** file. If BNU cannot connect at the first speed, it will try the successive speeds.

If a device can be used at any speed, type the word *Any* in the *Class* field. Note that the *A* in *Any* must be uppercase.

For a TCP/IP connection, enter a - (minus sign) as a placeholder.

#### Dialer-Token Pair Field

The *Dialer-Token Pair* field specifies a particular type of autodialer (modem) and the token (a defined string of characters) that is passed to the dialer. Valid entries for this field are defined in the **/etc/uucp/Dialers** file.

For a hardwired connection, enter the word *direct* (note the lowercase *d*) as the *Dialer* entry and leave the *Token* entry blank.

For a telephone connection, enter the type of dialer and the token that is passed to that modem. The *Token* field entry is either a telephone number or a predefined string used to reach the dialer.

For a telephone connection, enter one of the following as the *Dialer* field entry:

| Entry         | Definition                                                                                                             |
|---------------|------------------------------------------------------------------------------------------------------------------------|
| hayes         | A Hayes dialer.                                                                                                        |
| Other Dialers | Other dialers that you can specify by including the relevant information in the <b>/etc/uucp/Dialers</b> file.         |
| TCP           | A TCP/IP connection. Enter TCP in the <i>Dialer</i> field entry if you have also entered TCP in the <i>Type</i> field. |

Each *Dialer* field entry included as part of a *Dialer-Token Pair* field in the **Devices** file has a corresponding entry in the **Dialers** file.

If the *Token* field entry represents a telephone number, enter one of the following in the *Token* field to specify how the BNU program should use the telephone number listed in the **/etc/uucp/Systems** file:

| <b>Entry</b> | <b>Definition</b>                                                                                                                                                                                                                                                                                                                                              |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \D           | The default token in a <i>Dialer-Token Pair</i> field. The \D token specifies that the BNU program should take the phone number listed in the /etc/uucp/Systems file and pass it to the appropriate <i>dialer script</i> (entry) in the /etc/uucp/Dialers file, <i>without</i> including a dial-code abbreviation.                                             |
| \T           | This token instructs the BNU program to process the phone number by including the data specified in the /etc/uucp/Dialcodes file.<br><b>Note:</b> If you are using dial-code abbreviations specified in the <b>Dialcodes</b> file for certain telephone numbers, you <i>must</i> enter the \T string as the token in those entries in the <b>Dialers</b> file. |
| blank        | Leaving the <i>Token</i> field blank is the same as entering \D, so a blank is usually sufficient as a token if you have included complete telephone numbers in the /etc/uucp/Systems file.                                                                                                                                                                    |
|              | If the <i>Token</i> field does not represent a telephone number, enter the predefined string necessary to reach the dialer.                                                                                                                                                                                                                                    |

## Examples

### Setting Up Entries for Hardwired Connections

To set up a **Device** file entry specifying a port and a remote system, make an entry as follows:

```
Direct tty1 - 1200 direct
zeus tty1 - 1200 direct
```

The *Type* field lists Direct (for a direct connection) in the first part and zeus (the name of the remote system) in the second part. The local system is connected to system zeus by way of device tty1, which is listed in the *Line* field in both parts of the example.

The *Line2* field contains actual data only when the entry specifies a certain type of telephone connection. A - (minus sign) is used as a placeholder in other types of connections, as in this example. This device transmits at a rate of 1200 bps, which is listed in the *Class* field in both parts of the example. The word direct in the *Dialer* field portion of the *Dialer-Token Pair* field indicates that this is a direct connection.

### Setting Up Entries for Autodialer Connections

- For a standard Hayes modem that can be used at only one baud rate, make an entry as follows:

```
ACU tty2 - 1200 hayes
```

The *Type* field is specified as ACU. The *Line* field is specified with the device name tty2. Because this modem is not an 801 dialer, a - (minus sign) is used as a placeholder in the *Line2* field. The *Class* field entry is a transmission rate of 1200 baud. The *Dialer* field part of the *Dialer-Token Pair* field is specified as a hayes modem, and the *Token* field part is left blank.

- To specify a standard Hayes modem that can be used at different baud rates, make an entry as follows:

```
ACU tty3 - 1200 hayes
ACU tty3 - 300 hayes
```

These two lines specify the same modem, a hayes, which can be used at either 1200 or 300 baud, as specified in the *Class* field. The modem is connected to a device named tty3 (the *Line* field), and the *Line2* field contains the - (minus sign) placeholder. The *Dialer* field part of the *Dialer-Token Pair* field is specified as a hayes modem, and the *Token* field is left blank.

- To specify a standard Hayes modem that can be used at any baud rate, make an entry as follows:

```
ACU tty2 - Any hayes
```

These two lines specify a hayes modem that can be used at any baud rate, as specified by the word Any entered in the *Class* field. Note that the word Any must be entered with an uppercase A.

- To specify a connection using a standard 801 dialer, make an entry as follows:

```
ACU tty4 tty5 1200 801
ACU tty6 tty7 300 801
```

In these entries, the ACU entries are connected to devices named tty4 and tty6, specified in the *Line* field. In both cases, there is an entry in the *Line2* field because a standard 801 autodialer is specified in the *Dialer-Token Pair* field. Because 801 is specified as the dialer in these two examples, the *Line2* field must contain the device names of the 801 ACUs. The *Class* field entry specifies a transmission rate of 1200 baud for the first example and 300 for the second. The *Token* field part of the *Dialer-Token Pair* field is blank.

### Setting Up the Entry for Use with TCP/IP

If your site is using the TCP/IP system, enter the following in the **Devices** file:

```
TCP - - - TCP
```

TCP is specified in the *Type* field. minus signs are used as placeholders in the *Line*, *Line2*, and *Class* fields. TCP is specified as the *Dialer* field entry, with the *Token* entry left blank.

### Setting Up Entries for Both Local and Remote Systems

The following examples illustrate the entries needed in the **Devices** file for both local and remote systems in order for the two systems to communicate using the BNU program.

1. To configure a hardwired connection, note the following information.

The following entries configure local and remote **Devices** files for a hardwired connection between systems zeus and hera, where zeus is considered the local system and hera the remote system. The hardwired device on system zeus is tty1; on system hera, it is tty2.

The **Devices** file on system zeus contains the following entry in order to connect to the remote system, hera:

```
Direct tty1 - 1200 direct
hera tty1 - 1200 direct
```

The **Devices** file on system hera contains the following entry for communications with system zeus:

```
Direct tty2 - 1200 direct
zeus tty2 - 1200 direct
```

2. To configure a telephone connection, note the following information.

These files are set up to connect systems venus and merlin over a telephone line using modems.

System venus is considered the local system, and system merlin is considered the remote system.

On both systems, the device tty1 is hooked to a hayes modem at 1200 baud. Both computers include partial phone numbers in their **/etc/uucp/Systems** files and dialing codes in their **/etc/uucp/Dialcodes** files.

The **Devices** file on system venus contains the following entry for the connection to system merlin:

```
ACU tty1 - 1200 hayes \T
```

The **Devices** file on system merlin contains the following entry for the connection to system venus:

```
ACU tty1 - 1200 hayes \T
```

## Files

| Item                     | Description                                                                      |
|--------------------------|----------------------------------------------------------------------------------|
| /etc/uucp directory      | Contains all the configuration files for BNU, including the <b>Devices</b> file. |
| /etc/uucp/Dialcodes file | Contains dialing code abbreviations.                                             |
| /etc/uucp/Dialers file   | Specifies initial handshaking on a connection.                                   |
| /etc/uucp/Systems file   | Describes accessible remote systems.                                             |
| /etc/uucp/Sysfiles file  | Specifies possible alternative or augmentative files for /etc/uucp/Devices.      |

Editing Devices File for Hardwired Connections

## Dialcodes File Format for BNU

### Purpose

Contains the initial digits of telephone numbers used to establish remote connections over a phone line.

### Description

The **/etc/uucp/Dialcodes** file contains the initial digits of telephone numbers used by the Basic Networking Utilities (BNU) program to establish remote connections over a phone line. The **Dialcodes** file simplifies entries in the **/etc/uucp/Systems** file for sites where a number of device phone numbers have the same prefix.

If users at your site communicate regularly by way of telephone lines and modems to multiple systems all located at the same remote site, or to multiple systems located at different remote sites, use the dial-code abbreviations in the **/etc/uucp/Systems** file rather than entering the complete phone number of each remote modem in that file.

The **Dialcodes** file contains dial-code abbreviations and partial phone numbers that complete the telephone entries in the **/etc/uucp/Systems** file. Entries in the **Dialcodes** file contain an alphabetic prefix attached to a partial phone number that may include the following information in the order listed:

- Codes for an outside line
- Long-distance access codes
- A 1 (one) plus the area code (if the modem is out of the local area)
- The three-digit exchange number

The relevant alphabetic prefix (representing the partial phone number), together with the remaining four digits of that number, is then entered in the *Phone* field in the **/etc/uucp/Systems** file.

Following is the form of an entry in a **Dialcodes** file:

*DialCodeAbbreviation DialingSequence*

The *DialCodeAbbreviation* part of the entry is an alphabetic prefix containing up to 8 letters, established when setting up the dialing-code listing. The *DialingSequence* is composed of all the digits in the number that precede the actual four-digit phone number.

**Note:**

1. If your site uses only a relatively small number of telephone connections to remote systems, include the complete phone numbers of the remote modems in the **/etc/uucp/Systems** file rather than use dial-code abbreviations.
2. Enter each prefix *only once* in the **Dialcodes** file. When you have set up a dial-code abbreviation, use that prefix in all relevant entries in the **/etc/uucp/Systems** file.
3. Only someone with root user authority can edit the **Dialcodes** file, which is owned by the **uucp** program login ID.

## **Example**

The **Dialcodes** file on system venus contains the following dial-code prefix for use with a number in the **/etc/uucp/Systems** file:

```
local 9=445
```

The **Systems** file on system venus contains the following entry for system zeus, including a phone number and a dialing prefix:

```
zeus Any ACU 1200 local8784 in:--in: uzeus word: thunder
```

When BNU on system venus dials system zeus, BNU uses the expanded telephone number 9=4458784.

## **Files**

| Item                           | Description                                                                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>/etc/uucp</b> directory     | Contains all the configuration files for BNU, including the <b>Dialcodes</b> file.                                                       |
| <b>/etc/uucp/Devices</b> file  | Contains information about available devices.                                                                                            |
| <b>/etc/uucp/Dialers</b> file  | Specifies initial handshaking on a connection.                                                                                           |
| <b>/etc/uucp/Systems</b> file  | Describes accessible remote systems.                                                                                                     |
| <b>/etc/uucp/Sysfiles</b> file | Specifies possible files used instead of <b>/etc/uucp/System</b> file, <b>/etc/uucp/Devices</b> file, and <b>/etc/uucp/Dialers</b> file. |

## **Dialers File Format for BNU**

### **Purpose**

Lists modems used for Basic Networking Utilities (BNU) remote communications links.

### **Description**

The **/etc/uucp/Dialers** file and its surrogates, specified in the **/etc/uucp/Sysfiles** file, lists the modems (dialers) used by the Basic Networking Utilities (BNU) program and specifies the initial handshaking necessary to establish remote communications links. Handshaking is a series of expect-send sequences that specify the initial communications that occur on a link before it is ready to send or receive data. Using the handshaking, the local and remote systems confirm that they are compatible and configured to transfer data.

The **Dialers** file(s) contains entries for each autodialer that is included in the **/etc/uucp/Devices** file or one of its surrogate files. Surrogate file are specified in the **/etc/uucp/Sysfiles** file. It also contains entries specifying no handshaking for direct hardware links (the direct entry) and TCP/IP links (the TCP

entry). The first field of the **Dialers** file, which specifies the dialer, is matched to the fifth field of the **Devices** file, the *Dialer-Token Pair* field, to determine handshaking when making a connection.

**Note:** Only someone with root user authority can edit the **Dialers** file, which is owned by the **uucp** login ID.

## Fields in a Dialers File

Every modem (dialer) is listed on a line by itself in the **Dialers** file. Each line consists of three groups of information: the *Dialer Name* field, the *Dial Tone and Wait Characters* field, and the *Handshaking* field.

### Dialer Name Field

The first field in a **Dialers** file, the *Dialer Name* field, specifies the type of autodialer (modem) used in the connection. It matches the fifth field, the *Dialer-Token Pair* field, in the **Devices** file(s). When a particular device is used to make a connection, BNU uses the *Dialer-Token Pair* field in the **Devices** file(s) to find the handshaking entry in the **Dialers** file(s).

If your system has direct hardware connections to one or more remote systems, include an entry with a *Dialer Name* of *direct*. Similarly, if your system uses TCP/IP to connect to one or more other systems, include an entry with a *DialerName* of *TCP*. These entries correspond, respectively, to the word *direct* and the word *TCP* in the *Dialer-Token Pairs* field of entries in a **Devices** file. Omit the *Dial Tone and Wait Characters* field and the *Handshaking* field, since no handshaking is needed on these connections.

### Dial Tone and Wait Characters Field

The second field, the *Dial Tone and Wait Characters* field, consists of two sets of two characters, for a total of four entries. These characters comprise a translation string. In the actual phone number of the remote modem, the first character in each string is mapped to the second character in that set.

| Entry  | Action                                                                                                                                   |
|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| =,-,   | Translate the telephone number. Any = (equal sign) represents <i>wait for dial tone</i> and any - (minus sign) represents <i>pause</i> . |
| ""     | Wait for nothing; continue with the rest of the string.                                                                                  |
| WAIT=n | Enter this before any send string in the Dialers file, where n is the number of seconds to wait before timing out.                       |

This field generally translates the = and - characters into whatever the dialer uses for *wait for dial tone* and *pause*.

For *direct* and *TCP* entries, omit this field.

### Handshaking Field

The handshaking, or dialer negotiations, consists of an expect-send sequence of ASCII strings. This sequence is given in the *Handshaking* field, which comprises the remainder of the entry. This string is generally used to pass telephone numbers to a modem, or to make a connection to another system on the same data switch as the local system. The string tells the **cu** or **ct** program or the **uucico** daemon the sequence of characters to use to dial out on a particular type of modem. If the connection succeeds, the appropriate line from a **Dialers** file is interpreted to perform the dialer negotiations.

The handshaking characters include the following key sequences:

| Sequence | Result                       |
|----------|------------------------------|
| \c       | Suppress new line (\n)       |
| \D       | Raw phone number             |
| \T       | Translated phone number      |
| \N       | Null character (\0)          |
| \b       | Backspace                    |
| \n       | New line                     |
| \r       | Carriage return              |
| \s       | Space                        |
| \t       | Tab                          |
| \\\      | Backslash                    |
| \E       | Turn echo check on           |
| \e       | Turn echo check off          |
| \d       | Delay two seconds            |
| \p       | Pause about 1/4 second       |
| \K       | Generate a break on the line |
| \M       | Set tty setting CLOCAL on    |
| \m       | Turn tty setting CLOCAL off  |

For direct and TCP entries, omit this field.

## Examples

### Setting Up Entries in a Dialers File

1. The following example lists several entries in a typical **Dialers** file:

```
hayes =,-, "" \dAT\r\c OK \pATDT\T
\r\c CONNECT
penril =W-P "" \d > s\p9\c)-W\p\r\ds\p9\c-
y/c : \E\
P > 9\c OK
ventel =-&- "" \r\p \r\p-\r\p-$ <K\D%%\r>\c ;ONLINE!
vadic =K-K "" \005\p *-\005\p-* D\p BER? \E\D
\c
 LINE
direct
TCP
```

**Note:** In a **Dialers** file, each entry must be entirely on one line.

Notice that the next-to-last entry in the preceding example consists only of the word **direct**. This entry indicates that hardwired connections do not require any handshaking. Similarly, the last entry, **TCP**, indicates that TCP/IP connections require no handshaking.

2. The following example interprets the first line in the preceding **Dialers** file. This is a standard entry that may be included in your **Dialers** file with modifications for use at your site.

```
hayes =,-, "" \dAT\r\c OK \pATDT\T
\r\c CONNECT
```

The first two sequences (=,-,"") comprise the *Dial Tone and Wait Characters* field. The remaining strings comprise the *Handshaking* field. Following is an explanation of how each entry affects the action of the dialer.

| Entry   | Action                                                                                                                                   |
|---------|------------------------------------------------------------------------------------------------------------------------------------------|
| =,-,    | Translate the telephone number. Any = (equal sign) represents <i>wait for dial tone</i> and any - (minus sign) represents <i>pause</i> . |
| ""      | Wait for nothing; continue with the rest of the string.                                                                                  |
| \dAT    | Delay; then send AT (the Hayes Attention prefix).                                                                                        |
| \r\c    | Send a carriage return (r) followed by a new line (c).                                                                                   |
| OK      | Wait for OK from the remote modem, signaling that the first part of the string has executed.                                             |
| \pATDT  | Pause (p); then send ATDT. AT is the Hayes Attention prefix, D represents a dialing signal, and T represents a touch-tone dial tone.     |
| \T      | Send the telephone number, which is specified in the <b>Systems</b> file, with dial-code translation from the <b>Dialcodes</b> file.     |
| \r\c    | Send a carriage return and a new line following the number.                                                                              |
| CONNECT | Wait for CONNECT from the remote modem, signaling that the modems are connected at the baud rate specified in the <b>Devices</b> file.   |

**Note:** If you need to modify this example for use at your site and are unsure about the appropriate entries in the handshaking string, refer to the documentation that accompanied the modems you are including in the **Dialers** file.

### Setting Up the Direct Entry

If your BNU configuration includes hardwired connections, a **Dialers** file must contain a direct entry, as follows:

```
direct
```

This entry indicates that hardwired connections do not require any handshaking. It corresponds to the word *direct* in the *Dialer-Token Pairs* field of entries for hardwired devices in a **Devices** file (see the /etc/uucp/Devices file).

### Setting Up the TCP/IP Entry

If your BNU configuration includes TCP/IP connections, the **Dialers** file used by the **uucico** service must contain a TCP entry, as follows:

```
TCP
```

This entry indicates that TCP/IP connections do not require any handshaking. It corresponds to the word *TCP* in the *Dialer-Token Pairs* field of entries for TCP/IP connections in the **uucico** service **Devices** file(s).

### Setting Up Entries for Both Local and Remote Systems

The following example illustrates the entries needed in the **Dialers** file to correspond to entries in the **Devices** file for both local and remote systems so that the two systems can communicate using the BNU program.

These files are set up to connect systems **venus** and **merlin** over a telephone line using modems. System **venus** is considered the local system, and system **merlin** is considered the remote system. On both systems, the device **tty1** is hooked to a **hayes** modem at 1200 baud.

- The **Devices** file on system **venus** contains the following entry for the connection to remote system **merlin**:
 

```
ACU tty1 - 1200 hayes
```
- The **Dialers** file on system **venus** contains the following entry for its modem:
 

```
hayes =,-, "" \dAT\r\c OK \pATDT\T
\r\c CONNECT
```
- The **Devices** file on system **merlin** contains the following entry for the connection to system **venus**:
 

```
ACU tty1 - 1200 hayes
```

- The **Dialers** file on system `merlin` contains the following entry for its modem:

```
hayes =,-, "" \dAT\r\c OK \pATDT\T
\r\c CONNECT
```

**Note:** The **Dialers** file and **Devices** file for the system `venus` and `merlin` can be files other than `/etc/uucp/Dialers` and `/etc/uucp/Devices`. Use of the `/etc/uucp/Sysfiles` file enables a system administrator to allow the use of one or more files on each system to replace or augment the `/etc/uucp/Dialers` and `/etc/uucp/Devices` file. See the **Sysfiles Files Format for BNU** in *Files Reference*.

### Troubleshooting Connection Problems

**Note:** The **Dialer** and **Systems** files discussed in the section can be files other than `/etc/uucp/Dialers` and `/etc/uucp/Systems`. See the **Sysfiles Files Format for BNU** in *Files Reference*.

When establishing a connection between a local and a remote system using a telephone line and modem, the BNU program consults the **Dialers** file. (The BNU program also checks the **Systems** file to make sure it contains a listing for the specified remote computer.) If users report a faulty connection, use the **uucico** command to debug the connection problem. For example, if users are experiencing difficulties connecting to remote system `venus`, issue the following command:

```
/usr/sbin/uucico -r1 -svenus -x9
```

where `-r1` specifies the server mode, `-svenus` the name of the remote system to which you are trying to connect, and `-x9` the debug level that produces the most detailed debugging information.

Expect-send debugging output produced by the **uucico** command can come either from information in the **Dialers** file or from information in the **Systems** file. If the relevant line in the **Dialers** file is not set up correctly for the specified modem, the BNU program will probably display the following error message:

```
DIALER SCRIPT FAILED
```

If the dialer script fails, verify the following:

- Make sure that both the local and the remote modems are turned on, that they are both set up correctly, and that the telephone number of the remote modem is correct.
- Check the **Dialers** file and make sure the information is correctly specified for the local modem. If possible, also check the **Dialers** file on the remote system.
- Check the documentation that came with your modem to make sure you have used the correct expect-send sequence characters in the **Dialers** file.

## Files

| Item                                  | Description                                                                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/uucp</code> directory      | Contains all the configuration files for BNU, including the <b>Dialers</b> file.                                                               |
| <code>/etc/uucp/Devices</code> file   | Contains information about available devices.                                                                                                  |
| <code>/etc/uucp/Dialcodes</code> file | Contains dialing code abbreviations.                                                                                                           |
| <code>/etc/uucp/Systems</code> file   | Describes accessible remote systems.                                                                                                           |
| <code>/etc/uucp/Sysfiles</code> file  | Specifies possible alternative files for <code>/etc/uucp/System</code> , <code>/etc/uucp/Dialers</code> , and <code>/etc/uucp/Devices</code> . |

## Dialing Directory File Format for ATE

### Purpose

Lists phone numbers used to establish modem connections.

### Description

The ATE dialing directory file lists phone numbers that the Asynchronous Terminal Emulation (ATE) uses to establish remote connections by modem.

Users name the dialing directory file with any valid file name and place it in any directory where read and write access is owned. Edit the dialing directory file with any ASCII text editor. The default dialing directory file is the **/usr/lib/dir** file.

The **connect** and **directory** subcommands of ATE access the dialing directory file. Use the **connect** command to use numbers that are not in the dialing directory file. Use the **directory** subcommand to view the dialing directory.

Users can have more than one dialing directory. To change the dialing directory file the ATE program uses, modify the **ate.def** file in the current directory.

**Note:** The dialing directory file can contain up to 20 lines (one entry per line). ATE ignores subsequent lines.

### Format of Dialing Directory File Entries

The dialing directory file is similar to a page in a telephone book. This file contains entries for the remote systems called with the ATE program. The format of a dialing directory entry is:

*Name Phone Rate Length StopBit Parity Echo Linefeed*

The fields must be separated by at least one space. More spaces can be used to make each entry easier to read. The fields are:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>     | Identifies a telephone number. The name can be any combination of 20 or fewer characters. Use the <b>_</b> (underscore) instead of a blank between words in a name, for example, <b>data_bank</b> .                                                                                                                                                                                                                                                                         |
| <i>Phone</i>    | The telephone number to be dialed. The number can be up to 40 characters. Consult the modem documentation for a list of acceptable digits and characters. For example, if a 9 must be dialed to access an outside line, include a 9 and a <b>,</b> (comma) before the telephone number as follows: <b>9,1112222</b> .<br><b>Note:</b> Although the telephone number can be up to 40 characters long, the <b>directory</b> subcommand displays only the first 26 characters. |
| <i>Rate</i>     | Transmission or baud rate in bits per second (bps). Determines the number of characters transmitted per second. Select a baud rate that is compatible with the communication line being used. The following are acceptable rates: 50, 75, 110, 134, 150, 300, 600, 1200, 1800, 2400, 4800, 9600, or 19,200.                                                                                                                                                                 |
| <i>Length</i>   | Number of bits that make up a character. The entry for the <i>Length</i> field can be 7 or 8.                                                                                                                                                                                                                                                                                                                                                                               |
| <i>StopBit</i>  | Stop bits that signal the end of a character. The entry for the <i>StopBit</i> field can be 1 or 2.                                                                                                                                                                                                                                                                                                                                                                         |
| <i>Parity</i>   | Checks whether a character was successfully transmitted to or from a remote system. The entry for the <i>Parity</i> field can be 0 (none), 1 (odd), or 2 (even).                                                                                                                                                                                                                                                                                                            |
| <i>Echo</i>     | Determines whether typed characters display locally. The entry for the <i>Echo</i> field can be 0 (off) or 1 (on).                                                                                                                                                                                                                                                                                                                                                          |
| <i>Linefeed</i> | Adds a line-feed character at the end of each line of data coming in from a remote system. The line-feed character is similar in function to the carriage-return and new-line characters. The entry for the <i>Linefeed</i> field can be 0 (off) or 1 (on).                                                                                                                                                                                                                 |

## Examples

Following is a sample dialing directory entry:

```
CompuAid 111-0000 1200 7 1 2 0 0
```

In this example, CompuAid is the *Name*, 111-0000 is the *Phone*, 1200 is the *Rate*, 7 is the *Length*, 1 is the *StopBit*, 2 is the *Parity*, the first 0 is the *Echo*, and the second 0 is the *Linefeed*.

## Files

| Item         | Description                                     |
|--------------|-------------------------------------------------|
| ate.def      | Contains ATE default values.                    |
| /usr/lib/dir | Contains the default dialing directory listing. |

## DOMAIN Cache File Format for TCP/IP

### Purpose

Defines the root name server or servers for a DOMAIN name server host.

### Description

The **cache** file is one of the DOMAIN data files and contains the addresses of the servers that are authoritative name servers for the root domain of the network. The name of this file is defined in the **named** boot file. If the host serves more than one domain, the cache file should contain an entry for the authoritative name server for each domain.

All entries in this file must be in Standard Resource Record Format. Valid resource records in this file are:

- Name Server (NS)
- Address (A)

Except for comments (starting with a ; [semicolon] and continuing to the end of the line), the resource records in the data files generally follow the format of the resource records that the **named** daemon returns in response to queries from resolver routines.

## Examples

The following examples show the various ways to use the cache data file. This example is valid for any name server or either of the two networks.

Network abc consists of:

- gobi.abc, the primary name server for the abc network, 192.9.201.2
- mojave.abc, a host machine, 192.9.201.6
- sandy.abc, secondary name server for the abc network and gateway between abc and xyz, 192.9.201.3

Network xyz consists of:

- kalahari.xyz, primary name server for the xyz network, 160.9.201.4
- lopnor.xyz, a host machine, 160.9.201.5
- sahara.xyz, a host machine and cache-only name server for the xyz network, 160.9.201.13

- sandy.xyz, a secondary name server for the xyz network and gateway between abc and xyz, 160.9.201.3

**Note:** sandy, a gateway host, is on both networks and also serves as secondary name server for both.

The following are sample entries in a DOMAIN cache file on any of the name servers in either of the domains:

```
;;
;cache file for all nameservers in both domains
;;
; root name servers.
abc IN NS gobi.abc.
xyz IN NS kalahari.xyz.
gobi.abc. 3600000 IN A 192.9.201.2
kalahari.xyz. 3600000 IN A 160.9.201.4
```

## Files

| Item                          | Description                                                                  |
|-------------------------------|------------------------------------------------------------------------------|
| /etc/named.conf               | Defines how the <b>named</b> daemon initializes the DOMAIN name server file. |

named command

## DOMAIN Data File Format for TCP/IP

### Purpose

Stores name resolution information for the **named** daemon.

### Description

The host's data file is one of the DOMAIN data files and contains name-to-address resolution mapping information for all machines in the name server's zone of authority. The name of the host's data file is specified in the **named** boot file. This file should exist only on name servers that are designated as *primary* for a domain. There may be more than one host's data file per primary name server.

All entries in this file must be in Standard Resource Record Format. Valid resource records in this file are:

- Start of Authority (SOA)
- Name Server (NS)
- Address (A)
- Mailbox (MB)
- Mail Exchanger (MX)
- Mail Group (MG)
- Mail Rename (MR)
- Canonical Name (CNAME)
- Well Known Services (WKS)

- Host Information (HINFO)

Except for comments (starting with a ; (semicolon) and continuing to the end of the line), the resource records in the data files generally follow the format of the resource records that the **named** daemon returns in response to queries from resolver routines.

Two **awk** scripts, **addrs.awk** and **hosts.awk**, are provided in the **/usr/samples/tcpip** directory to assist you in converting your existing **/etc/hosts** file to DOMAIN data files. The **awk** scripts also contain instructions for their use. Refer to these files for more information on the conversion.

## Examples

The following examples show the various ways to use the DOMAIN host's data file. In these examples, two networks are represented: abc and xyz.

Network abc consists of:

- gobi.abc, the primary name server for the abc network, 192.9.201.2
- mojave.abc, a host machine, 192.9.201.6
- sandy.abc, secondary name server for the abc network and gateway between abc and xyz, 192.9.201.3

Network xyz consists of:

- kalahari.xyz, primary name server for the xyz network, 160.9.201.4
- lopnor.xyz, a host machine, 160.9.201.5
- sahara.xyz, a host machine and cache-only name server for the xyz network, 160.9.201.13
- sandy.xyz, a secondary name server for the xyz network and gateway between abc and xyz, 160.9.201.3

**Note:** Host sandy, a gateway host, is on both networks and also serves as secondary name server for both.

1. The primary host data file for network abc, stored on host gobi.abc, contains the following entries:

```

;
;primary host data file for abc - gobi.abc
;

## DOMAIN Local Data File Format for TCP/IP

### Purpose

Defines the local loopback information for the **named** daemon on the name server host.

### Description

The local data file is one of the DOMAIN data files and contains local loopback information for the name-server host. The name of the DOMAIN local data files is specified in the **named** boot file.

All entries in this file must be in Standard Resource Record Format. Valid resource records in the local data file are:

- Start of Authority (SOA)
- Name Server (NS)
- Pointer (PTR)

The records in the DOMAIN data files are called resource records. Except for comments (starting with a ; (semicolon) and continuing to the end of the line), the resource records in the data files generally follow the format of the resource records that the **named** daemon returns in response to queries from resolver routines.

### Examples

The following examples show the various ways to use the DOMAIN local data file. In these examples, two networks are represented: abc and xyz.

Network abc consists of:

- gobi.abc, the primary name server for the abc network, 192.9.201.2
- mojave.abc, a host machine, 192.9.201.6
- sandy.abc, secondary name server for the abc network and gateway between abc and xyz, 192.9.201.3.

Network xyz consists of:

- kalahari.xyz, primary name server for the xyz network, 160.9.201.4
- lopnor.xyz, a host machine, 160.9.201.5

- sahara.xyz, a host machine and cache-only name server for the xyz network, 160.9.201.13
- sandy.xyz, a secondary name server for the xyz network and gateway between abc and xyz, 160.9.201.3

**Note:** Host sandy, a gateway host, is on both networks and also serves as secondary name server for both.

1. The **named.abclocal** file stored on gobi.abc contains the following entries:

```
;
;primary reverse file for local 127 network
;
@ IN SOA gobi.abc. root.gobi.abc.
(
 1.1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
IN NS gobi.abc.
1 IN PTR localhost.
```

2. The **named.xyzlocal** file stored on kalahari.xyz contains the following entries:

```
;
;primary reverse file for local 127 network
;
@ IN SOA kalahari.xyz. root.kalahari.xyz.
(
 1.1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
IN NS kalahari.xyz.
1 IN PTR localhost.
```

3. The **named.seclocal** file stored on sandy contains the following entries:

```
;
;primary reverse file for local 127 network
;
@ IN SOA sandy.abc. root.sandy.abc.
(
 1.1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
IN NS sandy.abc.
1 IN PTR localhost.
```

4. The **named.calocal** file stored on sahara.xyz contains the following entries:

```
;
;primary reverse file for local 127 network
;
@ IN SOA sahara.xyz. root.sahara.xyz.
(
 1.1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
IN NS sahara.xyz.
1 IN PTR localhost.
```

## DOMAIN Reverse Data File Format for TCP/IP

### Purpose

Stores reverse name resolution information for the **named** daemon.

### Description

The Reverse Data file is one of the DOMAIN data files and contains address to name resolution mapping information for all machines in the name server's zone of authority. The name of the reverse hosts data file is specified in the **named** boot file. There may be more than one reverse hosts data file per primary name server.

All entries in this file must be in Standard Resource Record Format. Valid resource records in this file are:

- Start of Authority (SOA)
- Name Server (NS)
- Pointer (PTR)

Except for comments (starting with a ; (semicolon) and continuing to the end of the line), the resource records in the data files generally follow the format of the resource records that the **named** daemon returns in response to queries from resolver routines.

Two **awk** scripts, **addrs.awk** and **hosts.awk**, are provided in the **/usr/samples/tcpip** directory to assist you in converting your existing **/etc/hosts** file to **named** data files. The **awk** scripts also contain instructions for their use. Refer to these files for more information on the conversion.

### Examples

The following examples show the various ways to use the DOMAIN Reverse Data file. In these examples, two networks are represented: abc and xyz.

Network abc consists of:

- gobi.abc, the primary name server for the abc network, 192.9.201.2
- mojave.abc, a host machine, 192.9.201.6
- sandy.abc, secondary name server for the abc network and gateway between abc and xyz, 192.9.201.3

Network xyz consists of:

- kalahari.xyz, primary name server for the xyz network, 160.9.201.4
- lopnor.xyz, a host machine and cache-only name server for the xyz network, 160.9.201.5
- sahara.xyz, a host machine, 160.9.201.13

- sandy.xyz, a secondary name server for the xyz network and gateway between abc and xyz, 160.9.201.3

**Note:** Host sandy, a gateway host, is on both networks and also serves as secondary name server for both.

1. The reverse data file for gobi.abc, primary name server for network abc, contains these entries:

```
;
;primary reverse host data file for abc - gobi.abc
;
@ IN SOA gobi.abc. root.gobi.abc. (
 1:1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
;nameservers for abc
;other nameservers
4.201.9.160.in-addr.arpa IN PTR kalahari.xyz.
;define all hosts in abc
2 IN PTR gobi.abc.
3 IN PTR sandy.abc.
6 IN PTR mojave.abc.
```

2. The reverse data file for kalahari.xyz, primary name server for network xyz, contains these entries:

```
;
;primary reverse host data file for xyz - kalahari.xyz
;
@ IN SOA kalahari.xyz. root.kalahari.xyz. (
 1:1 ;serial
 3600 ;refresh
 600 ;retry
 3600000;expire
 86400 ;minimum
)
;nameservers for xyz
;other nameservers
2.201.9.192.in-addr.arpa IN PTR gobi.abc.
;define all hosts in xyz
4.201 IN PTR kalahari.xyz.
13.201 IN PTR sahara.xyz.
5.201 IN PTR lopnor.xyz.
3.201 IN PTR sandy.xyz.
```

## eqnchar File Format

### Purpose

Contains special character definitions for the **eqn** and **neqn** commands.

### Description

The **/usr/share/lib/pub/eqnchar** file contains the following **troff** and **nroff** command character definitions not ordinarily available on a phototypesetter or printer. These definitions are primarily intended for use with the **eqn** and **neqn** commands. The **eqnchar** file format contains definitions for the characters shown in the following character definition list.

|          |                               |             |                   |         |                 |
|----------|-------------------------------|-------------|-------------------|---------|-----------------|
| ciplus   | $\oplus$                      | $\parallel$ | $\parallel$       | square  | $\square$       |
| citimes  | $\otimes$                     | langle      | $\langle$         | circle  | $\circ$         |
| wig      | $\sim$                        | rangle      | $\rangle$         | blot    | $\blacksquare$  |
| -wig     | $\approx$                     | hbar        | $\hbar$           | bullet  | $\bullet$       |
| >wig     | $\approx\backslash$           | ppd         | $\perp$           | prop    | $\triangleleft$ |
| <wig     | $\approx\backslash\backslash$ | <>          | $\leftrightarrow$ | empty   | $\emptyset$     |
| -wig     | $\cong$                       | <>          | $\Leftrightarrow$ | member  | $\in$           |
| star     | *                             | <           | $\nmid$           | nonmem  | $\notin$        |
| bigstar  | *                             | >           | $\ntriangleright$ | cup     | $\cup$          |
| -dot     | $\doteq$                      | ang         | $\angle$          | cap     | $\cap$          |
| orsign   | $\vee$                        | rang        | $\llcorner$       | incl    | $\sqsubset$     |
| andsign  | $\wedge$                      | 3dot        | $\vdots$          | subset  | $\sqsubseteq$   |
| -del     | $\Delta$                      | thf         | $\therefore$      | supset  | $\sqsupset$     |
| oppA     | $\forall$                     | quarter     | $\frac{1}{4}$     | !subset | $\sqsubset\neg$ |
| oppE     | $\exists$                     | 3quarter    | $\frac{3}{4}$     | !supset | $\sqsupset\neg$ |
| angstrom | $\text{\AA}$                  | degree      | $\circ$           | scrL    | $\ell$          |

This illustration shows symbols commonly used in equations.

The `/usr/share/lib/pub/cateqnchar` file is device-independent and should produce output that looks reasonable on any device supported by the `troff` command. You can link the `/usr/share/lib/pub/eqnchar` file to the `/usr/share/lib/pub/cateqnchar` file.

The `eqnchar` file format can be used with either the `eqn` or `neqn` command and then piped to the `troff` or `nroff` command. For example:

```
eqn /usr/share/lib/pub/eqnchar [Flag...][—][File...]|troff [Flag...]
eqn /usr/share/lib/pub/cateqnchar [Flag...][—][File...]|troff [Flag...]
neqn /usr/share/lib/pub/eqnchar [Flag...][—][File...]|nroff [Flag...]
```

## /etc/ftpd.cnf File Format for TCP/IP

### Purpose

Specifies the configuration parameters of the `ftpd` daemon to start a transport layer security (TLS) session.

## Description

The **/etc/ftpd.cnf** file is an ASCII file that contains configuration parameters of the **ftpd** daemon to set up a TLS session upon receiving a TLS request from an **ftp** client.

The **/etc/ftpd.cnf** file contains the following entries separated by spaces, tabs, or new lines:

| Item                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CRL_PATH</b>                | Specifies the path to the certificate-revocation-list file in privacy enhanced mail (PEM) format. If the <b>CRL_PATH</b> entry is specified, the digital certificate that the client provides is verified against the certificate revocation list. If the <b>ftp</b> client is not using a digital certificate, the connection fails. If the client provides a digital certificate, but the certificate has been revoked, the TLS session fails. If this parameter is not specified, the client does not have to provide a digital certificate. |
| <b>CA_PATH</b>                 | Specifies the path to the trusted certificate-authority file in PEM format. If the <b>CA_PATH</b> entry is specified, the client certificate is verified against the certificate authority. If the client does not provide a digital certificate, the connection fails. If the client provides a digital certificate, but the certificate authority has not signed the certificate, the TLS session fails. If this parameter is not specified, the client does not have to provide a digital certificate.                                       |
| <b>CIPHER_LIST</b>             | Specifies the list that is used during the TLS session. If it is not specified, a default cipher list is used.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>DEPTH</b>                   | Verify the certificate that the <b>ftp</b> client provides in the digital certificate hierarchy, if the <b>CA_PATH</b> configuration parameter has been specified. If the <b>DEPTH</b> entry is not provided, a default value of 9 is used.                                                                                                                                                                                                                                                                                                     |
| <b>CERTIFICATE</b>             | Specifies the path to a valid chain of digital-certificates files in PEM format. This entry must be specified to start a TLS session. If this entry is not specified, the <b>ftpd</b> server rejects all TLS requests.                                                                                                                                                                                                                                                                                                                          |
| <b>CERTIFICATE_PRIVATE_KEY</b> | Specifies the path to the certificate private key in PEM format. This entry must be specified to start a TLS session. If this entry is not specified, the <b>ftpd</b> server rejects all TLS requests.                                                                                                                                                                                                                                                                                                                                          |
| <b>DH_PARAMETERS_DIR</b>       | Specifies the path to a directory containing Diffie-Helman parameters in PEM format. More than one file can be included in this directory. The <b>ftpd</b> daemon searches for the appropriate parameter.                                                                                                                                                                                                                                                                                                                                       |

## Examples

The following is an example of an entry in the **/etc/ftpd.cnf** file:

```
CRL_PATH /crl.pem
CA_PATH /ca.pem
CIPHER_LIST ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH
DEPTH 2
CERTIFICATE /cert.pem
CERTIFICATE_PRIVATE_KEY /privatekey.pem
DH_PARAMETERS_DIR /DH_DIR
```

## Files

### Related information:

**ftpd** command

## **/etc/security/rtc/rtcd.conf** file format for real-time compliance

### Purpose

Contains configuration information for the **rtcd** daemon.

## Description

The **/etc/security/rtc/rtcd.conf** file is the configuration file for the **rtcd** daemon. This file is updated by the **mkrtc** command when configuring the real-time compliance subsystem. You can modify the **/etc/security/rtc/rtcd.conf** file by using a file editor. If the real-time compliance subsystem is configured and running, any change to this file becomes effective immediately and it is not necessary to restart the **rtcd** daemon.

Each line is of the form:

attribute: value

The **/etc/security/rtc/rtcd.conf** file has the following attributes:

- - alertStyle**
    - Specifies the alert style. The valid values follows:
      - once** Alert once for the same set of compliance violations. This is default value.
      - event** Alert once for the same set of compliance violations, but keep alerting for each file modification event.
  - |
    - always**
      - Alert compliance violations and file modification on each file change event.
  - - alertMsgSize**
      - Specifies the alert message size. The limited size is suitable for email addresses that are directed at the smartphone SMS messaging. The valid values follows:
        - verbose**
          - Provides the entire message. This is the default value.
        - limited**
          - Limits the size of the alert message to the first violation and the first event. If there are more than one violations or events, it is indicated in the message.
    - - debug** Specifies whether to turn on debug messages on. The valid values are **on** and **off**. The default value is **off**.
    - - email** Specifies the email address to which the alerts will be sent. It allows multiple *email:<email address>* pairs, each pair on a separate line.
    - - infolevel**
        - Specifies the information level of file modification events. The valid values are **1**, **2**, and **3**. The default value is 1. A higher value indicates more details.
    - - emailSubject**
        - Specifies the subject line that is used for the email alert.
    - - minCheckTime**
        - Specifies the minimum amount of time between compliance verifications. This setting ensures regular compliance check without file modification triggers, to check whether the files created by user have compliance implications. For example, the **.rhost** file in the home directory of a

user can be checked by using this setting. The default minimum time is 30 minutes. If this value is set to 0, the compliance check is never done.

- **snmptrap**

Specifies the parameters for the **snmptrap** notifications. See the **snmptrap** command for setting the parameters for the **snmptrap** notifications. To enable the **snmptrap** alert, set it to **yes**. To disable the **snmptrap** alert, set it to **no**. The following parameters are set to disable the **snmptrap** alert:

```
snmptrap_enable: no
snmptrap_host:localhost
snmptrap_community:myCommunity
snmptrap_oid:myOID
```

## Security

The **/etc/security/rtc/rtcd.conf** file is owned by the root user and the security group. The **/etc/security/rtc/rtcd.conf** file grants read (r) and write (w) access only to the root user.

## Examples

The following list is an example of an entry in the **/etc/security/rtc/rtcd.conf** file:

- Lists the email addresses to send alerts to.

```
email: foo@abc.com
email: dummy@abc.com
```

- Specifies the subject of the email alert:

```
emailSubject: Compliance Alert
```

- Specifies the information level of file modifications:

```
infolevel: 1
```

- Specifies the alertStyle attribute of the email alert:

```
alertStyle: once
```

- Specifies whether to turn on debug.

```
debug: on
```

## /etc/security/rtc/rtcd\_policy.conf file format for real-time compliance Purpose

Defines a list of files and the associated events to be monitored by the real-time compliance subsystem.

### Description

The **/etc/security/rtc/rtcd\_policy.conf** file contains a list of files and the associated events to be monitored by the real-time compliance subsystem. The file is a stanza file with each stanza name being a file name followed by a colon.

The attributes are in the following form:

```
attribute: value
```

Any change to this file becomes effective immediately, it is not required to restart the **rtcd** daemon.

Users can add or remove files from the **/etc/security/rtc/rtcd\_policy.conf** file using the **chsec** command. It is recommended to stop the real-time compliance subsystem if you are adding large number of files using the **chsec** command to avoid potential alerts from these additions.

The **/etc/security/rtc/rtcd\_policy.conf** file has the following attribute:

•

#### **eventtype**

Defines the even type to be monitored. It can be one or both of the following values, separated by a comma:

#### **ModFile**

File content modifications.

#### **modFileAttr**

File attribute modifications.

## **Security**

The **/etc/security/rtc/rtcd\_policy.conf** file is owned by the root user and the security group. It grants read (r) and write (w) access only to the root user.

## **Examples**

The following are examples of an entry in the **/etc/security/rtc/rtcd.conf** file:

```
/etc/inetd.conf:
 eventtype = modFile
/etc/security/audit/config:
 eventtype = modFile,modFileAttr
/usr/bin/chsec:
 eventtype = modFileAttr
```

## **/etc/ftpd.cnf File Format for TCP/IP**

### **Purpose**

Specifies the configuration parameters of the **ftpd** daemon to start a transport layer security (TLS) session.

### **Description**

The **/etc/ftpd.cnf** file is an ASCII file that contains configuration parameters of the **ftpd** daemon to set up a TLS session upon receiving a TLS request from an **ftp** client.

The **/etc/ftpd.cnf** file contains the following entries separated by spaces, tabs, or new lines:

| Item        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CRL_PATH    | Specifies the path to the certificate-revocation-list file in privacy enhanced mail (PEM) format. If the <b>CRL_PATH</b> entry is specified, the digital certificate that the client provides is verified against the certificate revocation list. If the <b>ftp</b> client is not using a digital certificate, the connection fails. If the client provides a digital certificate, but the certificate has been revoked, the TLS session fails. If this parameter is not specified, the client does not have to provide a digital certificate. |
| CA_PATH     | Specifies the path to the trusted certificate-authority file in PEM format. If the <b>CA_PATH</b> entry is specified, the client certificate is verified against the certificate authority. If the client does not provide a digital certificate, the connection fails. If the client provides a digital certificate, but the certificate authority has not signed the certificate, the TLS session fails. If this parameter is not specified, the client does not have to provide a digital certificate.                                       |
| CIPHER_LIST | Specifies the list that is used during the TLS session. If it is not specified, a default cipher list is used.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DEPTH       | Verify the certificate that the <b>ftp</b> client provides in the digital certificate hierarchy, if the <b>CA_PATH</b> configuration parameter has been specified. If the <b>DEPTH</b> entry is not provided, a default value of 9 is used.                                                                                                                                                                                                                                                                                                     |

| Item                           | Description                                                                                                                                                                                                            |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CERTIFICATE</b>             | Specifies the path to a valid chain of digital-certificates files in PEM format. This entry must be specified to start a TLS session. If this entry is not specified, the <b>ftpd</b> server rejects all TLS requests. |
| <b>CERTIFICATE_PRIVATE_KEY</b> | Specifies the path to the certificate private key in PEM format. This entry must be specified to start a TLS session. If this entry is not specified, the <b>ftpd</b> server rejects all TLS requests.                 |
| <b>DH_PARAMETERS_DIR</b>       | Specifies the path to a directory containing Diffie-Helman parameters in PEM format. More than one file can be included in this directory. The <b>ftpd</b> daemon searches for the appropriate parameter.              |

## Examples

The following is an example of an entry in the **/etc/ftpd.cnf** file:

```
CRL_PATH /crl.pem
CA_PATH /ca.pem
CIPHER_LIST ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH
DEPTH 2
CERTIFICATE /cert.pem
CERTIFICATE_PRIVATE_KEY /privatekey.pem
DH_PARAMETERS_DIR /DH_DIR
```

## Files

| Item                               | Description                 |
|------------------------------------|-----------------------------|
| <b>/usr/samples/tcpip/ftpd.cnf</b> | Sample <b>ftpd.cnf</b> file |

### Related information:

**ftpd** command

## /etc/tnc\_config File

### Purpose

Stores the information on the various Integrity Measurement Collector (IMC) and Integrity Measurement Verifier (IMV) modules configured on the system.

### Description

The **/etc/tnc\_config** file is a Trusted Network Connect (TNC) standard configuration file. It stores the information on the various IMC and IMV modules configured on the system.

### Format

#### ModuleType

Specifies type of the module, whether it is IMC or IMV.

#### Comment

Specifies the comment on the module.

#### ModulePath

Specifies the path of the module shared object.

The TNC server and client daemons use this configuration to load the various modules configured on the system. The modules should be standard shared library archives, and the *dlopen()* calls is used to read the symbols.

## Examples

```
IMC "FILESETS" /usr/lib/security/tnc/imc_filesets.a(shr.o)
```

## .ftpcnf File Format for TCP/IP

### Purpose

Specifies configuration parameters of the **ftp** command to start a transport layer security (TLS) session.

### Description

The **\$HOME/.ftpcnf** file is an ASCII file that contains configuration parameters of the **ftp** command to set up a TLS session.

The **\$HOME/.ftpcnf** file contains the following entries separated by spaces, tabs, or new lines:

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CRL_PATH                | Specifies the path to the certificate-revocation-list file in privacy enhanced mail (PEM) format. If you specify the <b>CRL_PATH</b> entry, the digital certificate that the server provides is verified against the certificate revocation list. If the certificate has been revoked, the TLS session fails. If you do not specify the <b>CRL_PATH</b> entry, the digital certificate is not verified against a certificate revocation list.                           |
| CA_PATH                 | Specify the path to the trusted certificate-authority file in PEM format. If you specify the <b>CA_PATH</b> entry, the server certificate is verified against the certificate authority. If the certificate authority has not signed the digital certificate that the server provides, the TLS session fails. If you do not specify the <b>CA_PATH</b> entry, the digital certificate that the server provides is not verified against a trusted certificate authority. |
| CIPHER_LIST             | Specifies the list that is used during the TLS session. If you do not specify the <b>CIPHER_LIST</b> entry, a default cipher list is used.                                                                                                                                                                                                                                                                                                                              |
| DEPHT                   | Verifies the certificate that the <b>ftpd</b> server provides in the digital certificate hierarchy, if you have specified the <b>CA_PATH</b> configuration parameter. If you do not provide the <b>DEPHT</b> entry, a default value of 9 is used.                                                                                                                                                                                                                       |
| CERTIFICATE             | Specifies the path to a valid chain of digital certificates in PEM format. If you specify the <b>CERTIFICATE</b> entry, the <b>ftp</b> command uses the digital certificate chain during the TLS session.                                                                                                                                                                                                                                                               |
| CERTIFICATE_PRIVATE_KEY | Specifies the path to the private key corresponding to the certificate in PEM format.                                                                                                                                                                                                                                                                                                                                                                                   |

### Examples

The following is an example of an entry in the **.ftpcnf** file:

```
CRL_PATH /home/USERNAME/crl.pem
CA_PATH /home/USERNAME/ca.pem
CIPHER_LIST ALL:!ADH:!LOW:!EXP:!MD5:@STRENGTH
DEPHT 2
CERTIFICATE /home/USERNAME/cert.pem
CERTIFICATE_PRIVATE_KEY /home/USERNAME/privatekey.pem
```

### Files

| Item                       | Description          |
|----------------------------|----------------------|
| /usr/samples/tcpip/.ftpcnf | Sample .ftpcnf file. |

### Related information:

**ftp** command

## ftpusers File Format for TCP/IP

### Purpose

Specifies local user names that cannot be used by remote FTP clients.

## Description

The **/etc/ftpusers** file contains a list of local user names that the **ftpd** server does *not* allow remote File Transfer Protocol (FTP) clients to use. The format of the **ftpusers** file is a simple list of user names that also appear in the **/etc/passwd** file.

Entries to this file can be made using the System Management Interface Tool (SMIT) or the **ruser** command.

## Examples

The following are sample entries in an **ftpusers** file:

```
root
guest
ftp
joan
UUCP
```

## Files

| Item               | Description                               |
|--------------------|-------------------------------------------|
| <b>/etc/passwd</b> | Contains user authentication information. |

## gated.conf File Format for TCP/IP

### Purpose

Contains configuration information for the **gated** daemon.

## Description

The **/etc/gated.conf** file contains configuration information for the **gated** daemon. The file contains a sequence of statements. Statements are composed of tokens separated by white space. You can create white space using any combination of blanks, tabs, and new lines. The **gated.conf** file supports several statements:

| Item                           | Description                                                                                                                                                                                                |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>%directory</b> (directive)  | Sets the directory for include files.                                                                                                                                                                      |
| <b>%include</b> (directive)    | Includes a file into <b>gated.conf</b> .                                                                                                                                                                   |
| <b>traceoptions</b> (trace)    | Specifies which events are traced.                                                                                                                                                                         |
| <b>options</b> (definition)    | Defines <b>gated.conf</b> options.                                                                                                                                                                         |
| <b>interfaces</b> (definition) | Defines <b>gated.conf</b> interfaces.                                                                                                                                                                      |
| <b>autonomoussystem</b>        | Defines the AS number.                                                                                                                                                                                     |
| <b>routerid</b> (definition)   | Defines the originating router (BGP, OSPF).                                                                                                                                                                |
| <b>martians</b> (definition)   | Defines invalid destination addresses.                                                                                                                                                                     |
| <b>rip</b> (protocol)          | Enables RIP protocol.                                                                                                                                                                                      |
| <b>ripng</b>                   | Enables or disables RIPNG. If the RIPNG statement is not specified, the default is <b>ripng on</b> ; The options are the same for RIPNG as they are for RIP, but all the addresses will be IPv6 addresses. |
| <b>hello</b> (protocol)        | Enables HELLO protocol.                                                                                                                                                                                    |
| <b>isis</b> (protocol)         | Enables ISIS protocol.                                                                                                                                                                                     |
| <b>ospf</b> (protocol)         | Enables OSPF protocol.                                                                                                                                                                                     |
| <b>EGP</b> (protocol)          | Enables EGP protocol.                                                                                                                                                                                      |

| Item                       | Description                                                                          |
|----------------------------|--------------------------------------------------------------------------------------|
| <b>bgp</b> (protocol)      | Enables BGP protocol.                                                                |
| <b>bgp4+</b>               | The options are the same as <b>bgp</b> but all the addresses will be IPv6 addresses. |
| <b>icmp</b> (protocol)     | Configures the processing of general ICMP packets.                                   |
| <b>snmp</b> (protocol)     | Enables reporting to SNMP.                                                           |
| <b>static</b> (static)     | Defines static routes.                                                               |
| <b>import</b> (control)    | Defines which routes to import.                                                      |
| <b>export</b> (control)    | Defines which routes to export.                                                      |
| <b>aggregate</b> (control) | Defines which routes to aggregate.                                                   |
| <b>generate</b> (control)  | Defines which routes to generate.                                                    |

## Directive Statements

Directive statements provide direction to the **gated.conf** configuration language parser about included files and the directories in which these files reside. Directive statements are immediately acted upon by the parser. Other statements terminate with a semi-colon (;), but directive statements terminate with a newline. The two directive statements are:

| Item                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>%directory "directory"</b> | Defines the directory where the include files are stored. When it is used, <b>gated.conf</b> looks in the directory identified by pathname for any included files that do not have a fully qualified filename, that is, do not begin with "/". This statement does not actually change the current directory, it just specifies the prefix applied to included file names.                                                                                                                                                                    |
| <b>%include "filename"</b>    | Identifies an include file. The contents of the file are <i>included</i> in the <b>gated.conf</b> file at the point in the <b>gated.conf</b> file where the <b>%include</b> directive is encountered. If the filename is not fully qualified, that is, does not begin with "/", it is considered to be relative to the directory defined in the <b>%directory</b> directive. The <b>%include</b> directive statement causes the specified file to be parsed completely before resuming with this file. Nesting up to ten levels is supported. |

In a complex environment, segmenting a large configuration into smaller more easily understood segments might be helpful, but one of the great advantages of **gated.conf** is that it combines the configuration of several different routing protocols into a single file. Segmenting a small file unnecessarily complicates routing configurations.

## Trace Statements

Trace statements control tracing options. **gated.conf**'s tracing options may be configured at many levels. Tracing options include the file specifications, control options, and global and protocol specific tracing options. Unless overridden, tracing options from the next higher level are inherited by lower levels. For example, BGP peer tracing options are inherited from BGP group tracing options, which are inherited from global BGP tracing options, which are inherited from global **gated.conf** tracing options. At each level, tracing specifications override the inherited options.

### Global tracing options

There are two types of global options, those that only affect global operations, and those that have potential significance to protocols.

#### Global significance only

The trace flags that only have global significance are:

| Item           | Description                                                                                                                                                                                                                                   |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>parse</b>   | Traces the lexical analyzer and parser. Mostly used by <b>gated.conf</b> developers for debugging.                                                                                                                                            |
| <b>adv</b>     | Traces the allocation of and freeing of policy blocks. Mostly used by the <b>gated.conf</b> developers for debugging.                                                                                                                         |
| <b>symbols</b> | Used to trace symbols read from the kernel at startup. The only useful way to specify this level of tracing is via the <b>-t</b> option on the command line since the symbols are read from the kernel before parsing the configuration file. |
| <b>iflist</b>  | Used to trace the reading of the kernel interface list. It is useful to specify this with the <b>-t</b> option on the command line since the first interface scan is done before reading the configuration file.                              |

## Protocol significance

The options flags that have potential significance to protocols are:

| Item           | Description                                                                                    |
|----------------|------------------------------------------------------------------------------------------------|
| <b>all</b>     | Turn on all of the following.                                                                  |
| <b>general</b> | Shorthand notation for specifying both normal and route.                                       |
| <b>state</b>   | Trace state machine transitions in the protocols.                                              |
| <b>normal</b>  | Trace normal protocols occurrences. Abnormal protocol occurrences are always traced.           |
| <b>policy</b>  | Trace application of protocol and user-specified policy to routes being imported and exported. |
| <b>task</b>    | Trace system interface and processing associated with this protocol or peer.                   |
| <b>timer</b>   | Trace timer usage by this protocol or peer.                                                    |
| <b>route</b>   | Trace routing table changes for routes installed by this protocol or peer.                     |

### Note:

1. Not all of the above options apply to all of the protocols. In some cases, their use does not make sense (for instance, RIP does not have a state machine) and in some instances the requested tracing has not been implemented (such as RIP support of the policy option).
2. It is not currently possible to specify packet tracing from the command line. This is because a global option for packet tracing would potentially create too much output.

When protocols inherit their tracing options from the global tracing options, tracing levels that don't make sense (such as parse, adv and packet tracing options) are masked out.

Global tracing statements have an immediate effect, especially parsing options that affect the parsing of the configuration file. Tracing values inherited by protocols specified in the configuration file are initially inherited from the global options in effect as they are parsed, unless they are overridden by more specific options. After the configuration file is read, tracing options that were not explicitly specified are inherited from the global options in effect at the end of the configuration file.

## Packet tracing

Tracing of packets is very flexible. For any given protocol, there are one or more options for tracing packets. All protocols allow use of the **packets** keyword that allows for tracing all packets sent and received by the protocol. Most protocols have other options for limiting tracing to a useful subset of packet types. These tracing options can be further controlled with the following modifiers:

**detail** The detail must be specified before send or recv. Normally packets are traced in a terse form of one or two lines. When detail is specified, a more verbose format is used to provide further detail on the contents of the packet.

### send

**recv** These options limit the tracing to packets sent or received. Without these options both sent and received packets will be traced.

**Note:** Detail, if specified, must be before send or recv. If a protocol allows for several different types of packet tracing, modifiers may be applied to each individual type. But be aware that within one tracing specification the trace flags are summed up, so specifying detail packets will turn on full tracing for all packets.

## Traceoptions syntax

```
traceoptions ["trace_file" [replace] [size size[k|m] files files]]
[control_options] trace_options [except trace_options] ;
traceoptions none ;
```

| Item                              | Description                                                                                                                                                                                                                                                        |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>trace_file</i>                 | Specifies the file to receive tracing information. If this file name does not begin with a slash (/), the directory where <b>gated</b> was started is prepended to the name.                                                                                       |
| <b>replace</b>                    | Indicates tracing should start by replacing an existing file. The default is to append to an existing file.                                                                                                                                                        |
| <b>size size[k m] files files</b> | Limits the maximum size of the trace file to the specified size (minimum 10k). When the trace file reaches the specified size, it is renamed to <i>file.0</i> , then <i>file.1</i> , <i>file.2</i> up to the maximum number of files (minimum specification is 2). |
| <i>control_options</i>            | Specifies options that control the appearance of tracing. Valid values are:                                                                                                                                                                                        |
| <b>nostamp</b>                    | Specifies that a timestamp should not be prepended to all trace lines.                                                                                                                                                                                             |
| <b>except trace_options</b>       | Used to enable a broad class of tracing and then disable more specific options.                                                                                                                                                                                    |
| <b>none</b>                       | Specifies that all tracing should be turned off for this protocol or peer.                                                                                                                                                                                         |

## Options Statements

Options statements allow specification of some global options. If used, options must appear before any other type of configuration statement in the **gated.conf** file.

The options statement syntax is:

```
options
 [nosend]
 [noresolv]
[gendefault [preference preference] [gateway gateway]]
 [syslog [upto] log_level]
[mark time]
;
```

The options list can contain one or more of the following options:

| Item                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gendefault [preference preference ] [gateway gateway]</b> | When gendefault is enabled when a BGP or EGP neighbor is up, it causes the creation of a default route with the special protocol default. This can be disabled per BGP/EGP group with the nogendefault option. By default, this route has a preference of 20. This route is normally not installed in the kernel forwarding table, it is only present so it can be announced to other protocols. If a gateway is specified, the default route will be installed in the kernel forwarding table with a next hop of the listed gateway.<br><b>Note:</b> The use of the more general generate default option is preferred to the use of this gendefault option. See the section on Route Aggregation for more information on the generate statement. |

| Item                           | Description                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nosend</b>                  | Do not send any packets. This option makes it possible to run <b>gated.conf</b> on a live network to test protocol interactions without actually participating in the routing protocols. The packet traces in the <b>gated.conf</b> log can be examined to verify that <b>gated.conf</b> is functioning properly. This is most useful for RIP and HELLO. |
| <b>noresolv</b>                | By default, <b>gated.conf</b> will try to resolve symbolic names into IP addresses; this option will prevent that.                                                                                                                                                                                                                                       |
| <b>syslog [upto] log_level</b> | Controls the amount of data <b>gated.conf</b> logs via syslog.                                                                                                                                                                                                                                                                                           |
| <b>mark time</b>               | Specifying this option causes <b>gated</b> to output a message to the trace log at the specified interval. This can be used as one method of determining if <b>gated</b> is still running.                                                                                                                                                               |

## Interface Statement

### Interface Syntax

```

interfaces {
 options
 [strictinterfaces]
 [scaninterval time]
 ;
 interface interface_list
 [preference preference]
 [down preference preference]
 [passive]
 [simplex]
 [reject]
 [blackhole]
 ;
 define address
 [broadcast address] | [pointtopoint address]
 [netmask mask]
 [multicast]
 ;
} ;

```

An interface is the connection between a router and one of its attached networks. A physical interface may be specified by interface name, by IP address, or by domain name, (unless the network is an unnumbered point-to-point network.) Multiple levels of reference in the configuration language allow identification of interfaces using wildcard, interface type name, or delete word addresses. The *interface\_list* is a list of one or more interface names including wildcard names (names without a number) and names that may specify more than one interface or address, or the token *all* for all interfaces.

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>interface_list</i> | Sets interface options on the specified interfaces. An interface list is <b>all</b> or a list of interface names domain names, or numeric addresses. Options available on this statement are:                                                                                                                                                                                                                                                                                                                                                                                     |
|                                        | <b>preference</b> <i>preference</i><br>Sets the preference for routes to this interface when it is up and appears to be functioning properly. The default preference is 0.                                                                                                                                                                                                                                                                                                                                                                                                        |
|                                        | <b>down preference</b> <i>preference</i><br>Sets the preference for routes to this interface when the <b>gated</b> daemon does not believe it to be functioning properly, but the kernel does not indicate it is down. The default value is 120.                                                                                                                                                                                                                                                                                                                                  |
|                                        | <b>passive</b> Prevents the <b>gated</b> daemon from changing the preference of the route to this interface if it is not believed to be functioning properly due to lack of received routing information. The <b>gated</b> daemon will only perform this check if the interface is actively participating in a routing protocol.                                                                                                                                                                                                                                                  |
| <b>define</b> <i>address</i>           | Defines interfaces that might not be present when the <b>gated</b> daemon is started so they may be referenced in the configuration file when <b>strictinterfaces</b> is defined.<br>Possible define keywords are:                                                                                                                                                                                                                                                                                                                                                                |
|                                        | <b>broadcast</b> <i>address</i><br>Defines the interface as broadcast capable (for example, Ethernet or Token Ring) and specifies the broadcast address.                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                        | <b>pointtopoint</b> <i>address</i><br>Defines the interface as a pointtopoint interface (for example, SLIP or PPP) and specifies the address on the local side. The first <i>address</i> on the <b>define</b> statement references the address of the host on the <b>remote</b> end of the interface, the <i>address</i> specified after this <b>pointtopoint</b> keyword defines the address on the <b>local</b> side of the interface.<br><br>An interface not defined as broadcast or pointtopoint is assumed to be non-broadcast multiaccess (NBMA), such as an X.25 network. |
|                                        | <b>netmask</b> <i>mask</i><br>Specifies the subnetmask to be used on this interface. This is ignored on pointtopoint interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                        | <b>multicast</b><br>Specifies that the interface is multicast capable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Interface Lists

An interface list is a list of references to interfaces or groups of interfaces. There are four methods available for referring to interfaces. They are listed here from most general to most specific.

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all</b>              | This refers to all available interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Interface name wildcard | This refers to all the interfaces of the same type. The operating system interfaces consist of the name of the device driver, like <b>en</b> , and a unit number, like <b>0</b> or <b>5</b> . References to the name contain only alphabetic characters and match any interfaces that have the same alphabetic part. For example, <b>en</b> would refer to all Ethernet interfaces.                                                                              |
| Interface name          | This refers to a specific interface, usually one physical interface. These are specified as an alphabetic part followed by a numeric part. This will match one specific interface. For example, <b>en1</b> will match an interface named <b>en1</b> , but not an interface named <b>en10</b> . In case there are multiple addresses aliased to a single interface, specify the particular ip address to be used by <b>gated</b> , instead of the interface name. |
| Interface address       | This matches one specific interface. The reference can be by protocol address (that is, <b>10.0.0.51</b> ), or by symbolic hostname (that is, <b>hornet.ibm.com</b> ). Note that a symbolic hostname reference is only valid when it resolves to only one address. Use of symbolic hostnames is not recommended.                                                                                                                                                 |

If many interface lists are present in the config file with more than one parameter, these parameters are collected at run-time to create the specific parameter list for a given interface. If the same parameter is specified on more than one list, the parameter with the most specific interface is used.

For example, consider a system with three interfaces: `en0`, `en1`, and `tr0`.

```
rip yes {
 interface all noripin noripout;
interface en ripin;
interface en1 ripout;
} ;
```

RIP packets would only be accepted from interfaces `en0` and `en1`, but not from `tr0`. RIP packets would only be sent on interface `en1`.

## IP Interface Addresses and Routes

| Item                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>loopback</code>                                        | This interface must have the address of <code>127.0.0.1</code> . Packets sent to this interface are sent back to the originator. This interface is also used as a catch-all interface for implementing other features, such as <code>reject</code> and <code>blackhole</code> routes. Although a netmask is reported on this interface, it is ignored. It is useful to assign an additional address to this interface that is the same as the OSPF or BGP router id; this allows routing to a system based on the router id that will work if some interfaces are down. |
| <code>broadcast</code>                                       | This is a multi-access interface capable of a physical level broadcast, such as Ethernet, Token Ring, and FDDI. This interface has an associated subnet mask and broadcast address. The interface route to a broadcast network will be a route to the complete subnet.                                                                                                                                                                                                                                                                                                  |
| <code>point-to-point</code>                                  | This is a tunnel to another host, usually on some sort of serial link. This interface has a local address, and a remote address.<br><br>The remote address must be unique among all the interface addresses on a given router. The local address may be shared among many point-to-point and up to one non-point-to-point interface. This is technically a form of the router id method for addressless links. This technique conserves subnets as none are required when using this technique.                                                                         |
| <code>non-broadcast multi-access</code> or <code>nbma</code> | If a subnet mask is specified on a point-to-point interface, it is only used by RIP version 1 and HELLO to determine which subnets may be propagated to the router on the other side of this interface.<br><br>This type of interface is multi-access, but not capable of broadcast. An example would be frame relay and X.25. This type of interface has a local address and a subnet mask.                                                                                                                                                                            |

The **gated** daemon ensures that there is a route available to each IP interface that is configured and up. Normally this is done by the `ifconfig` command that configures the interface; the **gated** daemon does it to ensure consistency.

For point-to-point interfaces, the **gated** daemon installs some special routes. If the local address on one or more point-to-point interfaces is not shared with a non-point-to-point interface, the **gated** daemon installs a route to the local address pointing at the loopback interface with a preference of 110. This ensures that packets originating on this host destined for this local address are handled locally. OSPF prefers to route packets for the local interface across the point-to-point link where they will be returned by the router on the remote end. This is used to verify operation of the link. Since OSPF installs routes with a preference of 10, these routes will override the route installed with a preference of 110.

If the local address of one or more point-to-point interfaces is shared with a non-point-to-point interface, the **gated** daemon installs a route to the local with a preference of 0 that will not be installed in the forwarding table. This is to prevent protocols like OSPF from routing packets to this address across a serial interface when this system could be functioning as a host.

When the status of an interface changes, the **gated** daemon notifies all the protocols, which take the appropriate action. The **gated** daemon assumes that interfaces that are not marked UP do not exist.

The **gated** daemon ignores any interfaces that have invalid data for the local, remote, or broadcast addresses or the subnet mask. Invalid data includes zeros in any field. The **gated** daemon will also ignore any point-to-point interface that has the same local and remote addresses.

## Definition Statements

Definition statements are general configuration statements that relate to all of **gated** daemon or at least to more than one protocol. The three definition statements are **autonomoussystem**, **routerid**, and **martians**. If used, **autonomoussystem**, **routerid**, and **martians** must appear before any other type of configuration statement in the **gated** daemon file.

### Autonomous System Configuration

```
autonomoussystem autonomous_system [loops number] ;
```

Sets the autonomous system number of this router to be autonomous system. This option is required if BGP or EGP are in use. The AS number is assigned by the Network Information Center (NIC).

Loops is only for protocols supporting AS paths, such as BGP. It controls the number of times this autonomous system may appear in an AS path and defaults to 1 (one).

### Router ID Configuration

```
routerid host ;
```

Sets the router identifier for use by the BGP and OSPF protocols. The default is the address of the first interface encountered by the **gated** daemon. The address of a non-point-to-point interface is preferred over the local address of a point-to-point interface and an address on a loopback interface that is not the loopback address (127.0.0.1) is most preferred.

### Martian Configuration

```
martians {
 host host [allow] ;
 network [allow] ;
 network mask mask [allow] ;
 network masklen number [allow] ;
 default [allow] ;
}
```

Defines a list of martian addresses about which all routing information is ignored. Sometimes a misconfigured system sends out obviously invalid destination addresses. These invalid addresses, called martians, are rejected by the routing software. This command allows additions to the list of martian addresses. See the section on Route Filtering for more information on specifying ranges. Also, the *allow* parameter may be specified to explicitly allow a subset of a range that was disallowed.

### Sample Definition Statements

```
options gendefault ;
autonomoussystem 249 ;
interface 128.66.12.2 passive ;
martians {
 0.0.0.26
};
```

The statements in the sample perform the following functions:

- The options statement tells the system to generate a default route when it peers with an EGP or BGP neighbor.

- The **autonomoussystem** statement tells the **gated** daemon to use the AS number 249 for EGP and BGP.
- The **interface** statement tells the **gated** daemon not to mark interface 128.66.12.2 as down even if it sees no traffic.
- The **martians** statement prevents routes to 0.0.0.26 from ever being accepted.

## The RIP Statement

```
rip yes | no | on | off [{
 broadcast ;
 nobroadcast ;
 nocheckzero ;
 preference preference ;
 defaultmetric metric ;
 query authentication [none | [[simple|md5] password]] ;
 interface interface_list
 [noripin] | [ripin]
 [noripout] | [ripout]
 [metricin metric]
 [metricout metric]
 [version 1] | [version 2 [multicast|broadcast]]
 [[secondary] authentication [none | [[simple|md5] password]] ;
 trustedgateways gateway_list ;
 sourcegateways gateway_list ;
 traceoptions trace_options ;
}] ;
```

The **rip** statement enables or disables RIP. If the **rip** statement is not specified, the default is **rip on** ;. If enabled, RIP will assume **nobroadcast** when there is only one interface and **broadcast** when there is more than one.

The options are as follows:

### **broadcast**

Specifies that RIP packets will be broadcast regardless of the number of interfaces present. This is useful when propagating static routes or routes learned from another protocol into RIP. In some cases, the use of **broadcast** when only one network interface is present can cause data packets to traverse a single network twice.

### **nobroadcast**

Specifies that RIP packets will not be broadcast on attached interfaces, even if there is more than one. If a **sourcegateways** clause is present, routes will still be unicast directly to that gateway.

### **nocheckzero**

Specifies that RIP should not make sure that reserved fields in incoming version 1 RIP packets are zero. Normally RIP will reject packets where the reserved fields are zero.

### **preference *preference***

Sets the preference for routes learned from RIP. The default preference is 100. This preference may be overridden by a preference specified in import policy.

### **defaultmetric *metric***

Defines the metric used when advertising routes via RIP were learned from other protocols. If not specified, the default value is 16 (unreachable). This choice of values requires you to explicitly specify a metric in order to export routes from other protocols into RIP. This metric may be overridden by a metric specified in export policy.

**query authentication [none | [[simple|md5] password]] ;**

Specifies the authentication required of query packets that do not originate from routers. The default is none.

**interface interface\_list**

Controls various attributes of sending RIP on specific interfaces. See the section on interface list specification for a description of the *interface\_list*.

**Note:** If there are multiple interfaces configured on the same subnet, RIP updates will only be sent from the first one from which RIP output is configured.

The possible parameters are:

**noripin**

Specifies that RIP packets received via the specified interface will be ignored. The default is to listen to RIP packets on all non-loopback interfaces.

**ripin** This is the default. This argument may be necessary when **noripin** is used on a wildcard interface descriptor.

**noripout**

Specifies that no RIP packets will be sent on the specified interfaces. The default is to send RIP on all broadcast and non-broadcast interfaces when in broadcast mode. The sending of RIP on point-to-point interfaces must be manually configured.

**ripout** This is the default. This argument is necessary when it is desired to send RIP on point-to-point interfaces and may be necessary when **noripin** is used on a wildcard interface descriptor.

**metricin metric**

Specifies the RIP metric to add to incoming routes before they are installed in the routing table. The default is the kernel interface metric plus 1 (which is the default RIP hop count). If this value is specified it will be used as the absolute value, the kernel metric will not be added. This option is used to make this router prefer RIP routes learned via the specified interface(s) less than RIP routes from other interfaces.

**metricout metric**

Specifies the RIP metric to be added to routes that are sent via the specified interface(s). The default is zero. This option is used to make other routers prefer other sources of RIP routes over this router.

**version 1**

Specifies that RIP packets sent via the specified interface(s) will be version 1 packets. This is the default.

**version 2**

Specifies that RIP version 2 packets will be sent on the specified interface(s). If IP multicast support is available on this interface, the default is to send full version 2 packets. If it is not available, version 1 compatible version 2 packets will be sent.

**multicast**

Specifies that RIP version 2 packets should be multicast on this interface. This is the default.

**broadcast**

Specifies that RIP version 1 compatible version 2 packets should be broadcast on this interface, even if IP multicast is available.

**[secondary] authentication [none | [simple|md5] password]**

This defines the authentication type to use. It applies only to RIP version 2 and is ignored

for RIP-1 packets. The default authentication type is none. If a password is specified, the authentication type defaults to simple. The password should be a quoted string with between 0 and 16 characters.

If secondary is specified, this defines the secondary authentication. If omitted, the primary authentication is specified. The default is primary authentication of none and no secondary authentication.

#### **trustedgateways** *gateway\_list*

Defines the list of gateways from which RIP will accept updates. The *gateway\_list* is simply a list of host names or IP addresses. By default, all routers on the shared network are trusted to supply routing information. But if the trustedgateways clause is specified, only updates from the gateways in the list are accepted.

#### **sourcegateways** *gateway\_list*

Defines a list of routers to which RIP sends packets directly, not through multicast or broadcast. This can be used to send different routing information to specific gateways. Updates to gateways in this list are not affected by noripout on the interface.

#### **traceoptions** *trace\_options*

Specifies the tracing options for RIP. (See Trace Statements and the RIP specific tracing options below.)

## **Tracing options**

The policy option logs info whenever a new route is announced, the metric being announced changes, or a route goes or leaves holddown.

Packet tracing options (which may be modified with detail, send, or recv):

| Item     | Description                                                                                          |
|----------|------------------------------------------------------------------------------------------------------|
| packets  | All RIP packets.                                                                                     |
| request  | All RIP information request packets, such as REQUEST, POLL, and POLLENTRY.                           |
| response | All RIP RESPONSE packets, which are the types of packets that actually contains routing information. |
| other    | Any other type of packet. The only valid ones are TRACE_ON and TRACE_OFF both of which are ignored.  |

## **The RIPNG Statement**

Enables or disables ripng. If the ripng statement is not specified, the default is ripng on ; The options are the same as for rip, but all the addresses will be IPv6 addresses.

The syntax is:

```
ripng yes | no | on | off [{
 broadcast ;
 nobroadcast ;
 nocheckzero ;
 preference <preference> ;
 defaultmetric <metric> ;
 query authentication [none | [[simple|md5] <password>]] ;
 interface <interface_list>
 [noripin] | [ripin]
 [noripout] | [ripout]
 [metricin <metric>]
 [metricout <metric>]
 [version 1] | [version 2 [multicast|broadcast]]
 [[secondary] authentication [none | [[simple|md5] <password>]]] ;
 trustedgateways <gaeway_list> ;
 sourcegateways <gaeway_list> ;
 traceoptions <trace_options> ;
}] ;
```

## The Hello Statement

```
hello yes | no | on | off [{
 broadcast ;
 nobroadcast ;
 preference preference ;
 defaultmetric metric ;
 interface interface_list
 [nohelloin] | [helloin]
 [nohellout] | [hellout]
 [metricin metric]
 [metricout metric] ;
 trustedgateways gateway_list ;
 sourcegateways gateway_list ;
 traceoptions trace_options ;
}] ;
```

The `hello` statement enables or disables HELLO. If the `hello` statement is not specified, the default is `hello off`. If enabled, HELLO will assume `nobroadcast` when there is only one interface and `broadcast` when there is more than one interface.

| Item                                      | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>broadcast</code>                    | Specifies that HELLO packets will be broadcast regardless of the number of interfaces present. This is useful when propagating static routes or routes learned from another protocol into HELLO. In some cases, the use of broadcast when only one network interface is present can cause data packets to traverse a single network twice.                  |
| <code>nobroadcast</code>                  | Specifies that HELLO packets will not be broadcast on attached interfaces, even if there are more than one. If a <code>sourcegateways</code> clause is present, routes will still be unicast directly to that gateway.                                                                                                                                      |
| <code>preference <i>preference</i></code> | Sets the preference for routes learned from HELLO. The default preference is <code>op</code> . This preference may be overridden by a preference specified in import policy.                                                                                                                                                                                |
| <code>defaultmetric <i>metric</i></code>  | Defines the metric used when advertising routes via HELLO were learned from other protocols. If not specified, the default value is 30000 (unreachable). This choice of values requires you to explicitly specify a metric in order to export routes from other protocols into HELLO. This metric may be overridden by a metric specified in export policy. |

| Item                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>interface_list</i>     | Controls various attributes of sending HELLO on specific interfaces. See the section on interface list specification for the description of the <i>interface_list</i> .<br><b>Note:</b> If there are multiple interfaces configured on the same subnet, HELLO updates will only be sent from the first one from which the HELLO output is configured.                                                                                                  |
|                                            | The possible parameters are:                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                                            | <b>nohelloin</b>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                                            | Specifies that HELLO packets received via the specified interface will be ignored. The default is to listen to HELLO on all non-loopback interfaces.                                                                                                                                                                                                                                                                                                   |
|                                            | <b>helloin</b> This is the default. This argument may be necessary when nohelloin is used on a wildcard interface descriptor.                                                                                                                                                                                                                                                                                                                          |
|                                            | <b>nohelloout</b>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|                                            | Specifies that no HELLO packets will be sent on the specified interfaces. The default is to send HELLO on all broadcast and non-broadcast interfaces when in broadcast mode. The sending of HELLO on point-to-point interfaces must be manually configured.                                                                                                                                                                                            |
|                                            | <b>helloout</b> This is the default. This argument is necessary when it is desired to send HELLO on point-to-point interfaces and may be necessary when nohelloin is used on a wildcard interface descriptor.                                                                                                                                                                                                                                          |
|                                            | <b>metricin</b> <i>metric</i>                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                            | Specifies the HELLO metric to add to incoming routes before they are installed in the routing table. The default is the kernel interface metric plus 1 (which is the default HELLO hop count). If this value is specified it will be used as the absolute value; the kernel metric will not be added. This option is used to make this router prefer HELLO routes learned via the specified interface(s) less than HELLO routes from other interfaces. |
|                                            | <b>metricout</b> <i>metric</i>                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                            | Specifies the HELLO metric to be added to routes that are sent via the specified interface(s). The default is zero. This option is used to make other routers prefer other sources of HELLO routes over this router.                                                                                                                                                                                                                                   |
| <b>trustedgateways</b> <i>gateway_list</i> | Defines the list of gateways from which HELLO will accept updates. The <i>gateway_list</i> is simply a list of host names or IP addresses. By default, all routers on the shared network are trusted to supply routing information. But if the trustedgateways clause is specified, only updates from the gateways in the list are accepted.                                                                                                           |
| <b>sourcegateways</b> <i>gateway_list</i>  | Defines a list of routers to which HELLO sends packets directly, not through multicast or broadcast. This can be used to send different routing information to specific gateways. Updates to gateways in this list are not affected by noripout on the interface.                                                                                                                                                                                      |
| <b>traceoptions</b> <i>trace_options</i>   | Specifies the tracing options for HELLO. (See Trace Statements and the HELLO specific tracing options below.)                                                                                                                                                                                                                                                                                                                                          |

The default preference is 90. The default metric is 30000.

## Tracing options

The policy option logs info whenever a new route is announced, the metric being announced changes, or a route goes or leaves holddown.

Packet tracing options (which may be modified with detail, send, and/or recv):

| Item    | Description       |
|---------|-------------------|
| packets | All HELLO packets |

## The IS-IS Statement

```
isis no | dual | ip | iso {
 level 1|2 ;
 [traceoptions <isis_traceoptions> ;]
 [systemid <6_digit_hexstring> ;]
 [area <hexstring> ;]
 [set <isis_parm> <value> ; ...]
 circuit <string>
 metric [level 1|2] <1..63>
 ...
 priority [level 1|2] <0..127>
 ...
 ;
...
}
;
```

This statement enables the IS-IS protocol in the **gated** daemon. By default, IS-IS is disabled. The **dual** option specifies that the IS-IS protocol is enabled for both ISO and IP addressing. The **isis** statement consists of an initial description of the IS and a list of statements that determine the configuration of the specific circuits and networks to be managed. Statements may appear in any order and include:

| Item                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>level</b>        | Indicates whether <b>gated</b> is running on a Level 1 (intra-area) or Level 2 (inter-area) IS. The default is Level 1.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>traceoptions</b> | Covered in the Tracing options section below.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>systemid</b>     | Overrides the autoconfigured system ID (determined from interface addresses and corresponding netmasks). If no system identifier is specified, the system ID portion of the first real circuit's NSAP is used. Once a system ID is set, it cannot be changed without disabling and reenabling all of IS-IS.                                                                                                                                                                                     |
| <b>area</b>         | IS-IS area addresses are automatically configured based on the real circuits over which IS-IS runs. Addresses specified in this statement are maintained in addition to those configured automatically from the circuits. This command is used primarily for simulation.                                                                                                                                                                                                                        |
| <b>circuit</b>      | Each <b>circuit</b> statement specifies one of the circuits the system will manage. Circuits normally correspond to UNIX interfaces, with <b>string</b> being the interface name, but simulated device names may also be specified. If the string is in the form of "simN", where N is an integer, the circuit is assumed to be a simulated circuit managed by the network simulator troll. The circuit attributes are a list of options that may appear in any order in the circuit statement. |
| <b>metric</b>       | Allows specifications of Level 1 and Level 2 metrics for each circuit. Only the default metric type is supported. IS-IS metrics must be in the range 1 to 63. If no metric is set for the circuit, the default value is 63.                                                                                                                                                                                                                                                                     |
| <b>priority</b>     | Determines designated router election results; higher values give a higher likelihood of becoming the designated router. The level defaults to Level 1. If no priority is specified, priority is set to a random value between 0 and 127.                                                                                                                                                                                                                                                       |

On a level 2 IS, to configure a circuit with a Level 1 metric of 10 and a Level 2 metric of 20, add two metric options to the circuit statement.

The default Level is 1: the default metric is 63. The default preference for IS-IS Level 1 is 15 for IS-IS Level 2 is 18.

## Tracing options

Traceoptions can be one or more of the following:

```
all
iih
lanadj
p2padj
lspdb
```

```
lspcontent
lspinput
flooding
buildlsp
csnp
psnp
route
update
paths
spf
events
```

## The OSPF Statement

```
ospf yes | no | on | off [
 defaults {
 preference preference ;
 cost cost ;
 tag [as] tag ;
 type 1 | 2 ;
 } ;
 exportlimit routes ;
 exportinterval time ;
 traceoptions trace_options ;
 monitorauthkey authkey ;
 monitorauth none | ([simple | md5] authkey) ;
 backbone | (area area) {
 authtype 0 | 1 | none | simple | md5 ;
 stub [cost cost] ;
 networks {
 network [restrict] ;

```

The following are the *interface\_parameters* referred to above. They may be specified on any class of interface and are described under the *interface* clause.

```
enable | disable;
retransmitinterval time;
transitdelay time;
priority priority;
hellointerval time;
routerdeadinterval time;
authkey auth_key | auth md5 key auth_key id key_id ;
```

#### **defaults**

These parameters specify the defaults used when importing OSPF ASE routes into the gated routing table and exporting routes from the gated routing table into OSPF ASEs.

#### **preference preference**

**Preference** is used to determine how OSPF routes compete with routes from other protocols in the gated routing table. The default value is 150.

#### **cost cost**

**Cost** is used when exporting a non-OSPF route from the gated routing table into OSPF as an ASE. The default value is 1. This may be explicitly overridden in export policy.

#### **tag [as ] tag**

OSPF ASE routes have a 32 bit tag field that is not used by the OSPF protocol, but may be used by export policy to filter routes. When OSPF is interacting with an EGP, the tag field may be used to propagate AS path information, in which case the as keyword is specified and the tag is limited to 12 bits of information. If not specified, the tag is set to zero.

#### **type 1 | 2**

Routes exported from the gated routing table into OSPF default to becoming type 1 ASEs. This default may be explicitly changed here and overridden in export policy.

### **ASE export rate**

Because of the nature of OSPF, the rate at which ASEs are flooded must be limited. These two parameters can be used to adjust those rate limits.

#### **exportinterval time**

This specifies how often a batch of ASE link state advertisements will be generated and flooded into OSPF. The default is once per second.

#### **exportlimit routes**

This parameter specifies how many ASEs will be generated and flooded in each batch. The default is 100.

#### **traceoptions trace\_options**

Specifies the tracing options for OSPF. (See Trace Statements and the OSPF specific tracing options below.)

#### **monitorauthkey authkey**

OSPF state may be queried using the **ospf\_monitor** command utility. This utility sends non-standard OSPF packets that generate a text response from OSPF. By default, these requests are not authenticated if an authentication key is configured, the incoming requests must match the specified authentication key. No OSPF state may be changed by these packets, but the act of querying OSPF can utilize system resources.

#### **backbonearea area**

Each OSPF router must be configured into at least one OSPF area. If more than one area is configured, at least one must be backbone. The backbone may only be configured using the **backbone** keyword, it may not be specified as area 0. The backbone interface may be a **virtuallink**.

#### **authtype 0 | 1 | none | simple | md5**

OSPF specifies an authentication scheme per area. Each interface in the area must use this same authentication scheme although it may use a different authenticationkey. The

currently valid values are none (0) for no authentication, simple (1) for simple password authentication or md5 for MD5 authentication.

#### **stub [cost cost]**

A stub area is one in which there are no ASE routes. If a cost is specified, this is used to inject a default route into the area with the specified cost.

#### **networks**

The networks list describes the scope of an area. Intra-area LSAs that fall within the specified ranges are not advertised into other areas as inter-area routes. Instead, the specified ranges are advertised as summary network LSAs. If **restrict** is specified, the summary network LSAs are not advertised. Intra-area LSAs that do not fall into any range are also advertised as summary network LSAs. This option is very useful on well designed networks in reducing the amount of routing information propagated between areas. The entries in this list are either networks, or a subnetwork/mask pair. See the section on Route Filtering for more detail about specifying ranges.

#### **stubhosts**

This list specifies directly attached hosts that should be advertised as reachable from this router and the costs they should be advertised with. Point-to-point interfaces on which it is not desirable to run OSPF should be specified here.

It is also useful to assign an additional address to the loopback interface (one not on the 127 network) and advertise it as a stub hosts. If this address is the same one used as the router-id, it enables routing to OSPF routers by router-id, instead of by an interface address. This is more reliable than routing to one of the router's interface addresses that may not always be reachable.

#### **interface *interface\_list* [cost *cost* ]**

This form of the interface clause is used to configure a broadcast (which requires IP multicast support) or a point-to-point interface. See the section on interface list specification for the description of the *interface\_list*.

Each interface has a cost. The costs of all interfaces a packet must cross to reach a destination are summed to get the cost to that destination. The default cost is one, but another non-zero value may be specified.

Interface parameters common to all types of interfaces are:

#### **retransmitinterval *time***

The number of seconds between link state advertisement retransmissions for adjacencies belonging to this interface.

#### **transitdelay *time***

The estimated number of seconds required to transmit a link state update over this interface. **Transitdelay** takes into account transmission and propagation delays and must be greater than 0.

#### **priority *priority***

A number between 0 and 255 specifying the priority for becoming the designated router on this interface. When two routers attached to a network both attempt to become the designated router, the one with the highest priority wins. A router whose router priority is set to 0 is ineligible to become the designated router.

#### **hellointerval *time***

The length of time, in seconds, between Hello packets that the router sends on the interface.

#### **routerdeadinterval *time***

The number of seconds not hearing a router's Hello packets before the router's neighbors will declare it down.

**authkey** *auth\_key* | **auth md5 key** *auth\_key* **id** *key\_id* ;

Used by OSPF authentication to generate and verify the authentication field in the OSPF header. The authentication key can be configured on a per interface basis. It is specified by one to eight decimal digits separated by periods, a one to eight byte hexadecimal string preceded by 0x, or a one to eight character string in double quotes.

For MD5 authentication, the **auth\_key** is specified by a 1 to 8 character string in double quotes. The **id** specifies the algorithm used by MD5 to calculate the message-digest and its value ranges from 1 to 255.

Point-to-point interfaces also support this additional parameter:

#### **nomulticast**

By default, OSPF packets to neighbors on point-to-point interfaces are sent via the IP multicast mechanism. If the use of IP multicasting is not desired, the *nomulticast* parameter may be specified to force the use of unicast OSPF packets. **gated.conf** will detect this condition and fall back to using sending unicast OSPF packets to this point-to-point neighbor.

If the use of IP multicasting is not desired because the remote neighbor does not support it, the *nomulticast* parameter may be specified to force the use of unicast OSPF packets. This option may also be used to eliminate warnings when **gated.conf** detects the bug mentioned above.

**interface** *interface\_list* **nonbroadcast** [**cost** *cost* ]

This form of the interface clause is used to specify a nonbroadcast interface on a non-broadcast multi-access (NBMA) media. Since an OSPF broadcast media must support IP multicasting, a broadcast-capable media, such as Ethernet, that does not support IP multicasting must be configured as a non-broadcast interface.

A non-broadcast interface supports any of the standard interface clauses listed above, plus the following two that are specific to non-broadcast interfaces:

#### **pollinterval** *time*

Before adjacency is established with a neighbor, OSPF packets are sent periodically at the specified pollinterval.

#### **routers**

By definition, it is not possible to send broadcast packets to discover OSPF neighbors on a non-broadcast, so all neighbors must be configured. The list includes one or more neighbors and an indication of their eligibility to become a designated router.

**virtuallink** **neighborid** *router\_id* **transitarea** *area*

Virtual links are used to establish or increase connectivity of the backbone area. The neighborid is the *router\_id* of the other end of the virtual link. The transit area specified must also be configured on this system. All standard interface parameters defined by the interface clause above may be specified on a virtual link.

### Tracing options

In addition to the following OSPF specific trace flags, OSPF supports the state that traces interface and neighbor state machine transitions.

| Item     | Description                            |
|----------|----------------------------------------|
| lsabuild | Link State Advertisement creation      |
| spf      | Shortest Path First (SPF) calculations |

Packet tracing options (which may be modified with detail, send and recv):

| Item    | Description                                                                      |
|---------|----------------------------------------------------------------------------------|
| hello   | OSPF HELLO packets that are used to determine neighbor reachability.             |
| dd      | OSPF Database Description packets that are used in synchronizing OSPF databases. |
| request | OSPF Link State Request packets that are used in synchronizing OSPF databases.   |
| lsu     | OSPF Link State Update packets that are used in synchronizing OSPF databases.    |
| ack     | OSPF Link State Ack packets that are used in synchronizing OSPF databases.       |

## The EGP Statement

```

EGP yes | no | on | off
[{
 preference preference ;
 defaultmetric metric ;
 packetsize number ;
 traceoptions trace_options ;
 group
 [peeras autonomous_system]
 [localas autonomous_system]
 [maxup number]
 {
 neighbor host
 [metricout metric]
 [preference preference]
 [preference2 preference]
 [ttl ttl]
 [nogedefault]
 [importdefault]
 [exportdefault]
 [gateway gateway]
 [lcladdr local_address]
 [sourcenet network]
 [minhello | p1 time]
 [minpoll | p2 time]
 [traceoptions trace_options]
 ;
 }
}
];
preference preference
Sets the preference for routes learned from RIP. The default preference is 200. This preference may be overridden by a preference specified on the group or neighbor statements or by import policy.

defaultmetric metric ;
Defines the metric used when advertising routes via EGP. If not specified, the default value is 255 that some systems may consider unreachable. This choice of values requires you to explicitly specify a metric when exporting routes to EGP neighbors. This metric may be overridden by a metric specified on the neighbor or group statements or in export policy.

packetsize maxpacketsize
This defines the expected maximum size of a packet that EGP expects to receive from this neighbor. If a packet larger than this value is received, it will be incomplete and have to be

```

discarded. The length of this packet will be noted and the expected size will be increased to be able to receive a packet of this size. Specifying the parameter here will prevent the first packet from being dropped. If not specified, the default size is 8192 bytes. All packet sizes are rounded up to a multiple of the system page size.

#### **traceoptions** *trace\_options*

Specifies the tracing options for EGP. By default these are inherited from the global trace options. These values may be overridden on a group or neighbor basis. (See Trace Statements and the EGP specific tracing options below.)

**group** EGP neighbors must be specified as members of a group. A group is usually used to group all neighbors in one autonomous system. Parameters specified on the group clause apply to all of the subsidiary neighbors unless explicitly overridden on a neighbor clause. Any number of group clauses may specify any number of neighbor clauses.

Any parameters from the neighbor subclause may be specified on the group clause to provide defaults for the whole group (which may be overridden for individual neighbors). In addition, the group clause is the only place to set the following attributes:

**peeras** Identifies the autonomous system number expected from peers in the group. If not specified, it will be learned dynamically.

#### **localas**

Identifies the autonomous system that **gated.conf** is representing to the group. The default is that which has been set globally in the **autonomoussystem** statement. This option is usually only used when *masquerading* as another autonomous system and its use is discouraged.

#### **maxup**

Specifies the number of neighbors the **gated** daemon should acquire from this group. The default is to acquire all of the neighbors in the group. The **gated** daemon will attempt to acquire the first maxup neighbors in the order listed. If one of the first neighbors is not available, it will acquire one further down the list. If after start-up the **gated** daemon does manage to acquire the more desirable neighbor, it will drop the less desirable one.

#### **neighbor** *neighbor\_address*

Each neighbor subclause defines one EGP neighbor within a group. The only part of the subclause that is required is the *neighbor\_address* argument that is the symbolic host name or IP address of the neighbor. All other parameters are optional.

#### **preference** *preference*

Specifies the preference used for routes learned from these neighbors. This can differ from the default EGP preference set in the EGP statement, so that the **gated** daemon can prefer routes from one neighbor, or group of neighbors, over another. This preference may be explicitly overridden by import policy.

#### **preference2** *preference*

In the case of a preference tie, the second preference, preference2 may be used to break the tie. The default value is 0.

#### **metricout** *metric*

This defines a metric to be used for all routes sent to this neighbor. The value overrides the default metric set in the EGP statement and any metrics specified by export policy, but only for this specific neighbor or group of neighbors.

#### **nogendefault**

Prevents **gated.conf** from generating a default route when EGP receives a valid update from its neighbor. The default route is only generated when the **gendefault** option is enabled.

#### **importdefault**

Enables the **gated** daemon to accept the default route (0.0.0.0) if it is included in a

received EGP update. If not specified, the default route contained in an EGP update is ignored. For efficiency, some networks have external routers announce a default route to avoid sending large EGP update packets.

#### **exportdefault**

Enables the **gated** daemon to include the default route (0.0.0.0) in EGP updates sent to this EGP neighbor. This allows the system to advertise the default route via EGP. Normally a default route is not included in EGP updates.

#### **gateway gateway**

If a network is not shared with a neighbor, **gateway** specifies a router on an attached network to be used as the next hop router for routes received from this neighbor. This option is only rarely used.

#### **lcladdr local\_address**

Specifies the address to be used on the local end of the connection with the neighbor. The local address must be on an interface that is shared with the neighbor or with the neighbor's **gateway** when the **gateway** parameter is used. A session will only be opened when an interface with the appropriate local address (through which the neighbor or gateway address is directly reachable) is operating.

#### **sourcenet network**

Specifies the network queried in the EGP Poll packets. By default, this is the network shared with the neighbor's address specified. If there is no network shared with the neighbor, one of the networks the neighbor is attached to should be specified. This parameter can also be used to specify a network shared with the neighbor other than the one on which the EGP packets are sent. This parameter is normally not needed.

#### **p1 time**

#### **minhello time**

Sets the minimum acceptable interval between the transmission of EGP HELLO packets. The default hello interval is 30 seconds. If the neighbor fails to respond to three hello packets, the **gated** daemon stops trying to acquire the neighbor. Setting a larger interval gives the neighbor a better chance to respond. **Minhello** is an alias for the P1 value defined in the EGP specification.

#### **p2 time**

#### **minpoll time**

Sets the time interval between polls to the neighbor. The default is 120 seconds. If three polls are sent without a response, the neighbor is declared "down" and all routes learned from that neighbor are removed from the routing database. A longer polling interval supports a more stable routing database but is not as responsive to routing changes. **Minpoll** is an alias for the P2 value defined in the EGP specification.

#### **ttl ttl**

By default, the **gated** daemon sets the IP TTL for local neighbors to *one* and the TTL for non-local neighbors to 255. This option is provided when attempting to communicate with improperly functioning routers that ignore packets sent with a TTL of one.

#### **traceoptions trace\_options**

Specifies the tracing options for this EGP neighbor. By default, these are inherited from group or EGP global trace options. (See Trace Statements and the EGP specific tracing options below.)

### Tracing options

The state and policy options work with EGP.

Packet tracing options (which may be modified with detail, send and recv):

| Item    | Description                                                                        |
|---------|------------------------------------------------------------------------------------|
| packets | All EGP packets                                                                    |
| hello   | EGP HELLO/I-HEARD-U packets that are used to determine neighbor reachability.      |
| acquire | EGP ACQUIRE/CEASE packets that are used to initiate and terminate EGP sessions.    |
| update  | EGP POLL/UPDATE packets that are used to request and receive reachability updates. |

## The BGP Statement

```

```

The `bgp` statement enables or disables BGP. By default, BGP is disabled. The default metric for announcing routes via BGP is not to send a metric.

| Item                                    | Description                                                                                                                                                                                                                          |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>preference preference</code>      | Sets the preference for routes learned from RIP. The default preference is 170. This preference may be overridden by a preference specified on the group or peer statements or by import policy.                                     |
| <code>defaultmetric metric</code>       | Defines the metric used when advertising routes via BGP. If not specified, no metric is propagated. This metric may be overridden by a metric specified on the neighbor or group statements or in export policy.                     |
| <code>traceoptions trace_options</code> | Specifies the tracing options for BGP. By default these are inherited from the global trace options. These values may be overridden on a group or neighbor basis. (See Trace Statements and the BGP specific tracing options below.) |

## Groups

BGP peers are grouped by type and the autonomous system of the peers. Any number of groups may be specified, but each must have a unique combination of type and peer autonomous system. There are four possible group types:

### `group type external peers as autonomous_system`

In the classic external BGP group, full policy checking is applied to all incoming and outgoing advertisements. The external neighbors must be directly reachable through one of the machine's local interfaces. By default no metric is included in external advertisements, and the next hop is computed with respect to the shared interface.

### `group type internal peers as autonomous_system`

An internal group operating where there is no IP-level IGP. All neighbors in this group are required to be directly reachable via a single interface. All next hop information is computed with respect to this interface. Import and export policy may be applied to group advertisements. Routes received from external BGP or EGP neighbors are by default readvertised with the received metric.

### `group type IGP peers as autonomous_system proto proto`

An internal group that runs in association with an interior protocol. The IGP group examines routes that the IGP is exporting and sends an advertisement only if the path attributes could not be entirely represented in the IGP tag mechanism. Only the AS path, path origin, and transitive optional attributes are sent with routes. No metric is sent, and the next hop is set to the local address used by the connection. Received internal BGP routes are not used or readvertised. Instead, the AS path information is attached to the corresponding IGP route and the latter is used for readvertisement. Since internal IGP peers are sent only a subset of the routes that the IGP is exporting, the export policy used is the IGP's. There is no need to implement the "don't routes from peers in the same group" constraint since the advertised routes are routes that IGP already exports.

### `group type routing peers as autonomous_system proto proto interface interface_list`

An internal group that uses the routes of an interior protocol to resolve forwarding addresses. A type routing group propagates external routes between routers that are not directly connected, and computes immediate next hops for these routes by using the BGP next hop that arrived with the route as a forwarding address to be resolved via an internal protocol's routing information. In essence, internal BGP is used to carry AS external routes, while the IGP is expected to only carry AS internal routes, and the latter is used to find immediate next hops for the former.

The `proto` names the interior protocol to be used to resolve BGP route next hops, and may be the name of any IGP in the configuration. By default, the next hop in BGP routes advertised to type routing peers will be set to the local address on the BGP connection to those peers, as it is

assumed a route to this address will be propagated via the IGP. The *interface\_list* can optionally provide list interfaces whose routes are carried via the IGP for which third party next hops may be used instead.

#### **group type test peers as *autonomous\_system***

An extension to external BGP that implements a fixed policy using test peers. Fixed policy and special case code make test peers relatively inexpensive to maintain. Test peers do not need to be on a directly attached network. If the **gated** daemon and the peer are on the same (directly attached) subnet, the advertised next hop is computed with respect to that network, otherwise the next hop is the local machine's current next hop. All routing information advertised by and received from a test peer is discarded, and all BGP advertisable routes are sent back to the test peer. Metrics from EGP- and BGP-derived routes are forwarded in the advertisement, otherwise no metric is included.

## **Group parameters**

The BGP statement has group clauses and peer subclauses. Any number of peer subclauses may be specified within a group. A group clause usually defines default parameters for a group of peers, these parameters apply to all subsidiary peer subclauses. Any parameters from the peer subclause may be specified on the group clause to provide defaults for the whole group (which may be overridden for individual peers).

## **Specifying peers**

Within a group, BGP peers may be configured in one of two ways. They may be explicitly configured with a **peer** statement, or implicitly configured with the **allow** statement. Both are described here:

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>allow</b>            | The allow clause allows for peer connections from any addresses in the specified range of network and mask pairs. All parameters for these peers must be configured on the group clause. The internal peer structures are created when an incoming open request is received and destroyed when the connection is broken. For more detail on specifying the network/mask pairs, see the section on Route Filtering. |
| <b>peer <i>host</i></b> | A peer clause configures an individual peer. Each peer inherits all parameters specified on a group as defaults. Those defaults may be overridden by parameters explicitly specified on the peer subclause.                                                                                                                                                                                                        |

Within each group clause, individual peers can be specified or a group of *potential* peers can be specified using **allow**. **Allow** is used to specify a set of address masks. If the **gated** daemon receives a BGP connection request from any address in the set specified, it will accept it and set up a peer relationship.

## **Peer parameters**

The BGP peer subclause allows the following parameters, which can also be specified on the group clause. All are optional.

#### **metricout *metric***

If specified, this metric is used as the primary metric on all routes sent to the specified peer(s). This metric overrides the default metric, a metric specified on the group and any metric specified by export policy.

#### **localas *autonomous\_system***

Identifies the autonomous system that the **gated** daemon is representing to this group of peers. The default is that which has been set globally in the **autonomoussystem** statement.

#### **nogendefault**

Prevents **gated.conf** from generating a default route when EGP receives a valid update from its neighbor. The default route is only generated when the **gendefault** option is enabled.

**gateway** *gateway*

If a network is not shared with a peer, gateway specifies a router on an attached network to be used as the next hop router for routes received from this neighbor. This parameter is not needed in most cases.

**preference** *preference*

Specifies the preference used for routes learned from these peers. This can differ from the default BGP preference set in the bgp statement, so that the **gated** daemon can prefer routes from one peer, or group of peer, over others. This preference may be explicitly overridden by import policy.

**preference2** *preference*

In the case of a preference tie, the second preference, preference2 may be used to break the tie. The default value is 0.

**lcladdr** *local\_address*

Specifies the address to be used on the local end of the TCP connection with the peer. For external peers the local address must be on an interface that is shared with the peer or with the peer's gateway when the gateway parameter is used. A session with an external peer will only be opened when an interface with the appropriate local address (through which the peer or gateway address is directly reachable) is operating. For other types of peers, a peer session will be maintained when any interface with the specified local address is operating. In either case, incoming connections will only be recognized as matching a configured peer if they are addressed to the configured local address.

**holdtime** *time*

Specifies the BGP holdtime value to use when negotiating the connection with this peer, in seconds. According to BGP, if the **gated** daemon does not receive a keepalive, update, or notification message within the period specified in the Hold Time field of the BGP Open message, then the BGP connection will be closed. The value must be either 0 (no keepalives will be sent) or at least 3.

**version** *version*

Specifies the version of the BGP protocol to use with this peer. If not specified, the highest supported version is used first and version negotiation is attempted. If it is specified, only the specified version will be offered during negotiation. Currently supported versions are 2, 3 and 4.

**passive**

Specifies that active OPENS to this peer should not be attempted. the **gated** daemon should wait for the peer to issue an OPEN. By default, all explicitly configured peers are active, they periodically send OPEN messages until the peer responds.

**indelay** *time***outdelay** *time*

Used to dampen route fluctuations. Indelay is the amount of time a route learned from a BGP peer must be stable before it is accepted into the gated routing database. Outdelay is the amount of time a route must be present in the gated routing database before it is exported to BGP. The default value for each is 0, meaning that these features are disabled.

**keep all**

Used to retain routes learned from a peer even if the routes' AS paths contain one of our exported AS numbers.

**noaggregatorid**

Causes the **gated** daemon to specify the routerid in the aggregator attribute as zero (instead of its routerid) in order to prevent different routers in an AS from creating aggregate routes with different AS paths.

### **keepalivesalways**

Causes the **gated** daemon to always send keepalives, even when an update could have correctly substituted for one. This allows interoperability with routers that do not completely obey the protocol specifications on this point.

### **v3asloopokay**

By default, the **gated** daemon will not advertise routes whose AS path is looped (that is, with an AS appearing more than once in the path) to version 3 external peers. Setting this flag removes this constraint. Ignored when set on internal groups or peers.

### **nov4asloop**

Prevents routes with looped AS paths from being advertised to version 4 external peers. This can be useful to avoid advertising such routes to peers that would incorrectly forward the routes on to version 3 neighbors.

### **logupdown**

Causes a message to be logged via the syslog mechanism whenever a BGP peer enters or leaves the ESTABLISHED state.

### **traceoptions** *trace\_options*

Specifies the tracing options for this BGP neighbor. By default, these are inherited from group or BGP global trace options.(See Trace Statements and the BGP specific tracing options below.)

## **Tracing options**

**Note:** The state option works with BGP, but does not provide true state transition information.

Packet tracing options (which may be modified with detail, send, and recv):

| Item             | Description                                                                |
|------------------|----------------------------------------------------------------------------|
| <b>packets</b>   | All BGP packets.                                                           |
| <b>open</b>      | BGP OPEN packets that are used to establish a peer relationship.           |
| <b>update</b>    | BGP UPDATE packets that are used to pass network reachability information. |
| <b>keepalive</b> | BGP KEEPALIVE packets that are used to verify peer reachability.           |

## **The BGP4+ Statement**

The options are the same for BGP4+ as they are for **bgp** but all the addresses will be IPv6 addresses.

The syntax is:

```
bgp4+ yes | no | on | off
[{
 preference <preference> ;
 defaultmetric <metric> ;
 traceoptions <trace_options> ;
 group type (external peeras <autonomous_system>)
 | (internal peeras <autonomous_system>)
 | (igp peeras <autonomous_system> proto <proto>)
 | (routing peeras <autonomous_system> proto <proto>
 interface <interface_list>)
 | (test peeras <autonomous_system>)
 {
 allow {
 <network>
 <network> masklen <number>
 all
 host <IPv6 host address>
 } ;
 peer <IPv6 host address>
 [metricout <metric>]
```

```

[localas <autonomous_system>]
[nogedefault]
[gateway <gateway>]
[preference <preference>]
[preference2 <preference>]
[lcladdr <local_address>]
[holdtime <time>]
[version <number>]
[passive]
[sendbuffer <number>]
[recvbuffer <number>]
[indelay <time>]
[outdelay <time>]
[keep [all | none]]
[analretentive]
[noauthcheck]
[noaggregatorid]
[keepalivesalways]
[v3asloopokay]
[nov4asloop]
[logupdown]
[ttl <ttl>]
[traceoptions <trace_options>]
;
}
}] ;

```

## The ICMP Statement

```

icmp {
 traceoptions trace_options ;
}

```

**Item**

**traceoptions** *trace\_options*;

**Description**

Specifies the tracing options for ICMP. (See Trace Statements and the ICMP specific tracing options below.)

### Tracing options

Packet tracing options (which may be modified with detail and recv):

| <b>Item</b>            | <b>Description</b>                                                                                                                                   |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>packets</b>         | All ICMP packets received.                                                                                                                           |
| <b>redirect</b>        | Only ICMP REDIRECT packets received.                                                                                                                 |
| <b>routerdiscovery</b> | Only ICMP ROUTER DISCOVERY packets received.                                                                                                         |
| <b>info</b>            | Only ICMP informational packets, which include mask request/response, info request/response, echo request/response, and time stamp request/response. |
| <b>error</b>           | Only ICMP error packets, which include time exceeded, parameter problem, unreachable and source quench.                                              |

## The SNMP Statement

The Simple Network Management Protocol (SNMP) is a not a routing protocol but a network management protocol. The **snmp** statement controls whether **gated.conf** tries to contact the SNMP Multiplexing daemon to register supported variables. The SNMP daemon, **smuxd**, must be run independently. The **snmp** statement only controls whether **gated.conf** keeps the management software apprised of its status.

**gated.conf** communicates with the SNMP daemon via the SMUX protocol that is described in RFC 1227.

```

snmp yes | no | on | off
[{
 port port ;
 debug;
 traceoptions traceoptions;
}] ;

```

Reporting is enabled by specifying yes or on and disabled with no or off. The default is on.

| Item                                     | Description                                                                                                                                                                                               |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>port</b> <i>port</i>                  | By default, the SMUX daemon listens for requests on port 199. The <b>gated.conf</b> subroutine can be configured to try to contact the SMUX daemon on a different port by explicitly specifying the port. |
| <b>debug</b>                             | Specifying this option enables debugging of the ISODE SMUX code. The default is debugging disabled.                                                                                                       |
| <b>traceoptions</b> <i>trace_options</i> | Specifies the tracing options for SMUX. (See Trace Statements and the SMUX specific tracing options below.)                                                                                               |

## Tracing options

There are no SNMP-specific trace options. The detail, send, and recv options are not supported.

| Item            | Description                                                               |
|-----------------|---------------------------------------------------------------------------|
| <b>receive</b>  | SNMP requests received from the SMUX daemon and the associated responses. |
| <b>register</b> | Protocol requests to register variables.                                  |
| <b>resolve</b>  | Protocol requests to resolve variable names.                              |
| <b>trap</b>     | SNMP trap requests from protocols.                                        |

## Static Statements

Static statements define the static routes used by the **gated** daemon. A single static statement can specify any number routes. The static statements occur after protocol statements and before control statements in the **gated.conf** file. Any number of static statements may be specified, each containing any number of static route definitions. These routes can be overridden by routes with better preference values.

```

static {
 (host host) | default |
 (network [(mask mask) | (masklen number)])
 gateway gateway_list
 [interface interface_list]
 [preference preference]
 [retain]
 [reject]
 [blackhole]
 [noinstall] ;
 (network [(mask mask) | (masklen number)])
 interface interface
 [preference preference]
 [retain]
 [reject]
 [blackhole]
 [noinstall] ;
} ;

```

```
host host gateway gateway_list (network [(mask mask) | (masklen number)]) default gateway gateway_list
```

This is the most general form of the static statement. It defines a static route through one or more gateways. Static routes are installed when one or more of the gateways listed are available on directly attached interfaces.

Parameters for static routes are:

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>interface</b> <i>interface_list</i> | When this parameter is specified, gateways are only considered valid when they are on one of these interfaces. See the section on <i>interface_list</i> specification for the description of the <i>interface_list</i> .                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>preference</b> <i>preference</i>    | This option selects the preference of this static route. The preference controls how this route competes with routes from other protocols. The default preference is 60.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>retain</b>                          | Normally the <b>gated</b> daemon removes all routes except interface routes from the kernel forwarding table during a graceful shutdown. The <b>retain</b> option may be used to prevent specific static routes from being removed. This is useful to ensure that some routing is available when <b>gated</b> is not running. Instead of forwarding a packet like a normal route, <b>reject</b> routes cause packets to be dropped and unreachable messages to be sent to the packet originators. Specifying this option causes this route to be installed as a <b>reject</b> route. Not all kernel forwarding engines support <b>reject</b> routes. |
| <b>reject</b>                          | A <b>blackhole</b> route is the same as a <b>reject</b> route except that unreachable messages are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>blackhole</b>                       | A <b>blackhole</b> route is the same as a <b>reject</b> route except that unreachable messages are not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>noinstall</b>                       | Normally the route with the lowest preference is installed in the kernel forwarding table and is the route exported to other protocols. When <b>noinstall</b> is specified on a route, it will not be installed in the kernel forwarding table when it is active, but it will still be eligible to be exported to other protocols.                                                                                                                                                                                                                                                                                                                   |

```
(network [(mask mask) | (masklen number)]) interface interface
```

This form defines a static interface route that is used for primitive support of multiple network addresses on one interface. The **preference**, **retain**, **reject**, **blackhole** and **noinstall** options are the same as described above.

## The Import Statement

Importation of routes from routing protocols and installation of the routes in the **gated** daemon's routing database is controlled by **import** statements. The format of an **import** statement varies depending on the source protocol.

## Specifying preferences

In all cases, one of two keywords may be specified to control how routes compete with other protocols:

```
restrict
preference preference
```

| Item                                | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>restrict</b>                     | Specifies that the routes are not desired in the routing table. In some cases, this means that the routes are not installed in the routing table. In others, it means that they are installed with a negative preference; this prevents them from becoming <i>active</i> so they will not be installed in the forwarding table, or exported to other protocols.     |
| <b>preference</b> <i>preference</i> | Specifies the preference value used when comparing this route to other routes from other protocols. The route with the lowest preference available at any given route becomes the <i>active</i> route, is installed in the forwarding table, and is eligible to be exported to other protocols. The default preferences are configured by the individual protocols. |

## Route Filters

All the formats allow route filters as shown below. See the section on route filters for a detailed explanation of how they work. When no route filtering is specified (that is, when **restrict** is specified on the first line of a statement), all routes from the specified source will match that statement. If any filters are specified, only routes that match the specified filters will be imported. Put differently, if any filters are specified, an all **restrict**; is assumed at the end of the list.

```
network [exact | refines]
network mask mask [exact | refines]
network masklen number [exact | refines]
default
host host
```

## Importing Routes from BGP and EGP

```
import proto bgp | EGP autonomous_system autonomous_system
 restrict ;
import proto bgp | EGP autonomous_system autonomous_system
 [preference preference] {
 route_filter [restrict | (preference preference)] ;
 } ;

import proto bgp aspath aspath_regexp
 origin any | ([IGP] [EGP] [incomplete])
 restrict ;
import proto bgp aspath aspath_regexp
 origin any | ([IGP] [EGP] [incomplete])
 [preference preference] {
 route_filter [restrict | (preference preference)] ;
 } ;
```

EGP importation may be controlled by autonomous system.

BGP also supports controlling propagation by the use of AS path regular expressions, which are documented in the section on Matching AS paths.

**Note:** EGP and BGP versions 2 and 3 only support the propagation of *natural* networks, so the host and default route filters are meaningless. BGP version 4 supports the propagation of any destination along with a *contiguous* network mask.

EGP and BGP both store any routes that were rejected implicitly by not being mentioned in a route filter, or explicitly with the **restrict** keyword in the routing table with a negative preference. A negative preference prevents a route from becoming active, which prevents it from being installed in the forwarding table, or exported to other protocols. This alleviates the need to break and re-establish a session upon reconfiguration if importation policy is changed.

## Importing Routes from RIP, HELLO and Redirects

```
import proto rip | hello | redirect
 [(interface interface_list) | (gateway gateway_list)]
 restrict ;
import proto rip | hello | redirect
 [(interface interface_list) | (gateway gateway_list)]
 [preference preference] {
 route_filter [restrict | (preference preference)] ;
}
;
```

The importation of RIP, HELLO, and Redirect routes may be controlled by any of protocol, source interface, and source gateway. If more than one is specified, they are processed from most general (protocol) to most specific (gateway).

RIP and HELLO don't support the use of preference to choose between routes of the same protocol. That is left to the protocol metrics. These protocols do not save routes that were rejected since they have short update intervals.

## Importing Routes from OSPF

```
import proto ospfase [tag ospf_tag] restrict ;
import proto ospfase [tag ospf_tag]
 [preference preference] {
 route_filter [restrict | (preference preference)] ;
}
;
```

Due to the nature of OSPF, only the importation of ASE routes may be controlled. OSPF intra- and inter-area routes are always imported into the gated routing table with a preference of 10. If a tag is specified, the import clause will only apply to routes with the specified tag.

It is only possible to restrict the importation of OSPF ASE routes when functioning as an AS border router. This is accomplished by specifying an **export ospfase** clause. Specification of an empty export clause may be used to restrict importation of ASEs when no ASEs are being exported.

Like the other interior protocols, preference can not be used to choose between OSPF ASE routes, that is done by the OSPF costs. Routes that are rejected by policy are stored in the table with a negative preference.

## The Export Statement

The import statement controls routes received from other systems that are used by the **gated** daemon, and the export statement controls which routes are advertised by the **gated** daemon to other systems. Like the import statement, the syntax of the export statement varies slightly per protocol. The syntax of the export statement is similar to the syntax of the import statement, and the meanings of many of the parameters are identical. The main difference between the two is that while route importation is just controlled by source information, route exportation is controlled by both destination and source.

The outer portion of a given export statement specifies the destination of the routing information you are controlling. The middle portion restricts the sources of importation that you wish to consider And the innermost portion is a route filter used to select individual routes.

## Specifying Metrics

The most specific specification of a metric is the one applied to the route being exported. The values that may be specified for a metric depend on the destination protocol that is referenced by this export statement.

```
restrict
metric metric
```

| Item          | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| restrict      | Specifies that nothing should be exported. If specified on the destination portion of the export statement, it specifies that nothing at all should be exported to this destination. If specified on the source portion, it specifies that nothing from this source should be exported to this destination. If specified as part of a route filter, it specifies that the routes matching that filter should not be exported. |
| metric metric | Specifies the metric to be used when exporting to the specified destination.                                                                                                                                                                                                                                                                                                                                                  |

## Route Filters

All the formats allow route filters as shown below. See the section on route filters for a detailed explanation of how they work. When no route filtering is specified (that is, when restrict is specified on the first line of a statement), all routes from the specified source will match that statement. If any filters are specified, only routes that match the specified filters will be exported. Put differently, if any filters are specified, an all restrict ; is assumed at the end of the list.

```
network [exact | refines]
network mask mask [exact | refines]
network masklen number [exact | refines]
default
host host
```

## Specifying the Destination

As mentioned above, the syntax of the export statement varies depending on the protocol to which it is being applied. One thing that applies in all cases is the specification of a metric. All protocols define a default metric to be used for routes being exported, in most cases this can be overridden at several levels of the export statement.

The specification of the source of the routing information being exported (the export\_list) is described below.

### Exporting to EGP and BGP

```
export proto bgp | EGP as autonomous system
 restrict ;
export proto bgp | EGP as autonomous system
 [metric metric] {
 export_list ;
 } ;
```

Exportation to EGP and BGP is controlled by autonomous system, the same policy is applied to all routers in the AS.

EGP metrics range from 0 to 255 inclusive with 0 being the most attractive.

BGP metrics are 16 bit unsigned quantities, that is, they range from 0 to 65535 inclusive with 0 being the most attractive.

If no export policy is specified, only routes to attached interfaces will be exported. If any policy is specified, the defaults are overridden. It is necessary to explicitly specify everything that should be exported.

**Note:** EGP and BGP versions 2 and 3 only support the propagation of *natural* networks, so the host and default route filters are meaningless. BGP version 4 supports the propagation of any destination along with a *contiguous* network mask.

## Exporting to RIP and HELLO

```
export proto rip | hello
 [(interface interface_list) | (gateway gateway_list)]
 restrict ;
export proto rip | hello
 [(interface interface_list) | (gateway gateway_list)]
 [metric metric] {
 export_list ;
} ;
```

Exportation to RIP and HELLO is controlled by any of protocol, interface or gateway. If more than one is specified, they are processed from the most general (protocol) to the most specific (gateway).

It is not possible to set metrics for exporting RIP routes into RIP, or exporting HELLO routes into HELLO. Attempts to do this are silently ignored.

If no export policy is specified, RIP and interface routes are exported into RIP and HELLO and interface routes are exported into HELLO. If any policy is specified, the defaults are overridden. It is necessary to explicitly specify everything that should be exports.

RIP version 1 and HELLO assume that all subnets of the shared network have the same subnet mask so they are only able to propagate subnets of that network. RIP version 2 removes that restriction and is capable of propagating all routes when not sending version 1 compatible updates.

To announce routes that specify a next hop of the loopback interface (that is, static and internally generated default routes) via RIP or HELLO, it is necessary to specify the metric at some level in the export clause. For example, just setting a default metric for RIP or HELLO is not sufficient. This is a safeguard to verify that the announcement is intended.

## Exporting to OSPF

```
export proto ospfase [type 1 | 2] [tag ospf_tag]
 restrict ;
export proto ospfase [type 1 | 2] [tag ospf_tag]
 [metric metric] {
 export_list ;
} ;
```

It is not possible to create OSPF intra- or inter-area routes by exporting routes from the the **gated** daemon routing table into OSPF. It is only possible to export from the **gated** daemon routing table into OSPF ASE routes. It is also not possible to control the propagation of OSPF routes within the OSPF protocol.

There are two types of OSPF ASE routes, *type 1* and *type 2*. See the OSPF protocol configuration for a detailed explanation of the two types. The default type is specified by the *defaults* subclause of the *ospf* clause. This may be overridden by a specification on the *export* statement.

OSPF ASE routes also have the provision to carry a *tag*. This is an arbitrary 32 bit number that can be used on OSPF routers to filter routing information. See the OSPF protocol configuration for detailed information on OSPF tags. The default tag specified by the *ospf defaults* clause may be overridden by a tag specified on the *export* statement.

## Specifying the Source

The export list specifies **export** based on the origin of a route and the syntax varies depending on the source.

### Exporting BGP and EGP Routes

```
proto bgp | EGP autonomous_system autonomous_system
 restrict ;
proto bgp | EGP autonomous_system autonomous_system
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

BGP and EGP routes may be specified by the source autonomous system. All routes may be exported by as path, see the Exporting by AS Path section for more information.

### Exporting RIP and HELLO Routes

```
proto rip | hello
 [(interface interface_list) | (gateway gateway_list)]
 restrict ;
proto rip | hello
 [(interface interface_list) | (gateway gateway_list)]
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

RIP and HELLO routes may be exported by protocol, source interface, and/or source gateway.

### Exporting OSPF Routes

```
proto ospf | ospfase restrict ;
proto ospf | ospfase [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

Both OSPF and OSPF ASE routes may be exported into other protocols. See below for information on exporting by tag.

### Exporting Routes from Non-routing Protocols

#### Non-routing with Interface

```
proto direct | static | kernel
 [(interface interface_list)]
 restrict ;
proto direct | static | kernel
 [(interface interface_list)]
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

These protocols may be exported by protocol, or by the interface of the next hop. These protocols are:

| Item   | Description                                                                                                                                                                   |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| direct | Routes to directly attached interfaces.                                                                                                                                       |
| static | Static routes specified in a static clause.                                                                                                                                   |
| kernel | Routes learned from the routing socket are installed in the gated routing table with a protocol of <i>kernel</i> . These routes may be exported by referencing this protocol. |

### Non-routing by Protocol

```
proto default | aggregate
 restrict ;
proto default | aggregate
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

These protocols may only be referenced by protocol.

| Item      | Description                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| default   | Refers to routes created by the gendefault option. It is recommended that route generation be used instead.                                                    |
| aggregate | Refers to routes synthesized from other routes when the aggregate and generate statements are used. See the section on Route Aggregation for more information. |

## Exporting by AS Path

```
proto proto | all aspath aspath_regexp
 origin any | ([IGP] [EGP] [incomplete])
 restrict ;
proto proto | all aspath aspath_regexp
 origin any | ([IGP] [EGP] [incomplete])
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

When BGP is configured, all routes are assigned an AS path when they are added to the routing table. For all interior routes, this AS path specifies IGP as the origin and no ASEs in the AS path (the current AS is added when the route is exported). For EGP routes this AS path specifies EGP as the origin and the source AS as the AS path. For BGP routes, the AS path is stored as learned from BGP.

AS path regular expressions are documented in the section on Matching AS paths.

## Exporting by Route Tag

```
proto proto | all tag tag restrict ;
proto proto | all tag tag
 [metric metric] {
 route_filter [restrict | (metric metric)] ;
} ;
```

Both OSPF and RIP version 2 currently support tags; all other protocols always have a tag of zero. The source of exported routes may be selected based on this tag. This is useful when routes are classified by a tag when they are exported into a given routing protocol.

## Route Aggregation

Route aggregation is a method of generating a more general route given the presence of a specific route. It is used, for example, at an autonomous system border to generate a route to a network to be advertised via EGP given the presence of one or more subnets of that network learned via RIP. No aggregation is performed unless explicitly requested in an aggregate statement.

Route aggregation is also used by regional and national networks to reduce the amount of routing information passed around. With careful allocation of network addresses to clients, regional networks can just announce one route to regional networks instead of hundreds.

Aggregate routes are not actually used for packet forwarding by the originator of the aggregate route, only by the receiver (if it wishes).

A slight variation of aggregation is the generation of a route based on the existence of certain conditions. This is sometimes known as the *route of last resort*. This route inherits the next hops and aspath from the contributor specified with the lowest (most favorable) preference. The most common usage for this is to generate a default based on the presence of a route from a peer on a neighboring backbone.

## Aggregation and Generation syntax

```
aggregate default
| (network [(mask mask) | (masklen number)])
[preference preference] [brief] {
proto [all | direct | static | kernel | aggregate | proto]
[(as autonomous system) | (tag tag)
| (aspath aspath_regexp)]
restrict ;
proto [all | direct | static | kernel | aggregate | proto]
[(as autonomous system) | (tag tag)
| (aspath aspath_regexp)]
[preference preference] {
route_filter [restrict | (preference preference)] ;
} ;
} ;

generate default
| (network [(mask mask) | (masklen number)])
[preference preference] {
[(as autonomous system) | (tag tag)
| (aspath aspath_regexp)]
restrict ;
proto [all | direct | static | kernel | aggregate | proto]
[(as autonomous system) | (tag tag)
| (aspath aspath_regexp)]
[preference preference] {
route_filter [restrict | (preference preference)] ;
} ;
} ;
```

Routes that match the route filters are called *contributing* routes. They are ordered according to the aggregation preference that applies to them. If there are more than one contributing routes with the same aggregating preference, the route's own preferences are used to order the routes. The preference of the aggregate route will be that of contributing route with the lowest aggregate preference.

| Item                                | Description                                                                                                                                                                               |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>preference</b> <i>preference</i> | Specifies the preference to assign to the resulting aggregate route. The default preference is 130.                                                                                       |
| <b>brief</b>                        | Used to specify that the AS path should be truncated to the longest common AS path. The default is to build an AS path consisting of SETs and SEQUENCEs of all contributing AS paths.     |
| <b>proto</b> <i>proto</i>           | In addition to the special protocols listed, the contributing protocol may be chosen from among any of the ones supported (and currently configured into) <b>gated</b> .                  |
| <b>as</b> <i>autonomous_system</i>  | Restrict selection of routes to those learned from the specified autonomous system.                                                                                                       |
| <b>tag</b> <i>tag</i>               | Restrict selection of routes to those with the specified tag.                                                                                                                             |
| <b>aspath</b> <i>aspath_regexp</i>  | Restrict selection of routes to those that match the specified AS path.                                                                                                                   |
| <b>restrict</b>                     | Indicates that these routes are not to be considered as contributors of the specified aggregate. The specified protocol may be any of the protocols supported by the <b>gated</b> daemon. |
| <b>route_filter</b>                 | See the section on Route Filters for more detail.                                                                                                                                         |

A route may only contribute to an aggregate route that is more general than itself; it must match the aggregate under its mask. Any given route may only contribute to one aggregate route, which will be the most specific configured, but an aggregate route may contribute to a more general aggregate.

## Route Filters

All the formats allow route filters as shown below. See the section on route filters for a detailed explanation of how they work. When no route filtering is specified (that is, when **restrict** is specified on the first line of a statement), all routes from the specified source will match that statement. If any filters are specified, only routes that match the specified filters will be considered as contributors. Put differently, if any filters are specified, an **all restrict ;** is assumed at the end of the list.

```
network [exact | refines]
network mask mask [exact | refines]
network masklen number [exact | refines]
default
host host
```

## Preference

Preference is the value the **gated** daemon uses to order preference of routes from one protocol or peer over another. Preference can be set in the **gated.conf** configuration file in several different configuration statements.

Preference can be set based on network interface over another, from one protocol over another, or from one remote gateway over another.

Preference may not be used to control the selection of routes within an **IGP**, this is accomplished automatically by the protocol based on metric. Preference may be used to select routes from the same **EGP** learned from different peers or autonomous systems.

Each route has only one preference value associated with it, even though preference can be set at many places in the configuration file. Simply, the last or most specific preference value set for a route is the value used. The preference value is an arbitrarily assigned value used to determine the order of routes to the same destination in a single routing database. The active route is chosen by the lowest preference value.

Some protocols implement a second preference (preference2), sometimes referred to as a tie-breaker.

## Selecting a Route

- The route with the best (numerically smallest) preference is preferred.
- If the two routes have the same preference, the route with the best (numerically smallest) preference<sup>2</sup> (also known as a tie-breaker) is preferred.
- A route learned from a **IGP** is preferred to a route learned from an **EGP**. Least preferred is a route learned indirectly by an **IGP** from an **EGP**.
- If AS path information is available it is used to help determine the most preferred route.
  - A route with an AS path is preferred over one without an AS path.
  - If the AS paths and origins are identical, the route with the lower metric is preferred.
  - A route with an AS path origin of **IGP** is preferred over a route with an AS path origin of **EGP**. Least preferred is an AS path with an **unknown** origin.
  - A route with a shorter AS path is preferred.
- If both routes are from the same protocol and AS, the one with the lowest metric is preferred.
- The route with the lowest numeric next-hop address is used.

## Assigning Preferences

A default preference is assigned to each source from which the **gated** daemon receives routes. Preference values range from 0 to 255 with the lowest number indicating the most preferred route.

The following table summarizes the default preference values for routes learned in various ways. The table lists the statements (some of these are clauses within statements) that set preference, and shows the types of routes to which each statement applies. The default preference for each type of route is listed, and the table notes preference precedence between protocols. The narrower the scope of the statement, the higher precedence its preference value is given, but the smaller the set of routes it affects.

| Preference Of                      | Defined by Statement | Default |
|------------------------------------|----------------------|---------|
| direct connected networks          | interface            | 0       |
| OSPF routes                        | ospf                 | 10      |
| IS-IS level 1 routes               | isis level 1         | 15      |
| IS-IS level 2 routes               | isis level 2         | 18      |
| internally generated default       | gendifault           | 20      |
| redirects                          | redirect             | 30      |
| routes learned via route socket    | kernel               | 40      |
| static routes from config          | static               | 60      |
| ANS SPF (SLSP) routes              | slsp                 | 70      |
| HELLO routes                       | hello                | 90      |
| RIP routes                         | rip                  | 100     |
| point-to-point interface           |                      | 110     |
| routes to interfaces that are down | interfaces           | 120     |
| aggregate/generate routes          | aggregate/generate   | 130     |
| OSPF AS external routes            | ospf                 | 150     |
| BGP routes                         | bgp                  | 170     |
| EGP                                | EGP                  | 200     |

## Sample Preference Specifications

```
interfaces {
 interface 138.66.12.2 preference 10 ;
} ;
rip yes {
 preference 90 ;
} ;
import proto rip gateway 138.66.12.1 preference 75 ;
```

In these statements, the preference applicable to routes learned via RIP from gateway 138.66.12.1 is 75. The last preference applicable to routes learned via RIP from gateway 128.66.12.1 is defined in the accept statement. The preference applicable to other RIP routes is found in the rip statement. The preference set on the interface statement applies only to the route to that interface.

## The Router Discovery Protocol

The Router Discovery Protocol is an IETF standard protocol used to inform hosts of the existence of routers. It is used in place of, or in addition to statically configured default routes in hosts.

The protocol is split into two portions, the *server* portion which runs on routers, and the *client* portion that runs on hosts. The **gated** daemon treats these much like two separate protocols, only one of which may be enabled at a time.

### The Router Discovery Server

The Router Discovery Server runs on routers and announces their existence to hosts. It does this by periodically multicasting or broadcasting a **Router Advertisement** to each interface on which it is enabled. These Router Advertisements contain a list of all the routers addresses on a given interface and their preference for use as default routers.

Initially, these Router Advertisements occur every few seconds, then fall back to every few minutes. In addition, a host may send a **Router Solicitation** to which the router will respond with a unicast Router Advertisement (unless a multicast or broadcast advertisement is due momentarily).

Each Router Advertisement contains an *Advertisement Lifetime* field indicating for how long the advertised addresses are valid. This lifetime is configured such that another Router Advertisement will be sent before the lifetime has expired. A lifetime of zero is used to indicate that one or more addresses are no longer valid.

The Router Advertisements are by default sent to the all-hosts multicast address 224.0.0.1. However, the use of broadcast may be specified. When Router Advertisements are being sent to the all-hosts multicast address, or an interface is configured for the limited-broadcast address 255.255.255.255, all IP addresses configured on the physical interface are included in the Router Advertisement. When the Router Advertisements are being sent to a net or subnet broadcast, only the address associated with that net or subnet is included.

### The Router Discovery Server Statement

```
routerdiscovery server yes | no | on | off [{
 traceoptions trace_options ;
 interface interface_list
 [minadvinterval time]
 [maxadvinterval time]
 [lifetime time]
 ;
 address interface_list
 [advertise] | [ignore]
 [broadcast] | [multicast]
 [ineligible] | [preference preference]
 ;
}] ;
```

#### traceoptions trace\_options

Specifies the Router Discovery tracing options. (See Trace Statements and the Router Discovery specific tracing options below.)

#### interface interface\_list

Specifies the parameters that apply to physical interfaces. Note a slight difference in convention from the rest of the gated daemon, **interface** specifies just physical interfaces (such as en0 and tr0), while **address** specifies protocol (in this case IP) addresses.

Interface parameters are:

**maxadvinterval** *time*

The maximum time allowed between sending broadcast or multicast Router Advertisements from the interface. Must be no less than 4 and no more than 30:00 (30 minutes or 1800 seconds). The default is 10:00 (10 minutes or 600 seconds).

**minadvinterval** *time*

The minimum time allowed between sending unsolicited broadcast or multicast Router Advertisements from the interface. Must be no less than 3 seconds and no greater than **maxadvinterval**. The default is 0.75 \* **maxadvinterval**.

**lifetime** *time*

The lifetime of addresses in a Router Advertisement. Must be no less than **maxadvinterval** and no greater than 2:30:00 (two hours, thirty minutes or 9000 seconds). The default is 3 \* **maxadvinterval**.

**address** *interface\_list*

Specifies the parameters that apply to the specified set of addresses on this physical interface. Note a slight difference in convention from the rest of **gated.conf**; **interface** specifies just physical interfaces (such as *en0* and *tr0*), while **address** specifies protocol (in this case IP) addresses.

**advertise**

Specifies that the specified address(es) should be included in Router Advertisements. This is the default.

**ignore** Specifies that the specified address(es) should not be included in Router Advertisements.

**broadcast**

Specifies that the given address(es) should be included in a broadcast Router Advertisement because this system does not support IP multicasting, or some hosts on attached network do not support IP multicasting. It is possible to mix addresses on a physical interface such that some are included in a broadcast Router Advertisement and some are included in a multicast Router Advertisement. This is the default if the router does not support IP multicasting.

**multicast**

Specifies that the given address(es) should only be included in a multicast Router Advertisement. If the system does not support IP multicasting the address(es) will not be included. If the system supports IP multicasting, the default is to include the address(es) in a multicast Router Advertisement if the given interface supports IP multicasting, if not the address(es) will be included in a broadcast Router Advertisement.

**preference** *preference*

The preferability of the address(es) as a default router address, relative to other router addresses on the same subnet. A 32-bit, signed, twos-complement integer, with higher values meaning more preferable. Note that hex 80000000 may only be specified as **ineligible**. The default is 0.

**ineligible**

Specifies that the given address(es) will be assigned a preference of (hex 80000000) that means that it is not eligible to be the default route for any hosts.

This is useful when the address(es) should not be used as a default route, but are given as the next hop in an ICMP redirect. This allows the hosts to verify that the given addresses are up and available.

## The Router Discovery Client

A host listens for Router Advertisements via the all-hosts multicast address (224.0.0.2), If IP multicasting is available and enabled, or on the interface's broadcast address. When starting up, or when reconfigured, a host may send a few Router Solicitations to the all-routers multicast address, 224.0.0.2, or the interface's broadcast address.

When a Router Advertisement with non-zero lifetime is received, the host installs a default route to each of the advertised addresses. If the preference **ineligible**, or the address is not on an attached interface, the route is marked unusable but retained. If the preference is usable, the metric is set as a function of the preference such that the route with the best preference is used. If more than one address with the same preference is received, the one with the lowest IP address will be used. These default routes are not exportable to other protocols.

When a Router Advertisement with a zero lifetime is received, the host deletes all routes with next-hop addresses learned from that router. In addition, any routers learned from ICMP redirects pointing to these addresses will be deleted. The same will happen when a Router Advertisement is not received to refresh these routes before the lifetime expires.

## The Router Discovery Client Statement

```
routerdiscovery client yes | no | on | off [{
 traceoptions trace_options ;
 preference preference ;
 interface interface_list
 [enable] | [disable]
 [broadcast] | [multicast]
 [quiet] | [solicit]
 ;
}] ;
```

### traceoptions *trace\_options*

Specifies the tracing options for Router Discovery Client. (See Trace Statements and the Router Discovery Client specific tracing options below.)

### preference *preference* ;

Specifies the preference of all Router Discovery default routes. The default is 55.

### interface *interface\_list*

Specifies the parameters that apply to physical interfaces. Note a slight difference in convention from the rest of **gated**, **interface** specifies just physical interfaces (such as `en0` and `tr0`). The Router Discovery Client has no parameters that apply only to interface addresses.

#### enable

Specifies that Router Discovery should be performed on the specified interface(s). This is the default.

#### disable

Specifies that Router Discovery should not be performed on the specified interface(s).

#### broadcast

Specifies that Router Solicitations should be broadcast on the specified interface(s). This is the default if IP multicast support is not available on this host or interface.

#### multicast

Specifies that Router Solicitations should be multicast on the specified interface(s). If IP multicast is not available on this host and interface, no solicitation will be performed. The default is to multicast Router Solicitations if the host and interface support it, otherwise Router Solicitations are broadcast.

- quiet** Specifies that no Router Solicitations will be sent on this interface, even though Router Discovery will be performed.
- solicit** Specifies that initial Router Solicitations will be sent on this interface. This is the default.

## Tracing options

The Router Discovery Client and Server support the state trace flag that traces various protocol occurrences.

| Item  | Description       |
|-------|-------------------|
| state | State transitions |

The Router Discovery Client and Server do not directly support any packet tracing options, tracing of router discovery packets is enabled via the ICMP Statement.

## Route Filtering

Routes are filtered by specifying configuration language that will match a certain set of routes by destination, or by destination and mask. Among other places, route filters are used on `martians`, `import` and `export` statements.

The action taken when no match is found is dependent on the context, for instance `import` and `export` route filters assume an `all reject ;` at the end of a list.

A route will match the most specific filter that applies. Specifying more than one filter with the same destination, mask and modifiers will generate an error.

### Filtering syntax

```

network [exact | refines]
network mask mask [exact | refines]
network masklen number [exact | refines]
all
default
host host

```

These are all the possible formats for a route filter. Not all of these formats are available in all places, for instance the `host` and `default` formats are not valid for `martians`.

In most cases it is possible to specify additional parameters relevant to the context of the filter. For example, on a `martian` statement it is possible to specify the `allow` keyword, on an `import` statement you can specify a preference, and on a `export` you can specify a metric.

**network [ exact | refines ]**

**network mask mask [ exact | refines ]**

**network masklen number [ exact | refines ]**

Matching usually requires both an address and a mask, although the mask is implied in the shorthand forms listed below. These three forms vary in how the mask is specified. In the first form, the mask is implied to be the natural mask of the network. In the second, the mask is explicitly specified. In the third, the mask is specified by the number of contiguous one bits.

If no additional parameters are specified, any destination that falls in the range given by the network and mask is matched, the mask of the destination is ignored. If a *natural* network is specified, the network, any subnets, and any hosts will be match. The two optional modifiers cause the mask of the destination to be considered also:

**exact** This parameter specifies that the mask of the destination must match the supplied mask *exactly*. This is used to match a network, but no subnets or hosts of that network.

**refines**

Specifies that the mask of the destination must be more specified (that is, longer) than the filter mask. This is used to match subnets and/or hosts of a network, but not the network.

**all** This entry matches anything. It is equivalent to:

**0.0.0.0 mask 0.0.0.0**

**default**

Matches the **default** route. To match, the address must be the default address and the mask must be all zeros. This is equivalent to:

**0.0.0.0 mask 0.0.0.0 exact**

**host host**

Matches the specific host. To match, the address must exactly match the specified *host* and the network mask must be a host mask (that is, all ones). This is equivalent to:

**host mask 255.255.255 exact**

## Matching AS Paths

An AS path is a list of autonomous\_systems that routing information has passed through to get to this router, and an indicator of the origin of the AS path. This information can be used to prefer one path to a destination network over another. The primary method for doing this with **gated.conf** is to specify a list of patterns to be applied to AS paths when importing and exporting routes.

Each autonomous system that a route passed through prepends its AS number to the beginning of the AS path.

The origin information details the completeness of AS path information. An origin of **IGP** indicates the route was learned from an interior routing protocol and is most likely complete. An origin of **EGP** indicates the route was learned from an exterior routing protocol that does not support AS paths (EGP, for example) and the path is most likely not complete. When the path information is definitely not complete, an origin of **incomplete** is used.

AS path regular expressions are defined in RFC 1164 section 4.2.

## AS Path Matching Syntax

An AS path is matched using the following syntax:

**aspath aspath\_regex origin any | ( [IGP] [EGP] [incomplete] )**

This specifies that an AS matching the *aspath\_regex* with the specified origin is matched.

## AS Path Regular Expressions

Technically, an AS path regular expression is a regular expression with the alphabet being the set of AS numbers. An AS path regular expression is composed of one or more AS paths expressions. An AS path expressions is composed of AS path terms and AS path operators.

## AS Path Terms

An AS path term is one of the following three objects:

```
autonomous_system
 (aspath_regexp)
```

| Item              | Description                                                                                                                                         |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| autonomous_system | Is any valid autonomous system number, from one through 65534 inclusive.                                                                            |
| .                 | Matches any autonomous system number.                                                                                                               |
| ( aspath_regexp ) | Contains parentheses group subexpressions—an operator, such as * or ? works on a single element or on a regular expression enclosed in parentheses. |

## AS Path Operators

An AS path operator is one of the following:

```
aspath_term {m,n}
aspath_term {m}
aspath_term {m,}
aspath_term *
aspath_term +
aspath_term ?
aspath_term | aspath_term
```

| Item                      | Description                                                                                                                                  |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| aspath_term {m,n}         | a regular expression followed by {m,n} (where m and n are both non-negative integers and m <= n) means at least m and at most n repetitions. |
| aspath_term {m}           | a regular expression followed by {m} (where m is a positive integer) means exactly m repetitions.                                            |
| aspath_term {m,}          | a regular expression followed by {m,} (where m is a positive integer) means m or more repetitions.                                           |
| aspath_term *             | an AS path term followed by * means zero or more repetitions. This is shorthand for {0,}.                                                    |
| aspath_term +             | a regular expression followed by + means one or more repetitions. This is shorthand for {1,}.                                                |
| aspath_term ?             | a regular expression followed by ? means zero or one repetition. This is shorthand for {0,1}.                                                |
| aspath_term   aspath_term | matches the AS term on the left, or the AS term on the right.                                                                                |

## gateways File Format for TCP/IP Purpose

Specifies Internet routing information to the **routed** daemon on a network.

### Description

The **/etc/gateways** file identifies gateways for the **routed** daemon. Ordinarily, the daemon queries the network and builds routing tables. The daemon builds the tables from routing information transmitted by other hosts directly connected to the network. Gateways that the daemon cannot identify through its queries are known as *distant gateways*. Such gateways should be identified in the **gateways** file, which the **routed** daemon reads when it starts.

The general format of an entry (contained on a single line) in the **gateways** file is:

Following is a brief description of each element in an **gateways** file entry:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Destination     | A keyword that indicates whether the route is to a network or a specific host. The two possible keywords are <b>net</b> and <b>host</b> .                                                                                                                                                                                                                                                                                                                           |
| Name1           | The name associated with <i>Destination</i> . The <i>Name1</i> variable can be either a symbolic name (as used in the <i>/etc/hosts</i> or <i>/etc/networks</i> file) or an Internet address specified in dotted-decimal format.                                                                                                                                                                                                                                    |
| gateway         | An indicator that the following string identifies the gateway host.                                                                                                                                                                                                                                                                                                                                                                                                 |
| Name2           | The name or address of the gateway host to which messages should be forwarded.                                                                                                                                                                                                                                                                                                                                                                                      |
| metric          | An indicator that the next string represents the hop count to the destination host or network.                                                                                                                                                                                                                                                                                                                                                                      |
| Value           | The hop count, or number of gateways from the local network to the destination network.                                                                                                                                                                                                                                                                                                                                                                             |
| Type            | A keyword that indicates whether the gateway should be treated as active, passive, or external. The three possible keywords are:                                                                                                                                                                                                                                                                                                                                    |
| <b>active</b>   | An active gateway is treated like a network interface. That is, the gateway is expected to exchange Routing Information Protocol (RIP) information. As long as the gateway is active, information about it is maintained in the internal routing tables. This information is included with any routing information transmitted through RIP. If the gateway does not respond for a period of time, the associated route is deleted from the internal routing tables. |
| <b>passive</b>  | A passive gateway is not expected to exchange RIP information. Information about the gateway is maintained in the routing tables indefinitely and is included with any routing information transmitted through RIP.                                                                                                                                                                                                                                                 |
| <b>external</b> | An external gateway is identified to inform the <b>routed</b> daemon that another routing process will install such a route and that alternative routes to that destination should not be installed. Information about external gateways is not maintained in the internal routing tables and is not transmitted through RIP.<br><b>Note:</b> These routes must be to networks.                                                                                     |

## Examples

1. To specify a route to a network through a gateway host with an entry in the **gateways** file, enter a line in the following format:

```
net net2 gateway host4 metric 4 passive
```

This example specifies a route to a network, net2, through the gateway host4. The hop count metric to net2 is 4 and the gateway is treated as passive.

2. To specify a route to a host through a gateway host with an entry in the **gateways** file, enter a line in the following format:

```
host host2 gateway host4 metric 4 passive
```

This example specifies a route to a host, host2, through the gateway host4. The hop count metric to host2 is 4 and the gateway is treated as passive.

3. To specify a route to a host through an active Internet gateway with an entry in the **gateways** file, enter a line in the following format:

```
host host10 gateway 192.100.11.5 metric 9
active
```

This example specifies a route to a specific host, host10, through the gateway 192.100.11.5. The hop count metric to host10 is 9 and the gateway is treated as active

4. To specify a route to a host through a passive Internet gateway with an entry in the **gateways** file, enter a line in the following format:

```
host host10 gateway 192.100.11.5 metric 9
passive
```

5. To specify a route to a network through an external gateway with an entry in the **gateways** file, enter a line in the following format:

```
net net5 gateway host7 metric 11 external
```

This example specifies a route to a network, net5, through the gateway host7. The hop count metric to net5 is 11 and the gateway is treated as external (that is, it is not advertised through RIP but instead through an unspecified routing protocol).

## hosts File Format for TCP/IP

### Purpose

Defines the Internet Protocol (IP) name and address of the local host and specifies the names and addresses of remote hosts.

### Description

The **/etc/hosts** file contains the Internet Protocol (IP) host names and addresses for the local host and other hosts in the Internet network. This file is used to resolve a name into an address (that is, to translate a host name into its Internet address). When your system is using a name server, the file is accessed only if the name server cannot resolve the host name.

When the local host is using the DOMAIN protocol, the resolver routines query a remote DOMAIN name server before searching this file. In a flat network with no name server, the resolver routines search this file for host name and address data.

Entries in the **hosts** file have the following format:

*Address HostName*

In this entry, *Address* is an IP address specified in either dotted decimal or octal format, and *HostName* is the name of a host specified in either relative or absolute domain name format. If you specify the absolute domain name, the portion of the name preceding the first . (period) has a maximum length of 63 characters and cannot contain blanks. For both formats of the name, the total number of characters cannot exceed 255 characters, and each entry must be contained on one line. Multiple *HostNames* (or aliases) can be specified.

**Note:** Valid host names or alias host names must contain at least one alphabetic character. If you choose to specify a host name or alias that begins with an x followed by any hexadecimal digit (0-f), the host name or alias must also contain at least one additional letter that cannot be expressed as a hexadecimal digit. The system interprets a leading x followed by a hexadecimal digit as the base 16 representation of an address, unless there is at least one character in the host name or alias that is not a hexadecimal digit. Thus, xdeer would be a valid host name, whereas xdee would not.

This file can contain two special case entries that define reserved (or well-known) host names. These host names are:

| Item                     | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| <code>timeserver</code>  | Identifies a remote time server host. This host name is used by the <code>setclock</code> command. |
| <code>printserver</code> | Identifies the default host for receiving print requests.                                          |

In this **hosts** file entry, the *Address* parameter is an IP address specified in either dotted decimal or octal format, and each *HostName* parameter is a host name specified in either relative or absolute domain name format. These never have the full domain name listed; they are always listed as either `printserver` or `timeserver`.

**Note:** The local `/etc/resolv.conf` file defines where DOMAIN name servers are, and the name server file defines where Internet services are available. Although it is not necessary to define well-known hosts in the **hosts** file when using the DOMAIN protocol, it may be useful if they are not defined by your name server.

Entries in this file can be made by using the System Management Interface Tool (SMIT) or the `hostent` command, or by creating and editing the file with an editor.

## Examples

In these examples, the name of the local host is the first line in each **hosts** file. This is to help you identify the host whose file is being displayed. Your host does not have to be defined on the first line of your **hosts** file.

1. The following sample entries might be contained in the **hosts** files for two different hosts on a network that is not running a DOMAIN name server:

Host1

```
185.300.10.1 host1
185.300.10.2 host2
185.300.10.3 host3
185.300.10.4 host4 merlin
185.300.10.5 host5 arthur king
185.300.10.5 timeserver
```

Host 2

```
185.300.10.2 host2
185.300.10.1 host1
185.300.10.3 host3
185.300.10.4 host4 merlin
185.300.10.5 host5 arthur king
```

In this sample network with no name server, the **hosts** file for each host must contain the Internet address and host name for each host on the network. Any host that is not listed cannot be accessed. The host at Internet address 185.300.10.4 in this example can be accessed by either name: host4 or merlin. The host at Internet address 185.300.10.5 can be accessed by any of the names host5, arthur, or king.

2. Following is a sample entry in the **hosts** files for a different host on a DOMAIN network, but the host is not the name server, and the host is keeping some additional host names for a smaller network:

Host 5

```
128.114.1.15 name1.xyz.aus.century.com name1
128.114.1.14 name2.xyz.aus.century.com name2
128.114.1.16 name3.xyz.aus.century.com name3
```

In this sample, host5 is not a name server, but is attached to a DOMAIN network. The hosts file for host5 contains address entries for all hosts in the smaller network, and the DOMAIN data files contain the DOMAIN database. The entries in the host5 **hosts** file that begin with 128.114 indicate that host5 resolves names for hosts on the smaller network.

## **hosts.equiv File Format for TCP/IP**

### **Purpose**

Specifies remote systems that can execute commands on the local system.

### **Description**

The **/etc/hosts.equiv** file, along with any local **\$HOME/.rhosts** files, defines the hosts (computers on a network) and user accounts that can invoke remote commands on a local host without supplying a password. A user or host that is not required to supply a password is considered trusted.

When a local host receives a remote command request, the appropriate local daemon first checks the **/etc/hosts.equiv** file to determine if the request originates with a trusted user or host. For example, if the local host receives a remote login request, the **rlogind** daemon checks for the existence of a **hosts.equiv** file on the local host. If the file exists but does not define the host or user, the system checks the appropriate **\$HOME/.rhosts** file. This file is similar to the **/etc/hosts.equiv** file, except that it is maintained for individual users.

Both files, **hosts.equiv** and **.rhosts** must have permissions denying write access to group and other. If either group or other have write access to a file, that file will be ignored.

Do not give write permission to the **/etc/hosts.equiv** file to group and others. Permissions of the **/etc/hosts.equiv** file should be set to 600 (read and write by owner only).

If a remote command request is made by the root user, the **/etc/hosts.equiv** file is ignored and only the **.rhosts** file is read.

**Note:** Be careful when establishing trusted relationships. Networks that use trusted facilities can be less secure than those that do not.

### **Granting and Denying Trust**

You grant trust from a local host to a remote host or remote user. The local machine's **/etc/hosts.equiv** file contains entries for each trusted host or user. The format of an entry is:

*HostName* [*UserName*]

The *HostName* field specifies the name of the host to trust. The *UserName* field specifies the name of the user on that remote host to trust. The *UserName* field is optional.

You can use the + (plus sign) as a wildcard in either the *HostName* or *UserName* field to grant trust to all users from a particular host or from all hosts that a specific user has an account on. To grant trust to every user on every machine on the network, place a plus sign (+) at the beginning of the file.

**Note:** When granting access through the `/etc/hosts.equiv` file, extreme caution must be used. Lines that include a *UserName*, either as an individual user, a netgroup, or the + (plus sign used as a wildcard character), permit the qualifying users to access the system as any non-root local user.

You deny a host or user trust by omitting them from the `/etc/hosts.equiv` file altogether. By omitting the host or user, you imply they are not trusted. This is the most secure way to deny trust. Otherwise, you can explicitly deny trust to a specific host or user by using the - (minus sign). The format to explicitly deny a host is:

`-HostName`

The format to explicitly deny a specific user from a host is:

`HostName [-UserName]`

### Using NIS with the `/etc/hosts.equiv` file

If your network uses the Network Information Services (NIS), you can use netgroups in place of either the *HostName* or *UserName* field. The system resolves the netgroup depending on which field the netgroup replaces. For example, if you place a netgroup in the *HostName* field, the system resolves the hosts component of the netgroup. If the netgroup appears in the *UserName* field, the user component is resolved. Use the following format to grant trust to a netgroup:

`+@NetGroup`

To deny trust, use the following:

`-@NetGroup`

Refer to the NIS **netgroup** file for more information on netgroups.

### Ordering Entries in the `/etc/hosts.equiv` File

The order of entries in the `/etc/hosts.equiv` file is important. When verifying trust, the system parses the `/etc/hosts.equiv` file from top to bottom. When it encounters an entry that matches the host or user attempting a remote command, the system stops parsing the file and grants or denies trust based on the entry. Any additional entries that appear later in the file are ignored.

## Examples

1. To allow all the users on remote hosts emerald and amethyst to log in to host diamond, enter:

```
emerald
amethyst
```

These entries in diamond's `/etc/hosts.equiv` file allow all the users on emerald and amethyst with local accounts on diamond to remotely log in without supplying a password.

2. To allow only the user gregory to remotely login to diamond from host amethyst, enter:

```
emerald
amethyst gregory
```

This entry in diamond's `/etc/hosts.equiv` file forces all the users on amethyst, except for gregory, to supply a password when remotely logging in to diamond.

3. To grant trust to peter regardless of the host he attempts to execute remote commands from, enter:

```
emerald
amethyst gregory
+ peter
```

This entry in diamond's `/etc/hosts.equiv` file allows peter to execute remote commands on diamond from any host that he has an account on.

4. To allow all hosts in the century netgroup to execute remote commands on host diamond, enter:

```
emerald
amethyst gregory
+ peter
+@century
```

This entry in diamond's **/etc/hosts.equiv** file grants trust to all hosts in the century netgroup. This means that any user with an account on a century host and an account on diamond can execute remote commands on diamond without supplying a password.

5. To allow all the users in the engineers netgroup with accounts on citrine to execute remote commands on host diamond, enter:

```
emerald
amethyst gregory
+ peter
+@century
citrine +@engineers
```

This entry in diamond's **/etc/hosts.equiv** file grants trust to all of netgroup engineers users with an account on citrine.

6. To grant trust to all users with accounts on hosts in the servers netgroup that are users in the sysadmins netgroup, enter:

```
emerald
amethyst gregory
+ peter
+@century
citrine +@engineers
+@servers +@sysadmins
```

This entry in diamond's **/etc/hosts.equiv** file grants trust to any user in the sysadmins netgroup who is remotely executing commands from hosts that are in the servers netgroup.

7. To force an engineers netgroup user lydia who has an account on citrine to use a password while allowing all other engineers users not to, enter:

```
emerald
amethyst gregory
+ peter
+@century
citrine -lydia
citrine +@engineers
+@servers +@sysadmins
```

This entry in diamond's **/etc/hosts.equiv** file grants trust to all of netgroup engineers users, except for lydia, who must supply a password. The order of entries is very important. Recall that the system grants trust based on the first entry it encounters. If the order of the entries appeared as follows:

```
emerald
amethyst gregory
+ peter
+@century
citrine +@engineers
citrine -lydia
+@servers +@sysadmins
```

User lydia, as a member of engineers, would be allowed to execute remote commands on diamond even though a later entry explicitly denies her trust.

## Files

| Item           | Description                                              |
|----------------|----------------------------------------------------------|
| \$HOME/.rhosts | Specifies remote users who can use a local-user account. |

**Related reference:**

- “netgroup File for NIS” on page 168

- “hosts.lpd File Format for TCP/IP”

**Related information:**

- lpd command
- ruser command

## hosts.lpd File Format for TCP/IP

### Purpose

Specifies remote hosts that can print on the local host.

### Description

The **/etc/hosts.lpd** file defines which remote systems are permitted to print on the local system. The remote systems listed in this file do not have the full privileges given to files listed in the **/etc/hosts.equiv** file.

#### Host-Name Field

The **hosts.lpd** file supports the following host-name entries:

```
+
HostName
-HostName
+@NetGroup
-@NetGroup
```

A + (plus sign) signifies that any host on the network can print using the local host. The HostName entry is the name of a remote host and signifies that HostName can print, using the local host. A -HostName entry signifies the host is not allowed to print using the local host. A +@NetGroup or -@NetGroup entry signifies all hosts in the netgroup or no hosts in the netgroup, respectively, are allowed to print using the local host.

The @NetGroup parameter is used by Network Information Service (NIS) for grouping. Refer to the NIS **netgroup** file for more information on netgroups.

Entries in this file can be made using the System Management Interface Tool (SMIT) or the **ruser** command.

**Note:** Comments must be entered on separate lines in the **hosts.lpd** file. Comments should not be entered on lines containing host names.

To implement **hosts.lpd** file changes without restarting the system, use the System Resource Controller (SRC) **refresh** command.

### Examples

1. To allow remote specified hosts to print using a local host, enter:

```
hamlet
lear
prospero
setebos
```

These entries in the local host's **/etc/hosts.lpd** file allow hosts hamlet, lear, prospero, and setebos to print files, using the local host.

2. To prevent a remote host from printing using a local host, enter:

```
-hamlet
```

This entry in the local host's **/etc/hosts.lpd** file prevents host hamlet from printing files, using the local host.

3. To allow all hosts in an NIS netgroup to print using the local host, enter:

```
+@century
```

This entry in the local host's **/etc/hosts.lpd** file allows all hosts in the century netgroup to print files, using the local host. The @ (at sign) signifies the network is using NIS grouping.

Managing and Using Remote Printers and Queues

## hty\_config File Format

### Purpose

Specifies the number of htys to configure on a Network Terminal Accelerator adapter.

### Description

The **/etc/hty\_config** file supplies the **hty\_load** command with information to define ports for a specified device. The System Management Interface Tool (SMIT) writes to this file when **hty** devices are configured, specifying the device by supplying the adapter minor number for the device. Both the number of ports and the device are specified in a three-column table that can have multiple lines.

The Cluster Address column defines the cluster controller's network address. For the boards, the cluster address should be set to 1. Any other value may cause unpredictable results.

After you have configured the Network Terminal Accelerator adapter with SMIT, the **hty\_config** file appears similar to the following:

| Adapter<br>minor # | Cluster<br>address | Number<br>of ports |
|--------------------|--------------------|--------------------|
| 0                  | 1                  | 256                |
| 1                  | 1                  | 700                |
| 2                  | 1                  | 85                 |

In this example, the host has three adapters, the first of which is configured for 256 **hty** devices, the second for 700, and the third for 85.

[hty\\_load command](#)

## inetd.conf File Format for TCP/IP

### Purpose

Defines how the **inetd** daemon handles Internet service requests.

### Description

The **/etc/inetd.conf** file is the default configuration file for the **inetd** daemon. This file enables you to specify the daemons to start by default and supply the arguments that correspond to the desired style of functioning for each daemon. This file is part of TCP/IP in Network Support Facilities.

If you change the **/etc/inetd.conf** file, run the **refresh -s inetd** or **kill -1 InetdPID** command to inform the **inetd** daemon of the changes to its configuration file. The **inetd.conf** file specifies which daemons start by default and supplies arguments determining the style of functioning for each daemon.

The following daemons are controlled by the **inetd** daemon:

- **comsat**
- **ftpd**
- **telnetd**
- **rshd**
- **rlogind**
- **rexecd**
- **fingerd**
- **tftpd**
- **talkd**
- **uucpd**

The **ftpd**, **rlogind**, **rexecd**, **rshd**, **talkd**, **telnetd**, and **uucpd** daemons are started by default. The **tftpd**, **fingerd**, and **comsat** daemons are not started by default unless they are uncommented in the **/etc/inetd.conf** file.

### Service Requests

The following Internet service requests are supported internally by the **inetd** daemon and are generally used for debugging:

| Item    | Description                                                         |
|---------|---------------------------------------------------------------------|
| ECHO    | Returns data packets to a client host.                              |
| DISCARD | Discards received data packets.                                     |
| CHARGEN | Discards received data packets and sends predefined or random data. |
| DAYTIME | Sends the current date and time in user-readable form.              |
| TIME    | Sends the current date and time in machine-readable form.           |

The **inetd** daemon reads its configuration file only when the **inetd** daemon starts, when the **inetd** daemon receives a **SIGHUP** signal, or when the SRC **refresh -s inetd** command is entered. Each line in the **inetd** configuration file defines how to handle one Internet service request only.

Each line is of the form:

*ServiceName* *SocketType* *ProtocolName* *Wait/NoWait* *UserName* *ServerPath* *ServerArgs*

These fields must be separated by spaces or tabs and have the following meanings:

| Item                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ServiceName</i>     | Contains the name of an Internet service defined in the <b>/etc/services</b> file. For services provided internally by the <b>inetd</b> daemon, this name must be the official name of the service. That is, the name must be identical to the first entry on the line that describes the service in the <b>/etc/services</b> file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>SocketType</i>      | Contains the name for the type of socket used for the service. Possible values for the <i>SocketType</i> parameter are:<br><br><b>stream</b> Specifies that a stream socket is used for the service.<br><b>dgram</b> Specifies that a datagram socket is used for the service<br><b>sunrpc_tcp</b> Specifies that a Sun remote procedure call (RPC) socket is used for the service, over a stream connection.<br><b>sunrpc_udp</b> Specifies that a Sun RPC socket is used for the service, over a datagram connection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>ProtocolName</i>    | Contains the name of an Internet protocol defined in the <b>/etc/protocols</b> file. For example, use the <b>tcp</b> value for a service that uses TCP/IP and the <b>udp</b> value for a service that uses the User Datagram Protocol (UDP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>Wait/NoWait/SRC</i> | Contains either the <b>wait</b> , the <b>nowait</b> , or the <b>SRC</b> instruction for datagram sockets and the <b>nowait</b> instruction for stream sockets. The <i>Wait/NoWait/SRC</i> field determines whether the <b>inetd</b> daemon waits for a datagram server to release the socket before continuing to listen at the socket. The <b>SRC</b> instruction works like <b>wait</b> , but instead of forking and waiting for the child to die, it does a <b>startsrc</b> on the subsystem and stores information about the starting of the service. When the service is removed from the <b>inetd.conf</b> file and <b>inetd</b> is restarted, the service then has a <b>stopsrc</b> issued to the service to stop it. If <b>!DEBUG[=level]</b> is specified after <b>wait</b> or <b>nowait</b> , the <b>SO_DEBUG</b> socket debugging flag will be turned on for this service. If <i>level</i> is specified, the trace level is set to the specified level; otherwise the level is set to <b>normal</b> . Valid values for <i>level</i> are <b>min</b> , <b>normal</b> , or <b>detail</b> . |
| <i>UserName</i>        | Specifies the user name that the <b>inetd</b> daemon should use to start the server. This variable allows a server to be given less permission than the root user.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>ServerPath</i>      | Specifies the full path name of the server that the <b>inetd</b> daemon should execute to provide the service. For services that the <b>inetd</b> daemon provides internally, this field should be internal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>ServerArgs</i>      | Specifies the command line arguments that the <b>inetd</b> daemon should use to execute the server. The maximum number of arguments is five. The first argument specifies the name of the server used. If the <i>SocketType</i> parameter is <b>sunrpc_tcp</b> or <b>sunrpc_udp</b> , the second argument specifies the program name and the third argument specifies the version of the program. For services that the <b>inetd</b> daemon provides internally, this field should be empty.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Examples

The following are example entries in the **/etc/inetd.conf** file for an **inetd** daemon that:

- Uses the **ftpd** daemon for servicing **ftp** requests
- Uses the **talkd** daemon for **ntalk** requests
- Uses the **telnetd** daemon for telnet requests, sets the **SO\_DEBUG** flag for sockets used for this service, and sets the trace level for these sockets to normal.
- Provides time requests internally.

```
ftp;stream tcp nowait root /usr/sbin/ftpd ftpd
ntalk dgram udp wait root /usr/sbin/talkd talkd
telnet stream tcp6 nowait !DEBUG root /usr/sbin/telnetd telnetd -a
time stream tcp nowait root internal
time dgram udp wait root internal
```

## Files

| Item           | Description                                                   |
|----------------|---------------------------------------------------------------|
| etc/services   | Defines the sockets and protocols used for Internet services. |
| /etc/protocols | Defines the Internet protocols used on the local host.        |

## Lastlog File Format

### Purpose

Defines the last login attributes for users.

### Description

The /etc/security/lastlog file is an ASCII file that contains stanzas with the last login attributes for users. Each stanza is identified by a user name and contains attributes in the *Attribute=Value* form. Each attribute is ended by a new-line character, and each stanza is ended by an additional new-line character.

Each stanza can have the following attributes:

| Item                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| time_last_login              | Specifies the number of seconds since the epoch (00:00:00 GMT, January 1, 1970) since the last successful login. The value is a decimal integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| tty_last_login               | Specifies the terminal on which the user last logged in. The value is a character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| host_last_login              | Specifies the host from which the user last logged in. The value is a character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| unsuccessful_login_count     | Specifies the number of unsuccessful login attempts since the last successful login. The value is a decimal integer. This attribute works in conjunction with the user's loginretries attribute, specified in the /etc/security/user file, to lock the user's account after a specified number of consecutive unsuccessful login attempts. Once the user's account is locked, the user will not be able to log in until the system administrator resets the user's unsuccessful_login_count attribute to be less than the value of loginretries. To do this, enter the following:<br><br>chsec -f /etc/security/lastlog -s username -a \<br>unsuccessful_login_count=0 |
| time_last_unsuccessful_login | Specifies the number of seconds since the epoch (00:00:00 GMT, January 1, 1970) since the last unsuccessful login. The value is a decimal integer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| tty_last_unsuccessful_login  | Specifies the terminal on which the last unsuccessful login attempt occurred. The value is a character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| host_last_unsuccessful_login | Specifies the host from which the last unsuccessful login attempt occurred. The value is a character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

All user database files should be accessed through the system commands and subroutines defined for this purpose. Access through other commands or subroutines may not be supported in future releases.

The **mkuser** command creates a user stanza in the **lastlog** file. The attributes of this user stanza are initially empty. The field values are set by the **login** command as a result of logging in to the system. The **lsuser** command displays the values of these attributes; the **rmuser** command removes the user stanza from this file, along with the user account.

## Security

Access Control: This command should grant read (r) access to the root user, members of the security group, and others consistent with the security policy for the system. Only the root user should have write (w) access.

## Examples

A typical stanza is similar to the following example for user bck:

```
bck:
 time_last_unsuccessful_login = 732475345
 tty_last_unsuccessful_login = tty0
 host_last_unsuccessful_login = waterski
 unsuccessful_login_count = 0
 time_last_login = 734718467
 tty_last_login = lft/0
 host_last_login = waterski
```

## Files

| Item                  | Description                                    |
|-----------------------|------------------------------------------------|
| /etc/security/lastlog | Specifies the path to the <b>lastlog</b> file. |
| /etc/group            | Contains the basic attributes of groups.       |
| /etc/security/group   | Contains the extended attributes of groups.    |
| /etc/passwd           | Contains the basic attributes of users.        |
| /etc/security/passwd  | Contains password information.                 |
| /etc/security/environ | Contains the environment attributes of users.  |
| /etc/security/user    | Contains the extended attributes of users.     |
| /etc/security/limits  | Contains the process resource limits of users. |

## ldap.cfg File Format

### Purpose

The **secldapclntd** LDAP client side daemon configuration file.

### Description

The **/etc/security/ldap/ldap.cfg** file contains information for the **secldapclntd** daemon to start and function properly as well as information for fine tuning the daemon's performance. The **/etc/security/ldap/ldap.cfg** file is updated by the **mksecldap** command at client setup.

The **/etc/security/ldap/ldap.cfg** file may contain the following fields:

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ldapservers</i>      | Specifies a comma separated list of Lightweight Directory Access Protocol (LDAP) Security Information Servers. These servers can either be the primary server or the replica of the primary server. The first server in the list has the highest priority.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>binddn</i>           | Specifies the distinguished name (DN) LDAP used to bind to the LDAP Security Information Server(s).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>bindpwd</i>          | Specifies the password for the <i>binddn</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>authtype</i>         | Specifies the authentication mechanism to use. Valid values are <b>unix_auth</b> and <b>ldap_auth</b> . The default is <b>unix_auth</b> . <ul style="list-style-type: none"> <li>• <b>unix_auth</b> - Retrieves the user password from LDAP and authenticate the user locally.</li> <li>• <b>ldap_auth</b> - Binds to the LDAP server as the authenticating user in order to authenticate.<br/><b>Note:</b> Password will be sent in clear text to the LDAP server for <b>ldap_auth</b> authentication mechanism. Use of SSL is strongly encouraged.</li> </ul>                                                                                                                                                                              |
| <i>useSSL</i>           | Specifies whether to use the SSL communication. Valid values are <b>yes</b> , <b>SSL</b> , <b>TLS</b> , <b>NONE</b> and <b>no</b> . The default value is <b>no</b> .<br><b>Note:</b> You will need the SSL key and the password to the key to enable this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>ldapsslkeyf</i>      | Specifies the full path of the SSL or TLS key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>ldapsslkeypwd</i>    | Specifies the password of the SSL or TLS key.<br><b>Note:</b> Comment out this line to use stashed password. The password stash file must reside in the same directory as the SSL, or TLS key, and must have the same name as the key file but with an extension of <b>.sth</b> instead of <b>.kdb</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>useKRB5</i>          | Specifies whether to use Kerberos for the initial bind to the server. Valid values are <b>yes</b> or <b>no</b> . The default is <b>no</b> .<br><b>Note:</b> The Kerberos principal, key path and kinit command directory are required to enable this feature. If Kerberos bind is enabled then the <i>binddn</i> and <i>bindpwd</i> are not required.                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>krbprincipal</i>     | Specifies the Kerberos principal used to bind to the server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>krbkeypath</i>       | Specifies the path to the kerberos keytab. The default is <b>/etc/security/ldap krb5.keytab</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>krbcmddir</i>        | Specifies the directory that contains the Kerberos <b>kinit</b> command. The default is <b>/usr/krb5/bin/</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>pwdalgorithm</i>     | Specifies the password encryption algorithm used for the <b>unix_auth</b> mode. The <b>ldap_auth</b> mode ignores this attribute. Valid value is either <b>crypt</b> or <b>system</b> . The default value is <b>crypt</b> . <ul style="list-style-type: none"> <li><b>crypt</b> Specifies the legacy crypt() (DES) algorithm.</li> <li><b>system</b> Specifies to use the system-wide password algorithm configured in the <b>/etc/security/login.cfg</b> file. To use the system-wide password algorithm, the LDAP server's password encryption must be disabled to avoid double encryption. Double encryption can make the password unusable. Ensure that all clients of the LDAP server understand the algorithm that is used.</li> </ul> |
| <i>userattrmappath</i>  | Specifies the full path to the AIX-LDAP attribute map for users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>groupattrmappath</i> | Specifies the full path to the AIX-LDAP attribute map for groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>idattrmappath</i>    | Specifies the full path to the AIX-LDAP attribute map for IDs. These IDs are used by the <b>mkuser</b> command when creating LDAP users.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>userbasedn</i>       | Specifies the user base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>groupbasedn</i>      | Specifies the group base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>idbasedn</i>         | Specifies the ID base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>hostbasedn</i>       | Specifies the host base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>servicebasedn</i>    | Specifies the service base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>protocolbasedn</i>   | Specifies the protocol base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>networkbasedn</i>    | Specifies the network base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>netgroupbasedn</i>   | Specifies the netgroup base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>rpcbasedn</i>        | Specifies the RPC base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>aliasbasedn</i>      | Specifies the alias base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>automountbasedn</i>  | Specifies the automount base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>bootparambasedn</i>  | Specifies the bootparams base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>etherbasedn</i>      | Specifies the ether base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>authbasedn</i>           | Specifies the authorizations base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>rolebasedn</i>           | Specifies the roles base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>privcmdbasedn</i>        | Specifies the privileged commands base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>privdebasedn</i>         | Specifies the privileged devices base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>priofilebasedn</i>       | Specifies the privileged files base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>domainbasedn</i>         | Specifies the domain base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>domobjbasedn</i>         | Specifies the domain object base DN. For more information, see Detailed information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>tsddatbasedn</i>         | Specifies the file's Trusted Signature Database base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>tepoliciesbasedn</i>     | Specifies the machine's trusted execution policies base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>userclasses</i>          | Specifies a comma-separated list of object classes that are used for the user entry. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>groupclasses</i>         | Specifies a comma-separated list of object classes that are used for the group entry. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>ldapversion</i>          | Specifies the LDAP server protocol version. Default is 3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>ldapport</i>             | Specifies the port on which the LDAP server listens to. The default value is 389. Also, TLS use this port as default port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>ldapsslport</i>          | Specifies the SSL port on which the LDAP server listens. The default value is 636.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>followalias</i>          | Specifies whether to follow aliases. Valid values are NEVER, SEARCHING, FINDING, and ALWAYS. Default is NEVER.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>usercachesize</i>        | Specifies the user cache size. Valid values are 100 - 65536 entries. The default value is 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>groupcachesize</i>       | Specifies the group cache size. Valid values are 10 - 65536 entries. The default value is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>cachetimeout</i>         | Specifies the cache TTL (time to live) for users and groups. Value must be >=0 seconds. Default is 300. Set to 0 to disable caching.<br><b>Note:</b> The <i>cachetimeout</i> field is a deprecated attribute. Please use the <i>usercachetimeout</i> and <i>groupcachetimeout</i> attributes instead.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>usercachetimeout</i>     | Specifies the cache TTL (time to live) for users. Value must be >= 0 seconds. Default is 300. Set to 0 to disable user caching. When specified, this value overrides the <i>cachetimeout</i> setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>groupcachetimeout</i>    | Specifies the cache TTL (time to live) for groups. Value must be >= 0 seconds. Default is 300. Set to 0 to disable group caching. When specified, this value overrides the <i>cachetimeout</i> setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>ldapsizelimit</i>        | Specifies the maximum entries to be requested to the ldap server in an ALL query. Default is 0 (no limit). If the <i>ldapsizelimit</i> is greater than the server size limit, the server size limits the number of entries returned. Setting the <i>ldapsizelimit</i> to a lower number increases the performance of some commands. For example, the <b>lsuser -R LDAP ALL</b> command.                                                                                                                                                                                                                                                                                                                                                       |
| <i>heartbeatinterval</i>    | Specifies the interval in seconds that the client contacts the server for server status. Valid values are 60 - 3,600 seconds. Default is 300.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>numberofthread</i>       | Specifies the number of threads for the <b>secldapclntd</b> daemon. Valid values are 1 - 256. Default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>nsorder</i>              | Specifies the order of host name resolution by the <b>secldapclntd</b> daemon. The default order is <b>dns, nis, local</b> . For more information about valid resolvers, see TCP/IP Name Resolution.<br><b>Note:</b> Do not use <b>nis_ldap</b> , because it could result in the <b>secldapclntd</b> daemon hang.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>searchmode</i>           | Specifies the set of user and group attributes to be retrieved. This attribute is intended for use for performance reasons. The AIX commands may not be enabled to support all non-OS attributes. Valid values are <b>ALL</b> and <b>OS</b> . The default is <b>ALL</b> . <ul style="list-style-type: none"> <li>• <b>ALL</b> - Retrieve all attributes of an entry.</li> <li>• <b>OS</b> - Retrieve only the operating system required attributes of an entry. Non-OS attributes like telephone number, binary images etc. will not be returned.</li> </ul> <b>Note:</b> Only use <b>OS</b> when entries have many non-OS required attributes or attributes with large value, e.g. binary data, to reduce sorting effort by the LDAP server. |
| <i>defaultentrylocation</i> | Specifies the location of the default entry. Valid values are <b>ldap</b> and <b>local</b> . The default is <b>ldap</b> . <ul style="list-style-type: none"> <li><b>ldap</b> - Use the default entry in LDAP for all attribute default values.</li> <li><b>local</b> - Use the default stanza from local <b>/etc/security/user</b> file for all attribute default values.</li> </ul>                                                                                                                                                                                                                                                                                                                                                          |

| Item                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ldaptimeout</i>          | Specifies the timeout period in seconds for LDAP client requests to the server. This value determines how long the client will wait for a response from the LDAP server. Valid range is 0 - 3600 (1 hour). Default is 60 seconds. Set this value to 0 to disable the timeout.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>connectionsperserver</i> | Specifies the maximum number of connections to the LDAP server. If the specified value is greater than the value in the <i>numberofthread</i> field, the <b>secldapclntd</b> daemon uses the value of the <i>numberofthread</i> field instead. The <b>secldapclntd</b> daemon starts with one connection and dynamically adds new connections at high LDAP request demand into the <i>connectionsperserver</i> field, and closes the idle connections at low demand. The valid value of this field ranges from 1 through 100. The default value is 10.                                                                                                                                                                                        |
| <i>connectionmissratio</i>  | Specifies the percentage of LDAP operations that can miss an LDAP handle in the first attempt (handle-miss). If the number of missed attempts reaches this value, the <b>secldapclntd</b> daemon adds a new connection. The total number of connections do not exceed the value of the <i>connectionsperserver</i> field. The valid value of this field ranges from 10 through 90. The default value is 50.                                                                                                                                                                                                                                                                                                                                   |
| <i>newconnT</i>             | Specifies the interval to check for connection-miss-ratio ( <i>connectionmissratio</i> ) to determine if a new connection needs to be created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>connectiontimeout</i>    | Specifies time in seconds that an LDAP connection to the server can be idle before the <b>secldapclntd</b> daemon closes it. The valid value is 5 seconds or greater. The default value is 300.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>serverschematype</i>     | Specifies the schema type of the LDAP server. It is set by the <b>mksecldap</b> command at LDAP client configuration time. Do not modify this attribute. Valid values are: rfc2307aix, rfc2307, aix, sfu30, and sfur2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>enableutf8_xlation</i>   | Enables the saving of data to the LDAP server in UTF-8 format. Valid values are <b>yes</b> and <b>no</b> . The default value is <b>no</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>rbacinterval</i>         | Specifies the time interval (in seconds) for the <b>secldapclntd</b> daemon to invoke the <b>setkst</b> command to update the kernel RBAC tables. The value must be greater than 60 seconds. Set the value to 0 to disable the <b>setkst</b> command. The default value is <b>3600</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>useprivport</i>          | Specifies whether to use local privileged ports to connect to LDAP servers. The valid values are <b>yes</b> and <b>no</b> . The default value is <b>no</b> . The <i>useprivport</i> attribute is for backward compatibility only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>memberfulldn</i>         | Specifies whether to use DN or account name for group members. The valid values are <b>yes</b> and <b>no</b> . The default value is <b>no</b> . In most cases when you use account names, do not change the value of the <i>memberfulldn</i> attribute. If you want group members in DN format, set the value to <b>yes</b> . For backward compatibility, if the LDAP server is Active Directory, the group member attribute is mapped to the <b>msSFU30PosixMember</b> member. The <b>secldapclntd</b> daemon always uses DN format regardless of this setting.                                                                                                                                                                              |
| <i>pwdpolicydn</i>          | Specifies the DN of the LDAP server global password policies. The <b>secldapclntd</b> daemon uses this policy entry to inform the user what is wrong in case of a noncompliant password. If you have specified password policies, these policies are used instead of the global policies.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>usrkeystorebasedn</i>    | Specifies the User's EFS PKCS#12 keystore base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>grpkeystorebasedn</i>    | Specifies the Groups's EFS PKCS#12 keystore base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>efscookiesbasedn</i>     | Specifies the EFS Cookie base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>admkeystorebasedn</i>    | Specifies the EFS Admin's PKCS#12 keystore base DN. For more information, see Detailed information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>followreferrals</i>      | Specifies if the AIX LDAP client should chase the referrals received from the LDAP server. The valid values are <b>on</b> and <b>off</b> , default is <b>on</b> meaning chase the referrals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>caseExactAccountName</i> | Specifies whether to match account names as case-sensitive or case-insensitive. Most LDAP servers treat account names as case-insensitive. Therefore, account names like foo, Foo, FOo, and FOO are treated as the same user, and these servers allow only one of them defined in LDAP. The valid values are:<br><br><b>No</b> Specifies to return account name which matches the requested name as case-insensitive. For example, querying user foo may return any of foo, Foo, FOo, and FOO. This is the default value.<br><br><b>Yes</b> Specifies to return account name which matches the requested name as case-sensitive. For example, querying user foo will fail if one of the names Foo, FOo, or FOO exists in LDAP instead of foo. |

| Item                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>auditpolicy</i>    | <p>Specifies the action that needs to be taken if there is any change in audit configuration on LDAP. It is effective only when an attribute <i>auditrefreshed</i> is set. It takes following two values:</p> <p><b>WARN</b> Logs in message in the syslog file on LDAP client, whenever there is a change in audit configuration on LDAP so that administrator starts auditing on the LDAP client.</p> <p><b>RESTART</b> Automatically starts the auditing on the LDAP client, whenever there is a change in audit configuration on LDAP.</p> |
| <i>auditrefreshed</i> | <p>Specifies the time interval (in seconds) or time in 24 hour format for the <b>secldapclntd</b> daemon to take action according to the <i>auditpolicy</i> attribute. If the <i>auditpolicy</i> attribute is not set then this attribute is disabled. The time interval mentioned in seconds. The value must be greater than 60 seconds. Set the value to 0 to disable it. The default value is 3600. If the time is mentioned in 24 hr format then it should start with letter T.</p>                                                        |

## Detailed information

- Multiple base DNs

All of the base DN attributes accept multiple values, with each *<basedn>: <value>* pair on a separate line. For example, to allow users in the *ou=dept1users,cn=aixdata* base DNs and the *ou=dept2users,cn=aixdata* base DNs to log in to the system, you can specify the **userbasedn** attribute as follows:

```
userbasedn: ou=dept1users,cn=aixdata
userbasedn: ou=dept2users,cn=aixdata
```

You can specify up to 10 base DNs for each entity in the */etc/security/ldap/ldap.cfg* file. The base DNs are prioritized in the order they appear in the */etc/security/ldap/ldap.cfg* file. The following list describes the system behaviors in regards to multiple base DNs:

- Query operations, such as the **lsuser** command, are done according to the base DN order that is specified until a matching account is found. A failure is returned only if all of the base DNs are searched without finding a match.
- Modification operations, such as the **chuser** command, are done to the first matching account.
- Deletion operations, such as the **rmuser** command, are done to the first matching account.
- Creation operations, such as the **mkuser** command, are done only to the first base DN.

- Domain RBAC base DNs

```
#domainbasedn:ou=domains,cn=aixdata
#domobjbasedn:ou=domobjs,cn=aixdata
```

The time interval in minutes specifies the frequency in which the kernel RBAC and the domain RBAC tables are updated. A value of 0 disables the automatic update.

```
rbacinterval: 0
```

- Extended base DN format

You can specify optional parameters of search scope and search filter for base DN attributes. You can append the parameters to the base DN with fields separated by question mark (?) characters. The following list shows the valid base DN formats:

- This format represents the default format that the **secldapclntd** daemon uses:  
`userbasedn: ou=people, cn=aixdata`
- This format limits the search by a scope attribute:  
`userbasedn: ou=people, cn=aixdata?scope`

The scope attribute accepts the following values:

- **sub**
- **one**
- **base**

If you do not specify the scope attribute, the default value is **sub**.

- This format limits the search by a filter attribute.

```
userbasedn: ou=people, cn=aixdata??filter
```

The filter attribute limits the entries that are defined in the LDAP server. You can use this filter to make only users with certain properties visible to the system. The following list shows some valid filter formats, where *attribute* is the name of an LDAP attribute, and *value* specifies the search criteria, which can be a wild card (\*).

- (*attribute*=*value*)
- (&(*attribute*=*value*) (*attribute*=*value*))
- ((|(*attribute*=*value*) (*attribute*=*value*))
- This format uses both a scope attribute and a filter attribute.

```
userbasedn: ou=people, cn=aixdata?scope?filter
```

- Object classes

The first object class in the list is the key object class, which can be used for search operations. By default, the **keyobjectclass** attribute in the attribute mapping file is used for this purpose. But if the mapping file does not exist, or the **keyobjectclass** attribute is not present in the mapping file, the first object class in this list is used.

## LDAP Attribute Mapping File Format

### Purpose

Defines AIX to LDAP attribute name mapping to support configurable LDAP server schema.

### Description

These map files are used by the **/usr/lib/security/LDAP** module and the **secldapclntd** daemon for translation between AIX attribute names to LDAP attribute names. Each entry in a mapping file represents a translation for an attribute. A entry has five space separated fields:

```
AIX_Attribute_Name AIX_Attribute_Type LDAP_Attribute_Name LDAP_Value_Type LDAP_Value_Unit
```

| Item                       | Description                                                                                       |
|----------------------------|---------------------------------------------------------------------------------------------------|
| <b>AIX_Attribute_Name</b>  | Specifies the AIX attribute name.                                                                 |
| <b>AIX_Attribute_Type</b>  | Specifies the AIX attribute type. Values are SEC_CHAR, SEC_INT, SEC_LIST, and SEC_BOOL.           |
| <b>LDAP_Attribute_Name</b> | Specifies the LDAP attribute name.                                                                |
| <b>LDAP_Value_Type</b>     | Specifies the LDAP value type. Values are <b>s</b> for single value and <b>m</b> for multi-value. |

| Item                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LDAP_Value_Unit</b> | <p>Specifies the LDAP value unit for some attributes. The following values are available for the <b>maxage</b>, <b>minage</b>, <b>maxexpires</b>, and the <b>pwdwarntime</b> attributes:</p> <ul style="list-style-type: none"> <li>• seconds</li> <li>• minutes</li> <li>• hours</li> <li>• days</li> <li>• weeks</li> <li>• months</li> <li>• years</li> </ul> <p>The following values are available for the <b>cpu</b>, <b>cpu_hard</b>, <b>fsize</b>, <b>fsize_hard</b>, <b>rss</b>, <b>rss_hard</b>, <b>stack</b>, and the <b>stack_hard</b> attributes:</p> <ul style="list-style-type: none"> <li>• bytes</li> <li>• 512-byte blocks</li> <li>• kilobytes</li> <li>• megabytes</li> <li>• gigabytes</li> </ul> <p>For all of the other attributes, the value is N/A. If no unit mapping is required, the values are also N/A.</p> |
| <b>TO_BE_CACHED</b>    | Specifies whether this attribute is to be cached. Valid values are <b>yes</b> and <b>no</b> . Default is <b>yes</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Files

AIX includes the following sets of attribute mapping files in the **/etc/security/ldap** directory:

The following attribute mappings are defined for AIX specific schema:

| Item                | Description                                                |
|---------------------|------------------------------------------------------------|
| <b>aixuser.map</b>  | Specifies the mapping for the aixAccount object class.     |
| <b>aixgroup.map</b> | Specifies the mapping for the aixAccessGroup object class. |
| <b>aixid.map</b>    | Specifies the mapping for the aixAdmin object class.       |

The following attribute mappings are defined for nisSchema (RFC 2307):

| Item                 | Description                                              |
|----------------------|----------------------------------------------------------|
| <b>2307user.map</b>  | Specifies the mapping for the posixAccount object class. |
| <b>2307group.map</b> | Specifies the mapping for the posixGroup object class.   |

The following attribute mappings are defined for nisSchema with AIX extensions:

| Item                    | Description                                                                                 |
|-------------------------|---------------------------------------------------------------------------------------------|
| <b>2307aixuser.map</b>  | Specifies the mapping for the posixAccount object class and the aixAuxAccount object class. |
| <b>2307aixgroup.map</b> | Specifies the mapping for the posixGroup object class and the aixAuxGroup object class.     |

The following attribute mappings are defined for Active Directory with service for UNIX:

| Item                  | Description                                       |
|-----------------------|---------------------------------------------------|
| <b>sfu30user.map</b>  | Specifies the mapping for the user object class.  |
| <b>sfu30group.map</b> | Specifies the mapping for the group object class. |

The following attribute mappings are defined for Active Directory with Windows 2003 R2 schema:

| Item                  | Description                                       |
|-----------------------|---------------------------------------------------|
| <b>sfur2user.map</b>  | Specifies the mapping for the user object class.  |
| <b>sfur2group.map</b> | Specifies the mapping for the group object class. |

The **mksecldap** command, at LDAP client configuration, will automatically figure out the server type and select the corresponding mapping files to use. If an LDAP server uses schema that is not included in these mapping files under the **/etc/security/ldap** directory, you must configure the LDAP client manually by creating your own mapping sets and edit the **/etc/security/ldap.cfg** file to use your mapping files.

The user and group maps might contain an entry that is used to designate the required object class that each user or group must have. This object class will be used in the filter for searches performed on user or group entries. As an example, listed below are the default entries for the **keyobjectclass** in the **aix2307user.map** and **aix2307group.map** files.

```
aix2307user.map:
 keyobjectclass SEC_CHAR posixgroup s na yes
aix2307group.map:
 keyobjectclass SEC_CHAR posixaccount s na yes
```

The **aixid.map** contains attribute mappings for user and group IDs. The IDs are used when one creates a new LDAP user/group with the **mkuser** or **mkgroup** command.

## Locale Definition Source File Format

### Purpose

Contains one or more categories that describe a locale.

### Description

A locale definition source file contains one or more categories that describe a locale. Files using this format can be converted into a locale by using the **localedef** command. Locales can be modified only by editing a locale definition source file and then using the **localedef** command again on the new source file. Locales are not affected by a locale definition source file unless the file is first converted using the **localedef** command.

The locale definition source file sections define categories of locale data. A source file should not contain more than one section for the same category. The following categories are supported:

| Item                     | Description                                                                          |
|--------------------------|--------------------------------------------------------------------------------------|
| <code>LC_COLLATE</code>  | Defines character or string collation information.                                   |
| <code>LC_CTYPE</code>    | Defines character classification, case conversion, and other character attributes.   |
| <code>LC_MESSAGES</code> | Defines the format for affirmative and negative responses.                           |
| <code>LC_MONETARY</code> | Defines rules and symbols for formatting monetary numeric information.               |
| <code>LC_NUMERIC</code>  | Defines a list of rules and symbols for formatting non-monetary numeric information. |
| <code>LC_TIME</code>     | Defines a list of rules and symbols for formatting time and date information.        |

The category definition consists of:

- The category header (category name)
- The associated keyword/value pairs that comprise the category body
- The category trailer (which consists of `END category-name`)

For example:

**`LC_CTYPE source for LC_CTYPE category END LC_CTYPE`**

The source for all of the categories is specified using keywords, strings, character literals, and character symbols. Each keyword identifies either a definition or a rule. The remainder of the statement containing the keyword contains the operands to the keyword. Operands are separated from the keyword by one or more blank characters. A statement may be continued on the next line by placing a / (slash) as the last character before the new-line character that terminates the line. Lines containing the `comment_char` entry in the first column are treated as comment lines. The default is # (pound sign).

The first category header in the file can be preceded by a line that changes the comment character. It has the following format, starting in column 1:

`comment_char character`

where `character` is the new comment character.

Blank lines and lines containing the comment character in the first position are ignored.

A character symbol begins with the < (less-than) character, followed by up to 30 non-control, non-space characters, and ends with the > (greater-than) character. For example, <A-diaeresis> is a valid character symbol. Any character symbol referenced in the source file should either be one of the portable character set symbols or should be defined in the provided character set description (`charmap`) source file.

A character literal is the character itself, or else a decimal, hexadecimal, or octal constant. A decimal constant is of the form:

`\dxx`

where `x` is a decimal digit. A hexadecimal constant is of the form:

`\xddd`

where `d` is a hexadecimal digit. An octal constant is of the form:

`\ddd`

where `d` is an octal digit.

A string is a sequence of character symbols, or literals enclosed by " " (double-quotation marks). For example:

`"<A-diaeresis> \d65\d120 <B>"`

The explicit definition of each category in a locale definition source file is not required. When a category is undefined in a locale definition source file, it defaults to the C locale definition.

The first category header in the file can be preceded by a line that changes the escape character used in the file. It has the following format, starting in column 1:

*escape\_char character*

where *character* is the new escape character.

The escape character defaults to the / (backslash).

## LC\_COLLATE Category for the Locale Definition Source File Format

### Purpose

Defines character or string collation information.

### Description

A collation element is the unit of comparison for collation. A collation element may be a character or a sequence of characters. Every collation element in the locale has a set of weights, which determine if the collation element collates before, equal to, or after the other collation elements in the locale. Each collation element is assigned collation weights by the **localeddef** command when the locale definition source file is converted. These collation weights are then used by applications programs that compare strings.

Comparison of strings is performed by comparing the collation weights of each character in the string until either a difference is found or the strings are determined to be equal. This comparison may be performed several times if the locale defines multiple collation orders. For example, in the French locale, the strings are compared using a primary set of collation weights. If they are equal on the basis of this comparison, they are compared again using a secondary set of collation weights. A collating element has a set of collation weights associated with it that is equal to the number of collation orders defined for the locale.

Every character defined in the **charmap** file (or every character in the portable character set if no **charmap** file is specified) is itself a collating element. Additional collating elements can be defined using the **collating-element** statement. The syntax is:

**collating-element** *character-symbol from string*

The LC\_COLLATE category begins with the LC\_COLLATE keyword and ends with the END LC\_COLLATE keyword.

The following keywords are recognized in the **LC\_COLLATE** category:

| Item                     | Description                                                                                                                                                                                              |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>copy</b>              | The <b>copy</b> statement specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified. |
| <b>collating-element</b> | The <b>collating-element</b> statement specifies multicharacter collating elements.                                                                                                                      |

The syntax for the **collating-element** statement is:

**collating-element <collating-symbol> from <string>**

The *collating-symbol* value defines a collating element that is a string of one or more characters as a single collating element. The *collating-symbol* value cannot duplicate any symbolic name in the current **charmap** file, or any other symbolic name defined in this collation definition. The *string* value specifies a string of two or more characters that define the *collating-symbol* value. Following are examples of the syntax for the **collating-element** statement:

**collating-element <ch> from <c><h> collating-element <e-acute> from <acute><e> collating-element <11> from <1><1>**

A *collating-symbol* value defined by the **collating-element** statement is recognized only with the **LC\_COLLATE** category.

| Item                    | Description                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------|
| <b>collating-symbol</b> | The <b>collating-symbol</b> statement specifies collation symbols for use in collation sequence statements. |

The syntax for the **collating-symbol** statement is:

**collating-symbol <collating-symbol>**

The *collating-symbol* value cannot duplicate any symbolic name in the current **charmap** file, or any other symbolic name defined in this collation definition. Following are examples of the syntax for the **collating-symbol** statement:

**collating-symbol <UPPER\_CASE> collating-symbol <HIGH>**

A *collating-symbol* value defined by the **collating-symbol** statement is recognized only within the **LC\_COLLATE** category.

| Item               | Description                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>order_start</b> | The <b>order_start</b> statement must be followed by one or more collation order statements, assigning collation weights to collating elements. This statement is mandatory. |

The syntax for the **order\_start** statement is:

**order\_start <sort-rules>, <sort-rules>,...<sort-rules> collation order statements order\_end**

The *<sort-rules>* directives have the following syntax:

*keyword, keyword,...keyword; keyword, keyword,...keyword*

where *keyword* is one of the keywords **forward**, **backward**, and **position**.

The *sort-rules* directives are optional. If present, they define the rules to apply during string comparison. The number of specified *sort-rules* directives defines the number of weights each collating element is assigned (that is, the number of collation orders in the locale). If no *sort-rules* directives are present, one **forward** keyword is assumed and comparisons are made on a character basis rather than a string basis. If present, the first *sort-rules* directive applies when comparing strings using primary weight, the second when comparing strings using the secondary weight, and so on. Each set of *sort-rules* directives is separated by a ; (semicolon). A *sort-rules* directive consists of one or more comma-separated keywords. The following keywords are supported:

| Item            | Description                                                                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>forward</b>  | Specifies that collation weight comparisons proceed from the beginning of a string toward the end of the string.                                                                                                                                                                       |
| <b>backward</b> | Specifies that collation weight comparisons proceed from the end of a string toward the beginning of the string.                                                                                                                                                                       |
| <b>position</b> | Specifies that collation weight comparisons consider the relative position of elements in the string not subject to the special symbol <b>IGNORE</b> . That is, if strings compare equal, the element with the shortest distance from the starting point of the string collates first. |

The **forward** and **backward** keywords are mutually exclusive. Following is an example of the syntax for the <*sort-rules*> directives:

**order\_start** *forward; backward, position*

The optional operands for each collation element are used to define the primary, secondary, or subsequent weights for the collating element. The special symbol **IGNORE** is used to indicate a collating element that is to be ignored when strings are compared.

A collation statement with the **ellipsis** keyword on the left-hand side results in the *collating-element-list* on the right-hand side being applied to every character with an encoding that falls numerically between the character on the left-hand side in the preceding statement and the character on the left-hand side of the following statement. If the **ellipsis** occur in the first statement, it is interpreted as though the preceding line specified the **NUL** character. (The **NUL** character is a character with all bits set to 0.) If the **ellipsis** occur in the last statement, it is interpreted as though the following line specified the greatest encoded value.

An **ellipsis** keyword appearing in place of a *collating-element-list* indicates the weights are to be assigned, for the characters in the identified range, in numerically increasing order from the weight for the character symbol on the left-hand side of the preceding statement.

**Note:** The use of the **ellipsis** keyword results in a locale that may collate differently when compiled with different character set description (**charmap**) source files. For this reason, the **localedef** command issues a warning when the **ellipsis** keyword is encountered.

All characters in the character set must be placed in the collation order, either explicitly or implicitly by using the **UNDEFINED** special symbol. The **UNDEFINED** special symbol includes all coded character set values not specified explicitly or with an ellipsis symbol. These characters are inserted in the character collation order at the point indicated by the **UNDEFINED** special symbol in the order of their character code set values. If no **UNDEFINED** special symbol exists and the collation order does not specify all collation elements from the coded character set, a warning is issued and all undefined characters are placed at the end of the character collation order.

## Examples

The following is an example of a collation order statement in the **LC\_COLLATE** locale definition source file category:

```
order_start forward;backward
UNDEFINED IGNORE;IGNORE
<LOW> <LOW>;<space>
```

```

...
<LOW>;...
<a> <a>;<a>
<a-acute> <a>;<a-acute>
<a-grave> <a>;<a-grave>
<A> <a>;<A>
<A-acute> <a>;<A-acute>
<A-grave> <a>;<A-grave>
<ch> <ch>;<ch>
<Ch> <ch>;<Ch>
<s> <s>;<s>
<ss> <s><s>;<s><s>
<eszet> <s><s>;<eszet><eszet>
...
<HIGH>
order_end

```

This example is interpreted as follows:

- The **UNDEFINED** special symbol indicates that all characters not specified in the definition (either explicitly or by the ellipsis symbol) are ignored for collation purposes.
- All collating elements between `<space>` and `<a>` have the same primary equivalence class and individual secondary weights based on their coded character set values.
- All characters based on the uppercase or lowercase `a` character belong to the same primary equivalence class.
- The `<c><h>` multicharacter collating element is represented by the `<ch>` collating symbol and belongs to the same primary equivalence class as the `<C><h>` multicharacter collating element.
- The `<eszet>` character is collated as an `<s><s>` string. That is, one `<eszet>` character is expanded to two characters before comparing.

## LC\_CTYPE Category for the Locale Definition Source File Format

### Purpose

Defines character classification, case conversion, and other character attributes.

### Description

The **LC\_CTYPE** category of a locale definition source file defines character classification, case conversion, and other character attributes. This category begins with an **LC\_CTYPE** category header and terminates with an **END LC\_CTYPE** category trailer.

All operands for **LC\_CTYPE** category statements are defined as lists of characters. Each list consists of one or more semicolon-separated characters or symbolic character names.

The following keywords are recognized in the **LC\_CTYPE** category. In the descriptions, the term *automatically included* means that an error does not occur if the referenced characters are included or omitted. The characters will be provided if they are missing and will be accepted if they are present.

| Item                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>copy</b>           | Specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified.                                                                                                                                                                                                                                                                                                              |
| <b>upper</b>          | Defines uppercase letter characters. No character defined by the <b>cntrl</b> , <b>digit</b> , <b>punct</b> , or <b>space</b> keyword can be specified. At a minimum, the uppercase letters A-Z must be defined.                                                                                                                                                                                                                                                                            |
| <b>lower</b>          | Defines lowercase letter characters. No character defined by the <b>cntrl</b> , <b>digit</b> , <b>punct</b> , or <b>space</b> keyword can be specified. At a minimum, the lowercase letters a-z must be defined.                                                                                                                                                                                                                                                                            |
| <b>alpha</b>          | Defines all letter characters. No character defined by the <b>cntrl</b> , <b>digit</b> , <b>punct</b> , or <b>space</b> keyword can be specified. Characters defined by the <b>upper</b> and <b>lower</b> keywords are automatically included in this character class.                                                                                                                                                                                                                      |
| <b>digit</b>          | Defines numeric digit characters. Only the digits 0, 1, 2, 3, 4, 5, 6, 7, 8, and 9 can be specified.                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>alnum</b>          | Defines alphanumeric characters. No character defined by the <b>cntrl</b> , <b>punct</b> , or <b>space</b> keyword can be specified. Characters defined by the <b>alpha</b> and <b>digit</b> keywords are automatically included in this character class.                                                                                                                                                                                                                                   |
| <b>space</b>          | Defines whitespace characters. No character defined by the <b>upper</b> , <b>lower</b> , <b>alpha</b> , <b>digit</b> , <b>graph</b> , <b>cntrl</b> , or <b>xdigit</b> keyword can be specified. At a minimum, the <space>, <form-feed>, <newline>, <carriage return>, <tab>, and <vertical-tab> characters, and any characters defined by the <b>blank</b> keyword, must be specified.                                                                                                      |
| <b>cntrl</b>          | Defines control characters. No character defined by the <b>upper</b> , <b>lower</b> , <b>alpha</b> , <b>digit</b> , <b>punct</b> , <b>graph</b> , <b>print</b> , <b>xdigit</b> , or <b>space</b> keyword can be specified.                                                                                                                                                                                                                                                                  |
| <b>punct</b>          | Defines punctuation characters. A character defined as the <space> character and characters defined by the <b>upper</b> , <b>lower</b> , <b>alpha</b> , <b>digit</b> , <b>cntrl</b> , or <b>xdigit</b> keyword cannot be specified.                                                                                                                                                                                                                                                         |
| <b>graph</b>          | Defines printable characters, excluding the <space> character. If this keyword is not specified, characters defined by the <b>upper</b> , <b>lower</b> , <b>alpha</b> , <b>digit</b> , <b>xdigit</b> , and <b>punct</b> keywords are automatically included in this character class. No character defined by the <b>cntrl</b> keyword can be specified.                                                                                                                                     |
| <b>print</b>          | Defines printable characters, including the <space> character. If this keyword is not specified, the <space> character and characters defined by the <b>upper</b> , <b>lower</b> , <b>alpha</b> , <b>digit</b> , <b>xdigit</b> , and <b>punct</b> keywords are automatically included in this character class. No character defined by the <b>cntrl</b> keyword can be specified.                                                                                                           |
| <b>xdigit</b>         | Defines hexadecimal digit characters. The digits 0-9 and the letters A-F and a-f can be specified. The <b>xdigit</b> keyword defaults to its normal class limits.                                                                                                                                                                                                                                                                                                                           |
| <b>blank</b>          | Defines blank characters. If this keyword is not specified, the <space> and <horizontal-tab> characters are included in this character class. Any characters defined by this statement are automatically included in the <b>space</b> keyword class.                                                                                                                                                                                                                                        |
| <b>charclass</b>      | Defines one or more locale-specific character class names as strings separated by semicolons. Each named character class can then be defined subsequently in the <b>LC_CTYPE</b> definition. A character class name consists of at least one, and at most 32 bytes, of alphanumeric characters from the portable character set symbols. The first character of a character class name cannot be a digit. The name cannot match any of the <b>LC_CTYPE</b> keywords defined in this section. |
| <i>charclass-name</i> | Defines characters to be classified as belonging to the named locale-specific character class. Locale-specific named character classes need not exist in the POSIX locale.                                                                                                                                                                                                                                                                                                                  |
|                       | If a class name is defined by a <b>charclass</b> keyword, but no characters are subsequently assigned to it, it represents a class without any characters belonging to it.                                                                                                                                                                                                                                                                                                                  |
|                       | The <i>charclass-name</i> can be used as the <i>Property</i> parameter in the <b>wctype</b> subroutine, in regular expressions and shell pattern-matching expressions, and by the <b>tr</b> command.                                                                                                                                                                                                                                                                                        |
| <b>toupper</b>        | Defines the mapping of lowercase characters to uppercase characters. Operands for this keyword consist of semicolon-separated character pairs. Each character pair is enclosed in () (parentheses) and separated from the next pair by a , (comma). The first character in each pair is considered lowercase; the second character is considered uppercase. Only characters defined by the <b>lower</b> and <b>upper</b> keywords can be specified.                                         |
| <b>tolower</b>        | Defines the mapping of uppercase characters to lowercase characters. Operands for this keyword consist of semicolon-separated character pairs. Each character pair is enclosed in () (parentheses) and separated from the next pair by a , (comma). The first character in each pair is considered uppercase; the second character is considered lowercase. Only characters defined by the <b>lower</b> and <b>upper</b> keywords can be specified.                                         |

The **tolower** keyword is optional. If this keyword is not specified, the mapping defaults to the reverse mapping of the **toupper** keyword, if specified. If the **toupper** and **tolower** keywords are both unspecified, the mapping for each defaults to that of the C locale.

The **LC\_CTYPE** category does not support multicharacter elements. For example, the German sharp-s character is traditionally classified as a lowercase letter. There is no corresponding uppercase letter; in proper capitalization of German text, the sharp-s character is replaced by the two characters ss. This kind of conversion is outside of the scope of the **toupper** and **tolower** keywords.

## Examples

The following is an example of a possible **LC\_CTYPE** category listed in a locale definition source file:

```
LC_CTYPE
#"alpha" is by default "upper" and "lower"
#"alnum" is by default "alpha" and "digit"
#"print" is by default "alnum", "punct" and the space character
#"graph" is by default "alnum" and "punct"
#"tolower" is by default the reverse mapping of "toupper"
#
upper <A>;;<C>;<D>;<E>;<F>;<G>;<H>;<I>;<J>;<K>;<L>;<M>;\
<N>;<O>;<P>;<Q>;<R>;<S>;<T>;<U>;<V>;<W>;<X>;<Y>;<Z>
#
lower <a>;;<c>;<d>;<e>;<f>;<g>;<h>;<i>;<j>;<k>;<l>;<m>;\
<n>;<o>;<p>;<q>;<r>;<s>;<t>;<u>;<v>;<w>;<x>;<y>;<z>
#
digit <zero>;<one>;<two>;<three>;<four>;<five>;<six>;\
<seven>;<eight>;<nine>
#
space <tab>;<newline>;<vertical-tab>;<form-feed>;\
<carriage-return>;<space>
#
cntrl <alert>;<backspace>;<tab>;<newline>;<vertical-tab>;/
<form-feed>;<carriage-return>;<NUL>;<SOH>;<STX>;/
<ETX>;<EOT>;<ENO>;<ACK>;<S0>;<SI>;<DLE>;<DC1>;<DC2>;/
<DC3>;<DC4>;<NAK>;<SYN>;<ETB>;<CAN>;;<SUB>;/
<ESC>;<IS4>;<IS3>;<IS2>;<IS1>;
#
punct <exclamation-mark>;<quotation-mark>;<number-sign>;\
<dollar-sign>;<percent-sign>;<ampersand>;<asterisk>;\
<apostrophe>;<left-parenthesis>;<right-parenthesis>;
<plus-sign>;<comma>;<hyphen>;<period>;<slash>;/
<colon>;<semicolon>;<less-than-sign>;<equals-sign>;\
<greater-than-sign>;<question-mark>;<commercial-at>;\
<left-square-bracket>;<backslash>;<circumflex>;\
<right-square-bracket>;<underline>;<grave-accent>;\
<left-curly-bracket>;<vertical-line>;<tilde>;\
<right-curly-bracket>
#
xdigit <zero>;<one>;<two>;<three>;<four>;<five>;<six>;\
<seven>;<eight>;<nine>;<A>;;<C>;<D>;<E>;<F>;\
<a>;;<c>;<d>;<e>;<f>
#
blank <space>;<tab>
#
toupper (<a>,<A>);(,);(<c>,<C>);(<d>,<D>);(<e>,<E>);\
(<f>,<F>);(<g>,<G>);(<h>,<H>);(<i>,<I>);(<j>,<J>);\
(<k>,<K>);(<l>,<L>);(<m>,<M>);(<n>,<N>);(<o>,<O>);\
(<p>,<P>);(<q>,<Q>);(<r>,<R>);(<s>,<S>);(<t>,<T>);\
(<u>,<U>);(<v>,<V>);(<w>,<W>);(<x>,<X>);(<y>,<Y>);\
(<z>,<Z>)
#
END LC_CTYPE
```

## Files

| Item                   | Description                                                                                |
|------------------------|--------------------------------------------------------------------------------------------|
| /usr/lib/nls/loc/*     | Specifies locale definition source files for supported locales.                            |
| /usr/lib/nls/charmap/* | Specifies character set description ( <b>charmap</b> ) source files for supported locales. |

## LC\_MESSAGES Category for the Locale Definition Source File Format

### Purpose

Defines the format for affirmative and negative system responses.

### Description

The **LC\_MESSAGES** category of a locale definition source file defines the format for affirmative and negative system responses. This category begins with an **LC\_MESSAGES** category header and terminates with an **END LC\_MESSAGES** category trailer.

All operands for the **LC\_MESSAGES** category are defined as strings or extended regular expressions enclosed by " " (double-quotation marks). These operands are separated from the keyword they define by one or more blanks. Two adjacent " " (double-quotation marks) indicate an undefined value. The following keywords are recognized in the **LC\_MESSAGES** category:

| Item    | Description                                                                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| copy    | Specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified.     |
| yesexpr | Specifies an extended regular expression that describes the acceptable affirmative response to a question expecting an affirmative or negative response.                           |
| noexpr  | Specifies an extended regular expression that describes the acceptable negative response to a question expecting an affirmative or negative response.                              |
| yesstr  | A colon-separated string of acceptable affirmative responses. This string is accessible to applications through the <b>nl_langinfo</b> subroutine as <b>nl_langinfo (YESSTR)</b> . |
| nostr   | A colon-separated string of acceptable negative responses. This string is accessible to applications through the <b>nl_langinfo</b> subroutine as <b>nl_langinfo (NOSTR)</b> .     |

### Examples

The following is an example of a possible **LC\_MESSAGES** category listed in a locale definition source file:

```
LC_MESSAGES
#
yesexpr "([yY] [[:alpha:]]*)|(OK)"
noexpr "[nN] [[:alpha:]]*"
yesstr "Y:y:yes"
nostr "N:n:no"
#
END LC_MESSAGES
```

## LC\_MONETARY Category for the Locale Definition Source File Format

### Purpose

Defines rules and symbols for formatting monetary numeric information.

### Description

The **LC\_MONETARY** category of a locale definition source file defines rules and symbols for formatting monetary numeric information. This category begins with an **LC\_MONETARY** category header and terminates with an **END LC\_MONETARY** category trailer.

All operands for the **LC\_MONETARY** category keywords are defined as string or integer values. String values are enclosed by " " (double-quotation marks). All values are separated from the keyword they define by one or more spaces. Two adjacent double-quotation marks indicate an undefined string value. A -1 indicates an undefined integer value. The following keywords are recognized in the **LC\_MONETARY** category:

| Item                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>copy</b>              | Specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>int_curr_symbol</b>   | Specifies the string used for the international currency symbol. The operand for the <b>int_curr_symbol</b> keyword is a four-character string. The first three characters contain the alphabetic international-currency symbol. The fourth character specifies a character separator between the international currency symbol and a monetary quantity.                                                                                                                                                                                                                                                                                          |
| <b>currency_symbol</b>   | Specifies the string used for the local currency symbol.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>mon_decimal_point</b> | Specifies the string used for the decimal delimiter used to format monetary quantities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>mon_thousands_sep</b> | Specifies the character separator used for grouping digits to the left of the decimal delimiter in formatted monetary quantities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>mon_grouping</b>      | Specifies a string that defines the size of each group of digits in formatted monetary quantities. The operand for the <b>mon_grouping</b> keyword consists of a sequence of semicolon-separated integers. Each integer specifies the number of digits in a group. The initial integer defines the size of the group immediately to the left of the decimal delimiter. The following integers define succeeding groups to the left of the previous group. If the last integer is not -1, the size of the previous group (if any) is repeatedly used for the remainder of the digits. If the last integer is -1, no further grouping is performed. |

The following is an example of the interpretation of the **mon\_grouping** statement. Assuming the value to be formatted is 123456789 and the operand for the **mon\_thousands\_sep** keyword is ' (single-quotation mark), the following results occur:

|                           | <b>Formatted Value</b>                                                                                                                                                                                                              |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mon_grouping</b> Value |                                                                                                                                                                                                                                     |
| 3;-1                      | 123456'789                                                                                                                                                                                                                          |
| 3                         | 123'456'789                                                                                                                                                                                                                         |
| 3;2;-1                    | 1234'56'789                                                                                                                                                                                                                         |
| 3;2                       | 12'34'56'789                                                                                                                                                                                                                        |
|                           | <b>-1</b> 123456789                                                                                                                                                                                                                 |
| <b>positive_sign</b>      | Specifies the string used to indicate a nonnegative-valued formatted monetary quantity.                                                                                                                                             |
| <b>negative_sign</b>      | Specifies the string used to indicate a negative-valued formatted monetary quantity.                                                                                                                                                |
| <b>int_frac_digits</b>    | Specifies an integer value representing the number of fractional digits (those after the decimal delimiter) to be displayed in a formatted monetary quantity using the <b>int_curr_symbol</b> value.                                |
| <b>frac_digits</b>        | Specifies an integer value representing the number of fractional digits (those after the decimal delimiter) to be displayed in a formatted monetary quantity using the <b>currency_symbol</b> value.                                |
| <b>p_cs_precedes</b>      | Specifies an integer value indicating whether the <b>int_curr_symbol</b> or <b>currency_symbol</b> string precedes or follows the value for a nonnegative formatted monetary quantity. The following integer values are recognized: |
|                           | <b>0</b> Indicates that the currency symbol follows the monetary quantity.                                                                                                                                                          |
|                           | <b>1</b> Indicates that the currency symbol precedes the monetary quantity.                                                                                                                                                         |
| <b>p_sep_by_space</b>     | Specifies an integer value indicating whether the <b>int_curr_symbol</b> or <b>currency_symbol</b> string is separated by a space from a nonnegative formatted monetary quantity. The following integer values are recognized:      |
|                           | <b>0</b> Indicates that no space separates the currency symbol from the monetary quantity.                                                                                                                                          |
|                           | <b>1</b> Indicates that a space separates the currency symbol from the monetary quantity.                                                                                                                                           |
|                           | <b>2</b> Indicates that a space separates the currency symbol and the <b>positive_sign</b> string, if adjacent.                                                                                                                     |
| <b>n_cs_precedes</b>      | Specifies an integer value indicating whether the <b>int_curr_symbol</b> or <b>currency_symbol</b> string precedes or follows the value for a negative formatted monetary quantity. The following integer values are recognized:    |
|                           | <b>0</b> Indicates that the currency symbol follows the monetary quantity.                                                                                                                                                          |
|                           | <b>1</b> Indicates that the currency symbol precedes the monetary quantity.                                                                                                                                                         |
| <b>n_sep_by_space</b>     | Specifies an integer value indicating whether the <b>int_curr_symbol</b> or <b>currency_symbol</b> string is separated by a space from a negative formatted monetary quantity. The following integer values are recognized:         |
|                           | <b>0</b> Indicates that no space separates the currency symbol from the monetary quantity.                                                                                                                                          |
|                           | <b>1</b> Indicates that a space separates the currency symbol from the monetary quantity.                                                                                                                                           |
|                           | <b>2</b> Indicates that a space separates the currency symbol and the <b>negative_sign</b> string, if adjacent.                                                                                                                     |
| <b>p_sign_posn</b>        | Specifies an integer value indicating the positioning of the <b>positive_sign</b> string for a nonnegative formatted monetary quantity. The following integer values are recognized:                                                |
|                           | <b>0</b> Indicates that a <b>left_parenthesis</b> and <b>right_parenthesis</b> symbol enclose both the monetary quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                           |
|                           | <b>1</b> Indicates that the <b>positive_sign</b> string precedes the quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                                                      |
|                           | <b>2</b> Indicates that the <b>positive_sign</b> string follows the quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                                                       |
|                           | <b>3</b> Indicates that the <b>positive_sign</b> string immediately precedes the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                                                           |
|                           | <b>4</b> Indicates that the <b>positive_sign</b> string immediately follows the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                                                            |

| mon_grouping      | Value | Formatted Value                                                                                                                                                                      |
|-------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n_sign_posn       |       | Specifies an integer value indicating the positioning of the <b>negative_sign</b> string for a negative formatted monetary quantity. The following integer values are recognized:    |
| 0                 |       | Indicates that a <b>left_parenthesis</b> and <b>right_parenthesis</b> symbol enclose both the monetary quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.     |
| 1                 |       | Indicates that the <b>negative_sign</b> string precedes the quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                |
| 2                 |       | Indicates that the <b>negative_sign</b> string follows the quantity and the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                 |
| 3                 |       | Indicates that the <b>negative_sign</b> string immediately precedes the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                     |
| 4                 |       | Indicates that the <b>negative_sign</b> string immediately follows the <b>int_curr_symbol</b> or <b>currency_symbol</b> string.                                                      |
| debit_sign        |       | Specifies the string used for the debit symbol ( <b>DB</b> ) to indicate a nonnegative formatted monetary quantity.                                                                  |
| credit_sign       |       | Specifies the string used for the credit symbol ( <b>CR</b> ) to indicate a negative formatted monetary quantity.                                                                    |
| left_parenthesis  |       | Specifies the character, equivalent to a ( (left parenthesis), used by the <b>p_sign_posn</b> and <b>n_sign_posn</b> statements to enclose a monetary quantity and currency symbol.  |
| right_parenthesis |       | Specifies the character, equivalent to a ) (right parenthesis), used by the <b>p_sign_posn</b> and <b>n_sign_posn</b> statements to enclose a monetary quantity and currency symbol. |

A unique customized monetary format can be produced by changing the value of a single statement. For example, the following table shows the results of using all combinations of defined values for the **p\_cs\_precedes**, **p\_sep\_by\_space**, and **p\_sign\_posn** statements.

*Table 4. Results of Various Locale Variable Value Combinations*

| Item              | Description     |                                          |
|-------------------|-----------------|------------------------------------------|
| p_cs_precedes     | p_sign_posn     | p_sep_by_space =                         |
| p_cs_precedes = 1 | p_sign_posn = 0 | 2 (\$1.25)<br>1 (\$ 1.25)<br>0 (\$1.25)  |
|                   | p_sign_posn = 1 | 2 + \$1.25<br>1 +\$ 1.25<br>0 +\$1.25    |
|                   | p_sign_posn = 2 | 2 \$1.25 +<br>1 \$ 1.25+<br>0 \$1.25+    |
|                   | p_sign_posn = 3 | 2 + \$1.25<br>1 +\$ 1.25<br>0 +\$1.25    |
|                   | p_sign_posn = 4 | 2 \$ +1.25<br>1 \$+ 1.25<br>0 \$+1.25    |
| p_cs_precedes = 0 | p_sign_posn = 0 | 2 (1.25 \$)<br>1 (1.25 \$)<br>0 (1.25\$) |

Table 4. Results of Various Locale Variable Value Combinations (continued)

| Item | Description     |   |          |
|------|-----------------|---|----------|
|      | p_sign_posn = 1 | 2 | +1.25 \$ |
|      |                 | 1 | +1.25 \$ |
|      |                 | 0 | +1.25\$  |
|      | p_sign_posn = 2 | 2 | 1.25\$ + |
|      |                 | 1 | 1.25 \$+ |
|      |                 | 0 | 1.25\$+  |
|      | p_sign_posn = 3 | 2 | 1.25+ \$ |
|      |                 | 1 | 1.25 +\$ |
|      |                 | 0 | 1.25+\$  |
|      | p_sign_posn = 4 | 2 | 1.25\$ + |
|      |                 | 1 | 1.25 \$+ |
|      |                 | 0 | 1.25\$+  |

## Example

The following is an example of a possible **LC\_MONETARY** category listed in a locale definition source file:

```

LC_MONETARY
#
int_curr_symbol "<U><$><D>"
currency_symbol "<dollar-sign>"
mon_decimal_point "<period>"
mon_thousands_sep "<comma>"
mon_grouping "<3>"
positive_sign "<plus-sign>"
negative_sign "<hyphen>"
int_frac_digits "<2>"
frac_digits "<2>"
p_cs_precedes "<1>"
p_sep_by_space "<2>"
n_cs_precedes "<1>"
n_sep_by_space "<2>"
p_sign_posn "<3>"
n_sign_posn "<3>"
debit_sign "<D>"
credit_sign "<C><R>"
left_parenthesis "<left-parenthesis>"
right_parenthesis "<right-parenthesis>"
#
END LC_MONETARY

```

## Files

| Item                   | Description                                                                                |
|------------------------|--------------------------------------------------------------------------------------------|
| /usr/lib/nls/loc/*     | Specifies locale definition source files for supported locales.                            |
| /usr/lib/nls/charmap/* | Specifies character set description ( <b>charmap</b> ) source files for supported locales. |

## LC\_NUMERIC Category for the Locale Definition Source File Format

### Purpose

Defines rules and symbols for formatting non-monetary numeric information.

### Description

The **LC\_NUMERIC** category of a locale definition source file defines rules and symbols for formatting non-monetary numeric information. This category begins with an **LC\_NUMERIC** category header and terminates with an **END LC\_NUMERIC** category trailer.

All operands for the **LC\_NUMERIC** category keywords are defined as string or integer values. String values are enclosed by " " (double-quotation marks). All values are separated from the keyword they define by one or more spaces. Two adjacent double-quotation marks indicate an undefined string value. A -1 indicates an undefined integer value. The following keywords are recognized in the **LC\_NUMERIC** category:

| Item                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>copy</b>          | The <b>copy</b> statement specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified.                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>decimal_point</b> | Specifies the string used for the decimal delimiter used to format numeric, non-monetary quantities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>thousands_sep</b> | Specifies the string separator used for grouping digits to the left of the decimal delimiter in formatted numeric, non-monetary quantities.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>grouping</b>      | Defines the size of each group of digits in formatted monetary quantities. The operand for the <b>grouping</b> keyword consists of a sequence of semicolon-separated integers. Each integer specifies the number of digits in a group. The initial integer defines the size of the group immediately to the left of the decimal delimiter. The following integers define succeeding groups to the left of the previous group. If the last integer is not -1, the size of the previous group (if any) is used repeatedly for the remainder of the digits. If the last integer is -1, no further grouping is performed. |

The following is an example of the interpretation of the **grouping** statement. Assuming the value to be formatted is 123456789 and the operand for the **thousands\_sep** keyword is ' (single quotation mark) the following results occur:

| Grouping Value | Formatted Value |
|----------------|-----------------|
| 3;-1           | 123456'789      |
| 3              | 123'456'789     |
| 3;2;-1         | 123'45'6'789    |
| 3;2            | 12'34'56'789    |
| -1             | 123456789       |

### Examples

Following is an example of a possible **LC\_NUMERIC** category listed in a locale definition source file:

```
LC_NUMERIC
#
decimal_point "<period>"
```

```

thousands_sep "<comma>"

grouping <3>

END LC_NUMERIC

```

## LC\_TIME Category for the Locale Definition Source File Format

### Purpose

Defines rules and symbols for formatting time and date information.

### Description

The **LC\_TIME** category of a locale definition source file defines rules and symbols for formatting time and date information. This category begins with an **LC\_TIME** category header and terminates with an **END LC\_TIME** category trailer.

### Keywords

All operands for the **LC\_TIME** category keywords are defined as string or integer values. String values are enclosed by " " (double-quotation marks). All values are separated from the keyword they define by one or more spaces. Two adjacent double-quotation marks indicate an undefined string value. A -1 indicates an undefined integer value. Field descriptors are used by commands and subroutines that query the **LC\_TIME** category to represent elements of time and date formats. The following keywords are recognized in the **LC\_TIME** category:

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| copy    | The <b>copy</b> statement specifies the name of an existing locale to be used as the definition of this category. If a <b>copy</b> statement is included in the file, no other keyword can be specified.                                                                                                                                                                                               |
| abday   | Defines the abbreviated weekday names corresponding to the %a field descriptor. Recognized values consist of 7 semicolon-separated strings. Each string must be of equal length and contain 5 characters or less. The first string corresponds to the abbreviated name (Sun) for the first day of the week (Sunday), the second to the abbreviated name for the second day of the week, and so on.     |
| day     | Defines the full spelling of the weekday names corresponding to the %A field descriptor. Recognized values consist of seven semicolon-separated strings. The first string corresponds to the full spelling of the name of the first day of the week (Sunday), the second to the name of the second day of the week, and so on.                                                                         |
| abmon   | Defines the abbreviated month names corresponding to the %b field descriptor. Recognized values consist of 12 semicolon-separated strings. Each string must be of equal length and contain 5 characters or less. The first string corresponds to the abbreviated name (Jan) for the first month of the year (January), the second to the abbreviated name for the second month of the year, and so on. |
| mon     | Defines the full spelling of the month names corresponding to the %B field descriptor. Recognized values consist of 12 semicolon-separated strings. The first string corresponds to the full spelling of the name for the first month of the year (January), the second to the full spelling of the name for the second month of the year, and so on.                                                  |
| d_t_fmt | Defines the string used for the standard date and time format corresponding to the %c field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                    |

| Item               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>d_fmt</b>       | Defines the string used for the standard date format corresponding to the %x field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>t_fmt</b>       | Defines the string used for the standard time format corresponding to the %X field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>am_pm</b>       | Defines the strings used to represent <i>ante meridiem</i> (before noon) and <i>post meridiem</i> (after noon) corresponding to the %p field descriptor. Recognized values consist of two semicolon-separated strings. The first string corresponds to the <i>ante meridiem</i> designation, the last string to the <i>post meridiem</i> designation.                                                                                                                                                                                                                                  |
| <b>t_fmt_ampm</b>  | Defines the string used for the standard 12-hour time format that includes an <b>am_pm</b> value (the %p field descriptor). This statement corresponds to the %r field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                                                                                                                         |
| <b>era</b>         | Defines how the years are counted and displayed for each era (or emperor's reign) in a locale, corresponding to the %E field descriptor modifier. For each era, there must be one string in the following format:<br><i>direction:offset:start_date:end_date:name:format</i>                                                                                                                                                                                                                                                                                                           |
|                    | The variables for the era-string format are defined as follows:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>direction</i>   | Specifies a - (minus sign) or + (plus sign) character. The plus sign character indicates that years count in the positive direction when moving from the start date to the end date. The minus sign character indicates that years count in the negative direction when moving from the start date to the end date.                                                                                                                                                                                                                                                                    |
| <i>offset</i>      | Specifies a number representing the first year of the era.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>start_date</i>  | Specifies the starting date of the era in the <i>yyyy/mm/dd</i> format, where <i>yyyy</i> , <i>mm</i> , and <i>dd</i> are the year, month, and day, respectively. Years prior to the year AD 1 are represented as negative numbers. For example, an era beginning March 5th in the year 100 BC would be represented as -100/03/05.                                                                                                                                                                                                                                                     |
| <i>end_date</i>    | Specifies the ending date of the era in the same form used for the <i>start_date</i> variable or one of the two special values -* or +*. A -* value indicates that the ending date of the era extends backward to the beginning of time. A +* value indicates that the ending date of the era extends forward to the end of time. Therefore, the ending date can be chronologically before or after the starting date of the era. For example, the strings for the Christian eras AD and BC would be entered as follows:<br>+*:0:0000/01/01:+*:AD:%o %N<br>+:1:-0001/12/31:-*:BC:%o %N |
| <i>name</i>        | Specifies a string representing the name of the era that is substituted for the %N field descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>format</i>      | Specifies a string for formatting the %E field descriptor. This string is usually a function of the %o and %N field descriptors.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                    | An <b>era</b> value consists of one string for each era. If more than one era is specified, each era string is separated by a ; (semicolon).                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>era_year</b>    | Defines the string used to represent the year in alternate-era format corresponding to the %Ey field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>era_d_fmt</b>   | Defines the string used to represent the date in alternate-era format corresponding to the %Ex field descriptor. The string can contain any combination of characters and field descriptors.                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>era_t_fmt</b>   | Defines the alternative time format of the locale, as represented by the %Ex field descriptor for the <b>strftime</b> subroutine.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>era_d_t_fmt</b> | Defines the alternative date and time format of the locale, as represented by the %Ec field descriptor for the <b>strftime</b> subroutine.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>alt_digits</b>  | Defines alternate strings for digits corresponding to the %o field descriptor. Recognized values consist of a group of semicolon-separated strings. The first string represents the alternate string for 0, the second string represents the alternate string for one, and so on. A maximum of 100 alternate strings can be specified.                                                                                                                                                                                                                                                 |

## Field Descriptors

The **LC\_TIME** locale definition source file uses field descriptors to represent elements of time and date formats. Combinations of these field descriptors create other field descriptors or create time-and-date format strings. When used in format strings containing field descriptors and other characters, field

descriptors are replaced by their current values. All other characters are copied without change. The following field descriptors are used by commands and subroutines that query the **LC\_TIME** category for time formatting:

| Item | Description                                                                                                                                                                                                            |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %a   | Represents the abbreviated weekday name (for example, Sun) defined by the <b>abday</b> statement.                                                                                                                      |
| %A   | Represents the full weekday name (for example, Sunday) defined by the <b>day</b> statement.                                                                                                                            |
| %b   | Represents the abbreviated month name (for example, Jan) defined by the <b>abmon</b> statement.                                                                                                                        |
| %B   | Represents the full month name (for example, January) defined by the <b>month</b> statement.                                                                                                                           |
| %c   | Represents the time-and-date format defined by the <b>d_t_fmt</b> statement.                                                                                                                                           |
| %C   | Represents the century as a decimal number (00 to 99).                                                                                                                                                                 |
| %d   | Represents the day of the month as a decimal number (01 to 31).                                                                                                                                                        |
| %D   | Represents the date in %m/%d/%y format (for example, 01/31/91).                                                                                                                                                        |
| %e   | Represents the day of the month as a decimal number (01 to 31). The %e field descriptor uses a two-digit field. If the day of the month is not a two-digit number, the leading digit is filled with a space character. |
| %Ec  | Specifies the locale's alternate appropriate date and time representation.                                                                                                                                             |
| %EC  | Specifies the name of the base year (period) in the locale's alternate representation.                                                                                                                                 |
| %Ex  | Specifies the locale's alternate date representation.                                                                                                                                                                  |
| %EX  | Specifies the locale's alternate time representation.                                                                                                                                                                  |
| %Ey  | Specifies the offset from the %EC (year only) field descriptor in the locale's alternate representation.                                                                                                               |
| %EY  | Specifies the full alternate year representation.                                                                                                                                                                      |
| %Od  | Specifies the day of the month using the locale's alternate numeric symbols.                                                                                                                                           |
| %Oe  | Specifies the day of the month using the locale's alternate numeric symbols.                                                                                                                                           |
| %OH  | Specifies the hour (24-hour clock) using the locale's alternate numeric symbols.                                                                                                                                       |
| %OI  | Specifies the hour (12-hour clock) using the locale's alternate numeric symbols.                                                                                                                                       |
| %Om  | Specifies the month using the locale's alternate numeric symbols.                                                                                                                                                      |
| %OM  | Specifies the minutes using the locale's alternate numeric symbols.                                                                                                                                                    |
| %OS  | Specifies the seconds using the locale's alternate numeric symbols.                                                                                                                                                    |
| %OU  | Specifies the week number of the year (Sunday as the first day of the week) using the locale's alternate numeric symbols.                                                                                              |
| %Ow  | Specifies the weekday as a number in the locale's alternate representation (Sunday = 0).                                                                                                                               |

| Item | Description                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %OW  | Specifies the week number of the year (Monday as the first day of the week) using the locale's alternate numeric symbols.                                                                                                     |
| %Oy  | Specifies the year (offset from the %C field descriptor) in alternate representation.                                                                                                                                         |
| %h   | Represents the abbreviated month name (for example, Jan) defined by the <b>abmon</b> statement. This field descriptor is a synonym for the %b field descriptor.                                                               |
| %H   | Represents the 24-hour clock hour as a decimal number (00 to 23).                                                                                                                                                             |
| %I   | Represents the 12-hour clock hour as a decimal number (01 to 12).                                                                                                                                                             |
| %j   | Represents the day of the year as a decimal number (001 to 366).                                                                                                                                                              |
| %m   | Represents the month of the year as a decimal number (01 to 12).                                                                                                                                                              |
| %M   | Represents the minutes of the hour as a decimal number (00 to 59).                                                                                                                                                            |
| %n   | Specifies a new-line character.                                                                                                                                                                                               |
| %N   | Represents the alternate era name.                                                                                                                                                                                            |
| %o   | Represents the alternate era year.                                                                                                                                                                                            |
| %p   | Represents the a.m. or p.m. string defined by the <b>am_pm</b> statement.                                                                                                                                                     |
| %r   | Represents the 12-hour clock time with a.m./p.m. notation as defined by the <b>t_fmt_ampm</b> statement.                                                                                                                      |
| %S   | Represents the seconds of the minute as a decimal number (00 to 59).                                                                                                                                                          |
| %t   | Specifies a tab character.                                                                                                                                                                                                    |
| %T   | Represents 24-hour clock time in the format %H:%M:%S (for example, 16:55:15).                                                                                                                                                 |
| %U   | Represents the week of the year as a decimal number (00 to 53). Sunday, or its equivalent as defined by the <b>day</b> statement, is considered the first day of the week for calculating the value of this field descriptor. |
| %w   | Represents the day of the week as a decimal number (0 to 6). Sunday, or its equivalent as defined by the <b>day</b> statement, is considered as 0 for calculating the value of this field descriptor.                         |
| %W   | Represents the week of the year as a decimal number (00 to 53). Monday, or its equivalent as defined by the <b>day</b> statement, is considered the first day of the week for calculating the value of this field descriptor. |
| %x   | Represents the date format defined by the <b>d_fmt</b> statement.                                                                                                                                                             |
| %X   | Represents the time format defined by the <b>t_fmt</b> statement.                                                                                                                                                             |

| Item | Description                                                                                                                                                                                                                                                                                                                                                  |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %y   | Represents the year of the century (00 to 99).<br><b>Note:</b> When the environment variable <b>XPG_TIME_FMT=ON</b> , %y is the year within the century. When a century is not otherwise specified, values in the range 69-99 refer to years in the twentieth century (1969 to 1999, inclusive); values in the range 00-68 refer to 2000 to 2068, inclusive. |
| %Y   | Represents the year as a decimal number (for example, 1989).                                                                                                                                                                                                                                                                                                 |
| %Z   | Represents the time-zone name, if one can be determined (for example, EST); no characters are displayed if a time zone cannot be determined.                                                                                                                                                                                                                 |
| %%   | Specifies a % (percent sign) character.                                                                                                                                                                                                                                                                                                                      |

## Example

The following is an example of a possible **LC\_TIME** category listed in a locale definition source file:

```
LC_TIME
#
#Abbreviated weekday names (%a)
abday "<S><u><n>" ; "<M><o><n>" ; "<T><u><e>" ; "<W><e><d>" ; \
 "<T><h><u>" ; "<F><r><j>" ; "<S><a><t>"
#
#Full weekday names (%A)
day "<S><u><n><d><a><y>" ; "<M><o><n><d><a><y>" ; \
 "<T><u><e><s><d><a><y>" ; "<W><e><d><n><e><s><d><a><y>" ; \
 "<T><h><u><r><s><d><a><y>" ; "<F><r><i><d><a><y>" ; \
 "<S><a><t><u><r><d><a><y>" ;
#
#Abbreviated month names (%b)
abmon "<J><a><n>" ; "<F><e>" ; "<M><a><r>" ; "<A><p><r>" ; \
 "<M><a><y>" ; "<J><u><n>" ; "<J><u><l>" ; "<A><u><q>" ; \
 "<S><e><p>" ; "<O><c><t>" ; "<N><o><v>" ; "<D><e><c>" ;
#
#Full month names (%B)
mon "<J><a><n><u><a><r><y>" ; "<F><e><r><u><a><r><y>" ; \
 "<M><a><r><c><h>" ; "<A><p><r><i><l>" ; "<M><a><y>" ; \
 "<J><u><n><e>" ; "<J><u><l><y>" ; "<A><u><g><u><s><t>" ; \
 "<S><e><p><t><e><m><e><r>" ; "<O><c><t><o><e><r>" ; \
 "<N><o><v><e><m><e><r>" ; "<D><e><c><e><m><e><r>" ;
#
#Date and time format (%c)
d_t_fmt "%a %b %d %H:%M:%S %Y"
#
#Date format (%x)

## Locale Method Source File Format

### Purpose

Specifies the methods to be overridden when constructing a locale.

### Description

The **methods** source file maps methods names to the National Language Support (NLS) subroutines that implement those methods. The **methods** file also specifies the libraries where the implementing subroutines are stored.

The methods correspond to those subroutines that require direct access to the data structures representing locale data.

The following is the expected grammar for a **methods** file:

```
method_def : "METHODS"
 | method_assign_list "END METHODS"
 ;
method_assign_list :
 method_assign_list method_assign
 | method_assign_list

Where **cfunc\_name** is the name of a user supplied subroutine, and **meth\_lib\_path** is an optional path name for the library containing the specified subroutine.

**Note:** If a 64-bit locale is to be created, then **meth\_lib\_path** must specify the path for a single archive for the two shared objects, one 32-bit and the other 64-bit, containing the specified subroutines. Specifying separate paths to the 32-bit and 64-bit shared objects will result in **localedef** failing due to incompatible **XCOFF** format.

The **localedef** command parses this information to determine the methods to be used for this locale. The following subroutines must be specified in the **method** file:

- **\_mbtopc**
- **\_mbstopcs**
- **\_pctomb**
- **\_pcstombs**
- **mblen**
- **mbstowcs**
- **mbtowc**
- **wcstombs**
- **wcswidth**
- **wctomb**
- **wcwidth**

Any other method not specified in the **method** file retains the default.

Mixing of **cfunc\_name** values and **global\_name** values is not allowed. A **method** file should not include both. If the **localedef** command receives a **method** file containing both **cfunc\_name** values and **global\_name** values, an error is generated and the locale is not created.

It is not mandatory that the **METHODS** section specify the library name. If an individual method does not specify a library, the method inherits the most recently specified library. The **libc.a** library is the default library.

The method for the **mbtowc** and **wcwidth** subroutines should avoid calling other methods where possible.

An understanding of how the `_mbtopc`, `_mbstopcs`, `_pctomb`, and `_pcstombs` subroutines process wide characters is useful when constructing a **method** file. These subroutines should not be used in applications programs.

### `_mbtopc` Subroutine

The `_mbtopc` subroutine converts a character to a process code.

The syntax for the `_mbtopc` subroutine is as follows:

```
size_t __mbtopc(PC, S, LenS, Err) wchar_t * PC; uchar * S; size_t LenS; int * Err;
```

The input buffer pointed to by the *S* parameter contains the number of bytes of character data specified in the *LenS* parameter. The `_mbtopc` subroutine attempts to convert the character to a process code. If a valid character is found in the input buffer pointed to by the *S* parameter, the character is converted and stored in the *PC* parameter, and the number of bytes in the character is returned.

If the number of bytes specified by the *LenS* parameter in the input buffer pointed to by the *S* parameter form an invalid character, the subroutine returns 0 and sets the *Err* parameter to the value -1. If a character cannot be formed in the number of bytes specified by the *LenS* parameter or less, the subroutine returns 0 and sets the *Err* parameter to the number of bytes required to form a character beginning with the data pointed to by the *S* parameter.

The parameters have the following values:

| Item        | Description                                                                           |
|-------------|---------------------------------------------------------------------------------------|
| <i>PC</i>   | Points to a wide character to contain the converted character.                        |
| <i>S</i>    | Points to the buffer of character data to be converted.                               |
| <i>LenS</i> | Specifies the number of bytes of character data pointed to by the <i>S</i> parameter. |
| <i>Err</i>  | Specifies an error value indicating why the conversion failed.                        |

### `_mbstopcs` Subroutine

The `_mbstopcs` subroutine converts a character string to a process code string.

The syntax for the `_mbstopcs` subroutine is as follows:

```
size_t __mbstopcs(PC, LenPC, S, LenS, StopCh, EndPtr, Err) wchar_t * PC; size_t LenPC; uchar * S; size_t LenS; uchar StopCh; uchar ** EndPtr; int * Err;
```

The input buffer pointed to by the *S* parameter contains the number of bytes of character data specified in the *LenS* parameter. The `_mbstopcs` subroutine attempts to convert the character data to process codes. The conversion of characters continues until one of the following occurs:

- The number of bytes specified by the *LenS* parameter have been converted.
- The number of characters specified by the *LenPC* parameter have been converted.
- The byte value specified in the *StopCh* parameter is encountered in the input buffer pointed to by the *S* parameter.
- An invalid or incomplete character is found in the input buffer pointed to by the *S* parameter.

If the number of bytes specified by the *LenS* parameter or the number of characters specified by the *LenPC* parameter are successfully converted, the `_mbstopcs` subroutine returns the number of characters converted, sets the *Err* parameter to 0, and sets the *EndPtr* parameter to point immediately after the last character converted in the input buffer pointed to by the *S* parameter.

If the byte specified by the *StopCh* parameter is found in the input buffer pointed to by the *S* parameter, the following occurs:

- Conversion ceases.
- The value specified by the *StopCh* parameter is placed in the *PC* parameter.
- The *EndPtr* parameter is set to point immediately after the value specified by the *StopCh* parameter.
- The *Err* parameter is set to 0.
- The number of characters converted is returned.

If an invalid character is found in the input buffer pointed to by the *S* parameter, the *EndPtr* parameter is set to point to the start of this character, the *Err* parameter is set to `(size_t)-1`, and the `_mbstopcs` subroutine returns the number of characters converted.

If an incomplete character is found at the end of the input buffer pointed to by the *S* parameter, the *EndPtr* parameter is set to point to the start of the incomplete character, and the *Err* parameter is set to the number of bytes in a character starting with the byte pointed to by *EndPtr* parameter. The `_mbstopcs` subroutine returns the number of characters converted.

The parameters have the following values:

| Item          | Description                                                                                    |
|---------------|------------------------------------------------------------------------------------------------|
| <i>PC</i>     | Points to a <code>wchar_t</code> array to contain the converted characters.                    |
| <i>LenPC</i>  | Specifies the maximum number of wide characters that can be placed in the <i>PC</i> parameter. |
| <i>S</i>      | Points to a buffer of character data to be converted.                                          |
| <i>LenS</i>   | Specifies the number of bytes of character data in the <i>S</i> parameter.                     |
| <i>StopCh</i> | Specifies a single-byte character value to indicate end of data in the <i>S</i> parameter.     |
| <i>EndPtr</i> | Points into the <i>S</i> parameter where character conversion ended.                           |
| <i>Err</i>    | Specifies an error value indicating why the conversion failed.                                 |

### **`_pctomb` Subroutine**

The `_pctomb` subroutine converts a process code to a character.

The syntax for the `_pctomb` subroutine is as follows:

```
size_t _pctomb(S, LenS, PC, Err) char * S; size_t LenS; wchar_t * PC; int * Err;
```

The input buffer pointed to by the *PC* parameter contains a wide character that the subroutine attempts to convert to a character in the input buffer pointed to by the *S* parameter. If a valid process code is found in the input buffer pointed to by the *PC* parameter, it is converted and stored in the input buffer pointed to by the *S* parameter, and the number of bytes in the character is returned.

If the wide character in the input buffer pointed to by the *PC* parameter is invalid, the `_pctomb` subroutine returns 0 and sets the *Err* parameter to the value `(size_t)-1`. If the length of the character is greater than the number of bytes specified by the *LenS* parameter, the `_pctomb` subroutine returns 0 and sets the *Err* parameter to the number of bytes required to form the character.

The parameters have the following values:

| Item        | Description                                                                     |
|-------------|---------------------------------------------------------------------------------|
| <i>S</i>    | Points to a buffer to contain the converted process code.                       |
| <i>LenS</i> | Specifies the size of the character array pointed to by the <i>S</i> parameter. |
| <i>PC</i>   | Points to the wide character to be converted.                                   |
| <i>Err</i>  | Specifies an error value indicating why the conversion failed.                  |

### **\_\_pcstombs Subroutine**

The **\_\_pcstombs** subroutine converts a wide character string to a character string.

The syntax for the **\_\_pcstombs** subroutine is as follows:

```
size_t __pcstombs(S, LenS, PC, LenPC, StopCh, EndPtr, Err) char * S; size_t LenS; wchar_t * PC; size_t
LenPC; wchar_t StopCh; char ** EndPtr; int * Err;
```

The input buffer pointed to by the *PC* parameter contains the number of wide characters specified by the *LenPC* parameter. The **\_\_pcstombs** subroutine attempts to convert the process codes to characters. The conversion continues until one of the following occurs:

- The number of wide characters specified by the *LenPC* parameter have been converted.
- The number of bytes specified by the *LenS* parameter have been converted.
- The character value specified in the *StopCh* parameter is encountered in the input buffer pointed to by the *PC* parameter.
- An invalid wide character is found in the input buffer pointed to by the *PC* parameter.

If the number of bytes specified by the *LenS* parameter or the number of characters specified by the *LenPC* parameter are successfully converted, the **\_\_pcstombs** subroutine returns the number of bytes placed in the buffer pointed to by the *S* parameter, sets the *Err* parameter to 0, and sets the *EndPtr* parameter to point immediately after the last character converted in the input buffer pointed to by the *PC* parameter.

If the character specified by the *StopCh* parameter is found in the input buffer pointed to by the *PC* parameter, the following occurs:

- Conversion ceases.
- The character specified by the *StopCh* parameter is placed at the end of the data currently pointed to by the *S* parameter.
- The *EndPtr* parameter is set to point immediately after the character specified by the *StopCh* parameter.
- The *Err* parameter is set to 0.
- The number of bytes placed in the buffer pointed to by the *S* parameter is returned.

If an invalid wide character is found in the input buffer pointed to by the *PC* parameter, the *EndPtr* parameter is set to point to the start of this character, the *Err* parameter is set to **(size\_t)-1**, and the **\_\_pcstombs** subroutine returns the number of bytes placed in the buffer pointed to by the *S* parameter.

The parameters have the following values:

| <b>Item</b>   | <b>Description</b>                                                                                           |
|---------------|--------------------------------------------------------------------------------------------------------------|
| <i>S</i>      | Points to a buffer to contain the converted data.                                                            |
| <i>LenS</i>   | Specifies the size in bytes of the character array pointed to by the <i>S</i> parameter.                     |
| <i>PC</i>     | Points to a <b>wchar_t</b> array to be converted.                                                            |
| <i>LenPC</i>  | Specifies the number of wide characters in the array pointed to by the <i>PC</i> parameter.                  |
| <i>StopCh</i> | Specifies a wide-character value to indicate end of data in the array pointed to by the <i>PC</i> parameter. |
| <i>EndPtr</i> | Points into the <i>S</i> parameter where character conversion ended.                                         |
| <i>Err</i>    | Specifies the error value indicating why the conversion failed.                                              |

## Files

| <b>Item</b>                         | <b>Description</b>                                                                         |
|-------------------------------------|--------------------------------------------------------------------------------------------|
| <code>/usr/lib/nls/loc/*</code>     | Specifies locale definition source files for supported locales.                            |
| <code>/usr/lib/nls/charmap/*</code> | Specifies character set description ( <b>charmap</b> ) source files for supported locales. |

## magic File Format

### Purpose

Defines file types.

### Description

The **/etc/magic** file is used by commands such as the following to determine the type of a given file:

- **file** command
- **more** command

Entering the following command would result in a printed message describing the file type of the *FileName* parameter:

```
file FileName
```

If *FileName* contains a byte pattern corresponding to an executable file, the pattern would match a stanza in the **/etc/magic** file and the executable message would be displayed. If the *FileName* is a data file, a data message is displayed, and so on.

The fields of the magic file are as follows:

1. Byte offset
2. Value type
3. Optional relational operator ("=" by default) and value to match (numeric or string constant)
4. String to be printed

Numeric values may be decimal, octal, or hexadecimal. Strings can be entered as hexadecimal values by preceding them with '0x'.

The last string can have one **printf** format specification.

The > (greater than) symbol in occasional column 1s is magic; it forces commands to continue scanning and matching additional lines. The first line not marked with the > sign terminates the search.

## Examples

```
0 short 2345 this is a dummy type file
0 long 0x1234 this is a different dummy type file
>12 long >0 another possible type
0 short 7895 last type of file
```

## .mailrc File Format

### Purpose

Sets defaults for the **mail** command.

### Description

The **.mailrc** file can be placed in your **\$HOME** directory to personalize the **Mail** program. You can create the **.mailrc** file with any ASCII editor. Once the file is created, the **Mail** program reads the file when you send or read mail, and applies the options you have set. In the file, you can define aliases for other users' mail addresses. You can also change the way mail is displayed and stored on your system.

The **Mail** program uses a master file in the same format, **/usr/share/lib/Mail.rc**. Options you set in your **\$HOME/.mailrc** file override comparable options in the **Mail.rc** file.

A line that begins with a # (pound sign) followed by a space is treated as a comment. The **Mail** program ignores the entire line and any entries or options it contains.

### Entries

Use the following **mail** subcommands as entries in the **.mailrc** file:

| <b>mail Subcommand</b>                                                       | <b>Definition</b>                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>alias</b> <i>NewAlias</i> { <i>Address...</i>   <i>PreviousAlias...</i> } | Defines an alias or distribution list. The alias can be defined as an actual mail address, or as another alias defined in a previous entry in the <b>.mailrc</b> file. To define a group, enter multiple addresses or previous aliases separated by spaces.                                                                                                                              |
| <b>ignore</b> <i>FieldList</i>                                               | Adds the header fields in the <i>FieldList</i> parameter to the list of fields to be ignored. Ignored fields are not displayed when you look at a message with the <b>type</b> or <b>print</b> subcommand. Use this subcommand to suppress machine-generated header fields. Use the <b>Type</b> or <b>Print</b> subcommand to print a message in its entirety, including ignored fields. |
| <b>set</b> [ <i>OptionList</i>   <i>Option=Value...</i> ]                    | Sets an option. The argument following the <b>set</b> option can be either an <i>OptionList</i> giving the name of a binary option (an option that is either set or unset) or an <i>Option=Value</i> entry used to assign a value to an option.                                                                                                                                          |
| <b>unset</b> <i>OptionList</i>                                               | Disables the values of the options specified in <i>OptionList</i> . This action is the inverse of the <b>set</b> <i>OptionList</i> entry.                                                                                                                                                                                                                                                |

### Binary Options for the **set** and **unset** Entries

Use the **set** entry to enable options and the **unset** entry to disable options. Add the options you want to set or unset to the **\$HOME/.mailrc** file. The options and the actions they generate are as follows:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>append</b>    | Adds messages saved in your mailbox to the end rather than to the beginning of the <b>\$HOME/mbox</b> file.                                                                                                                                                                                                                                                                             |
| <b>ask</b>       | Prompts for the subject of each message sent. If you do not wish to create a subject field, press the Enter key at the prompt.                                                                                                                                                                                                                                                          |
| <b>askcc</b>     | Prompts for the addresses of people who should receive copies of the message. If you do not wish to send copies, press the Enter key at the prompt.                                                                                                                                                                                                                                     |
| <b>autoprint</b> | Sets the <b>delete</b> subcommand to delete the current message and display the next message.                                                                                                                                                                                                                                                                                           |
| <b>debug</b>     | Displays debugging information. Messages are not sent while in debug mode. This is the same as specifying the <b>-d</b> flag on the command line.                                                                                                                                                                                                                                       |
| <b>dot</b>       | Interprets a period entered on a line by itself as the end of a message you are sending.                                                                                                                                                                                                                                                                                                |
| <b>hold</b>      | Holds messages that you have read but have not deleted or saved in the system mailbox instead of in your personal mailbox. This option has no effect on deleted messages.                                                                                                                                                                                                               |
| <b>ignore</b>    | Ignores interrupt messages from your terminal and echoes them as @ (at sign) characters.                                                                                                                                                                                                                                                                                                |
| <b>ignoreeof</b> | Sets the <b>mail</b> command to refuse the Ctrl-D key sequence as the end of a message.                                                                                                                                                                                                                                                                                                 |
| <b>keepsave</b>  | Prevents the Mail program from deleting messages that you have saved with the <b>s</b> or <b>w</b> mailbox subcommand. Normally, messages are deleted automatically when you exit the <b>mail</b> command. Use the <b>keepsave</b> and <b>hold</b> options to hold messages in your system mailbox. Otherwise, the messages are placed in your personal mailbox ( <b>\$HOME/mbox</b> ). |
| <b>metoo</b>     | Includes the sender in the alias expansion. By default, expanding the alias removes the sender. When this option is set in your <b>.mailrc</b> file, sending a message using an alias that includes your name sends a copy of the message to your mailbox.                                                                                                                              |
| <b>noheader</b>  | Suppresses the list of messages in your mailbox when you start the Mail program. Instead, only the mailbox prompt (&) is displayed. To get a list of messages, use the <b>h</b> mailbox subcommand.                                                                                                                                                                                     |
| <b>nosave</b>    | Prevents retention of interrupted letters in the <b>\$HOME/dead.letter</b> file.                                                                                                                                                                                                                                                                                                        |
| <b>quiet</b>     | Suppresses the printing of the banner when the Mail program starts. The banner is the line that shows the name of the Mail program.                                                                                                                                                                                                                                                     |
| <b>Replyall</b>  | Reverses the meaning of the <b>reply</b> subcommand and the <b>Reply</b> subcommand.                                                                                                                                                                                                                                                                                                    |
| <b>verbose</b>   | Displays the actual delivery of messages on the terminal. This is the same as specifying the <b>-v</b> flag on the command line.                                                                                                                                                                                                                                                        |

## Value Options for the **set** Entry

You can use a **set** entry to assign values to the following options. For example, enter **set screen=20** to limit headers to 20 lines per screen.

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>crt=Lines</b>        | Defines the number of lines of a mail message the Mail program displays before pausing for input (this option starts the <b>pg</b> command to control the scrolling).                                                                                                                                                                                                                                 |
| <b>EDITOR=Editor</b>    | Gives the full path name of the editor to be started with the <b>e</b> mailbox subcommand or the <b>~e</b> mail editor subcommand. The default editor is <b>/usr/bin/e</b> .                                                                                                                                                                                                                          |
| <b>escape=Character</b> | Changes the escape character used for mail editor subcommands. The default character is ~ (tilde).                                                                                                                                                                                                                                                                                                    |
| <b>folder=PathName</b>  | Gives the path name of a directory in which to store mail folders. Once the directory is defined, you can use the + (plus sign) notation to refer to it when using the <i>FileName</i> parameter with mailbox subcommands.                                                                                                                                                                            |
| <b>record=FileName</b>  | Defines a file in which to record outgoing mail. The path name must be absolute (that is, a full path name), or be given relative to the current directory.<br><b>Note:</b> If you set up a file to record outgoing messages, read the file periodically with the <b>mail -f</b> command and delete unnecessary messages. Otherwise, the file will grow and eventually use all of your storage space. |
| <b>screen=Lines</b>     | Defines the number of lines of message headers displayed (for example, in response to the <b>h</b> mailbox subcommand) before pausing for input.                                                                                                                                                                                                                                                      |
| <b>toplines=Lines</b>   | Defines the number of lines displayed by the <b>top</b> mailbox subcommand.                                                                                                                                                                                                                                                                                                                           |
| <b>VISUAL=Editor</b>    | Gives the full path name of the editor to be started with the <b>v</b> mailbox subcommand or the <b>~v</b> mail editor subcommand. The default editor is <b>/usr/bin/vi</b> .                                                                                                                                                                                                                         |

## Examples

1. To ignore the Message-ID field and the Received field, place the following entry in the **.mailrc** file:

```
ignore message-id received
```

When messages are displayed in the mailbox, the machine message ID number and the date your system received the message are not displayed.

2. To set a folder directory, place the following entry in the **.mailrc** file:

```
set folder=/home/kaye/notes
```

To save message 1 from the mailbox in the folder procedures, enter the following at the mailbox prompt (&):

```
s 1 +procedure
```

Message 1 is saved in the `/home/kaye/notes/procedures` file (if the file already exists, the message is appended to the file).

3. To record outgoing mail in a folder directory, place the following pair of entries in the **.mailrc** file:

```
set record=/home/pierre/letters/mailout
set folder=/home/pierre/letters
```

Outgoing mail is placed in the `/home/pierre/letters/mailout` file, and can be read with the following command:

```
mail -f +mailout
```

4. To combine the delete and print commands and also instruct the Mail program to include your user ID when expanding aliases, enter the following in your **.mailrc** file:

```
set autoprint metoo
```

The **autoprint** option causes the next message to be displayed whenever you delete a message. The **metoo** option causes the Mail program to send a copy of messages to you when it expands mail aliases. By default, the Mail program discards your user address when it expands an alias, so that you do not get a copy of mail you send.

5. To unset an option that is set in the `/usr/share/lib/Mail.rc` file, enter the following in your **.mailrc** file:

```
unset askcc
```

This entry prevents the mail editor from requesting a carbon copy list when you create messages, even if the **askcc** option is set in the `Mail.rc` file.

6. To set aliases for two users and a distribution list that includes several users, enter the following in your **.mailrc** file:

```
alias george george@thor.valhalla.dbm.comm
alias bill @odin.UUCP:@depta.UCCP:@deptb:bill@deptc
alias mygroup amy@cleo george bill
```

To send mail to user `bill` using his alias, enter:

```
mail bill
```

To send mail to everyone in the `mygroup` list, enter:

```
mail mygroup
```

When you complete and send the message, the **mail** command actually addresses it as follows:

```
amy@cleo george@thor.valhalla.dbm.comm @odin.UUCP:@depta.UCCP:
@deptb:bill@deptc
```

## Files

| Item                   | Description                                           |
|------------------------|-------------------------------------------------------|
| /usr/share/lib/Mail.rc | Contains systemwide defaults for the Mail program.    |
| \$HOME/.mailrc         | Contains user-specific defaults for the Mail program. |

## map3270 File Format for TCP/IP

### Purpose

Defines keyboard mapping and colors for the **tn3270** command.

### Description

The **/etc/map3270** file defines keyboard mapping and colors for the **tn3270** command. When emulating 3270 terminals, mapping must be performed between key sequences entered on a user's (ASCII) keyboard and the keys that are available on a 3270 emulator.

For example, the 3270 emulator key **EEOF** erases the contents of the current field from the location of the cursor to the end of the field. In order to accomplish this function, the terminal user and a program emulating a 3270 emulator must be compatible with regard to what keys invoke the **EEOF** function.

The requirements for these sequences are:

- The first character of the sequence is outside of the standard ASCII printable characters.
- No one sequence is an initial part of another (although sequences may share initial parts).

The **/etc/map3270** file consists of entries for various terminals. The first part of an entry lists names of terminals using that entry. These names should be the same as those in the **/usr/share/lib/terminfo/\*.ti** files.

**Note:** Often, several terminals from different **/usr/share/lib/terminfo/\*.ti** entries use the same **/etc/map3270** file entry. For example, both 925 and 925vb (for 925 with visual bells) might use the same **map3270** file entry. Each name is separated by a | (vertical bar), after which comes a { (left brace); the definitions; and finally, a } (right brace).

### Format

The definitions begin with a reserved keyword, which identifies the 3270 function. The keyword is followed by an = (equal sign), which in turn is followed by the various string sequences to generate the particular function. The definitions end with a ; (semi-colon). The string sequences are printable ASCII characters enclosed inside '' (single quotes) and separated by | (vertical bars).

Special characters can be used within '' (single quotes). A ^ (caret) indicates a control character. For example, the string '^a' represents Ctrl-A; that is, hexadecimal 1 (the string '^A' generates the same code). To generate delete or rubout, enter '^d' '^?' (Ctrl-D or Ctrl-?). To represent a control character in the **/etc/map3270** file, you must use the caret. Typing Control-A or Ctrl-A does not work.

**Note:** The Ctrl-^ key sequence (to generate a hexadecimal 1E) is represented as '^'^ (not '^\\^').

The \ (backslash) special character precedes other characters to change their meaning. Because this has little effect for most characters, its use is not recommended. The backslash prevents a single quote from terminating a string, for example the string '^\\' represents Ctrl-. For a backslash to be part of a string, place two backslashes ('\\') in the string.

In addition, the following characters are special:

- '\e' Specifies an escape character.
- '\n' Specifies a new line.
- '\t' Specifies a tab.
- '\r' Specifies a carriage return.

It is not necessary for each character in a string to be enclosed within single quotes. The string '\e\e\e' means three escape characters.

Comments, which may appear anywhere on a line, begin with a # (pound sign) and terminate at the end of that line. However, comments cannot begin inside a quoted string. A pound sign inside a quoted string has no special meaning.

## 3270 Keys Supported

**Note:** Some of the following keys do not exist on a 3270 emulator. The functions listed with an \* (asterisk) are not supported by the **tn3270** command. An unsupported function causes the **tn3270** command to send a bell sequence to the user's terminal.

The /etc/map3270 file supports the following list of 3270 key names:

| Key Name  | Functional Description                                                                                                                                                                        |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| altk*     | Alternate keyboard dvorak                                                                                                                                                                     |
| aplend*   | Treat input as ASCII                                                                                                                                                                          |
| aploff*   | APL off                                                                                                                                                                                       |
| aplon*    | APL on                                                                                                                                                                                        |
| attention | Attention key. The attention key sends an IAC BREAK TELNET protocol sequence to the TELNET server on a VM or MVS system. The TELNET server is responsible for implementing the attention key. |
| btab      | Field tab back                                                                                                                                                                                |
| clear     | Local clear of the 3270 screen                                                                                                                                                                |
| clrtab    | Clear all column tabs                                                                                                                                                                         |
| colbak    | Column back tab                                                                                                                                                                               |
| coltab    | Column tab                                                                                                                                                                                    |
| cursor*   | Cursor select                                                                                                                                                                                 |
| delete    | Delete character                                                                                                                                                                              |
| deltab    | Delete a column tab                                                                                                                                                                           |
| disc      | Disconnect (suspend)                                                                                                                                                                          |
| down      | Down cursor                                                                                                                                                                                   |
| dp        | Duplicate character                                                                                                                                                                           |
| eof       | Erase end of field                                                                                                                                                                            |
| einp      | Erase input                                                                                                                                                                                   |
| enter     | Enter key                                                                                                                                                                                     |
| erase     | Erase last character                                                                                                                                                                          |
| escape    | Enter TELNET command mode                                                                                                                                                                     |
| ferase    | Erase field                                                                                                                                                                                   |
| fieldend  | Tab to last non-blank of current or next unprotected (writable) field                                                                                                                         |
| flinp     | Flush input                                                                                                                                                                                   |
| fm        | Field mark character                                                                                                                                                                          |
| home      | Home the cursor                                                                                                                                                                               |
| indent    | Indent one tab stop                                                                                                                                                                           |
| init*     | New terminal type                                                                                                                                                                             |
| insrt     | Toggle insert mode                                                                                                                                                                            |

| <b>Item</b>         | <b>Description</b>                       |
|---------------------|------------------------------------------|
| <b>left</b>         | Left cursor                              |
| <b>lpri*</b>        | Local print                              |
| <b>master_reset</b> | Reset, unlock, and redisplay             |
| <b>nl</b>           | New line                                 |
| <b>pa1</b>          | Program attention 1                      |
| <b>pa2</b>          | Program attention 2                      |
| <b>pa3</b>          | Program attention 3                      |
| <b>pfk1</b>         | Program function key 1                   |
| <b>pfk2</b>         | Program function key 2                   |
| .                   | .                                        |
| .                   | .                                        |
| .                   | .                                        |
| <b>pfk36</b>        | Program function key 36.                 |
| <b>pcoff*</b>       | Xon/xoff off                             |
| <b>pcon*</b>        | Xon/xoff on                              |
| <b>reset</b>        | Reset key-unlock keyboard                |
| <b>reshow</b>       | Redisplay the screen                     |
| <b>right</b>        | Right cursor                             |
| <b>sethom</b>       | Set home position                        |
| <b>setmrg</b>       | Set left margin                          |
| <b>settab</b>       | Set a column tab                         |
| <b>synch</b>        | In synch with the user                   |
| <b>tab</b>          | Field tab                                |
| <b>treq</b>         | Test request                             |
| <b>undent</b>       | Undent one tab stop                      |
| <b>up</b>           | Up cursor                                |
| <b>werase</b>       | Erase last word                          |
| <b>wordbacktab</b>  | Tab to beginning of current or last word |
| <b>wordend</b>      | Tab to end of current or next word       |
| <b>wordtab</b>      | Tab to beginning of next word            |
| <b>xoff*</b>        | Hold output                              |
| <b>xon*</b>         | Release output                           |

## A Sample Entry

The following default entry is included within the **tn3270** command and is used when it is unable to locate a version in the user's environment or the **/etc/map3270** file.

```

name { # actual name comes from TERM variable
clear = '^z';
flinp = '^x';
enter = '^m';
delete = '^d' | '^?'; # note that '^?' is delete (rubout)
synch = '^r';
reshow = '^v';
eof = '^e';
tab = '^j';
btab = '^b';

nl = '^n';
left = '^h';
right = '^l';
up = '^k';
down = '^j';
einp = '^w';
reset = '^t';
xoff = '^s';
xon = '^q';
escape = '^c';
ferase = '^u';

```

```

insrt = ' ';
program attention keys
pa1 = '^p1'; pa2 = '^p2'; pa3 = '^p3';
program function keys
pfk1 = '1'; pfk2 = '2'; pfk3 = '3'; pfk4 = '4';
pfk5 = '5'; pfk6 = '6'; pfk7 = '7'; pfk8 = '8';
pfk9 = '9'; pfk10 = ' ' ; pfk11 = '-' ; pfk12 = '=' ;
pfk13 = '' ; pfk14 = '@' ; pfk15 = '0';
pfk17 = '' ; pfk18 = '' ; pfk19 = '' ; pfk20 = ' ';
pfk21 = ' ' ; pfk22 = ')' ; pfk23 = '_' ; pfk24 = ' ' ;
}

```

## 3270 Key Definitions

The following table shows the proper keys to emulate each 3270 function when using the default key mapping supplied with the **tn3270** command.

*Table 5. 3270 Key Definitions*

| Function             | 3270 Key     | Default Key(s)      |
|----------------------|--------------|---------------------|
| Command Keys         | Enter        | RETURN              |
|                      | Clear        | Ctrl-z              |
|                      | Attention    | Ctrl-F12            |
| Cursor Movement Keys | New line     | Ctrl-n or Home      |
|                      | Tab          | Ctrl-i              |
|                      | Back tab     | Ctrl-b              |
|                      | Cursor left  | Ctrl-h              |
|                      | Cursor right | Ctrl-l              |
|                      | Cursor up    | Ctrl-k              |
|                      | Cursor down  | Ctrl-j or LINE FEED |
| Edit Control Keys    | Delete char  | Ctrl-d or RUB       |
|                      | Erase EOF    | Ctrl-e              |
|                      | Erase input  | Ctrl-w              |
|                      | Insert mode  | ESC Space           |
|                      | End insert   | ESC Space           |

| Item                   | Description        |          |
|------------------------|--------------------|----------|
| Program Function Keys  | PF1                | ESC 1    |
|                        | PF2                | ESC 2    |
|                        | ...                | ...      |
|                        | PF10               | ESC 0    |
|                        | PF11               | ESC -    |
|                        | PF12               | ESC =    |
|                        | PF13               | ESC !    |
|                        | PF14               | ESC @    |
|                        | ...                | ...      |
|                        | PF24               | ESC +    |
| Program Attention Keys | PA1                | Ctrl-p 1 |
|                        | PA2                | Ctrl-p 2 |
|                        | PA3                | Ctrl-p 3 |
| Local Control Keys     | Reset after error  | Ctrl-r   |
|                        | Purge input buffer | Ctrl-x   |

| Item       | Description         |        |
|------------|---------------------|--------|
|            | Keyboard unlock     | Ctrl-t |
|            | Redisplay screen    | Ctrl-v |
| Other Keys | Erase current field | Ctrl-u |

## Files

| Item                         | Description                            |
|------------------------------|----------------------------------------|
| /etc/3270.keys               | Contains the default keyboard mapping. |
| /usr/share/lib/terminfo/*.ti | Files containing terminal information. |

## Maxuuscheds File Format for BNU

### Purpose

Limits the number of instances of the **uusched** and **uucico** daemons that can run simultaneously.

### Description

The **/etc/uucp/Maxuuscheds** file limits the number of instances of the Basic Networking Utilities (BNU) **uusched** daemons that can run simultaneously. Since each instance of the **uusched** daemon is associated with one instance of the **uucico** daemon, the file limits the instances of the **uucico** daemon in a similar way. This file is used in conjunction with the lock files in the **/etc/locks** directory to determine the number of systems currently being polled. Use this file to help manage system resources and load averages.

The **Maxuuscheds** file contains an ASCII number that can be changed for your installation. The default is 2. The larger the number, the greater the potential load on the local system. In any case, the limit should always be less than the number of outgoing lines used by BNU.

The **Maxuuscheds** file requires neither configuration nor maintenance, unless the system on which it is installed is contacted frequently and heavily by users on remote systems.

## Files

| Item                 | Description                                                                              |
|----------------------|------------------------------------------------------------------------------------------|
| /etc/locks directory | Contains lock files that prevent multiple uses of devices and multiple calls to systems. |
| /etc/uucp directory  | Contains some of the configuration files for BNU, including the <b>Maxuuscheds</b> file. |

## **Maxuuxqts File Format for BNU**

### **Purpose**

Limits the number of instances of the BNU **uuxqt** daemon that can run simultaneously on the local system.

### **Description**

The **/etc/uucp/Maxuuxqts** file limits both the number of instances of the Basic Networking Utilities (BNU) **uuxqt** daemon that can run simultaneously on the local system and the number of commands from remote systems that can run at one time.

This file contains an ASCII number that can be changed for your installation. The default value is 2. The larger the number, the greater the potential load on the local system.

The **Maxuuxqts** file requires neither configuration nor maintenance, unless the system on which it is installed is used frequently and heavily by users on remote systems.

### **Files**

| Item                       | Description                                                                            |
|----------------------------|----------------------------------------------------------------------------------------|
| <b>/etc/uucp</b> directory | Contains some of the configuration files for BNU, including the <b>Maxuuxqts</b> file. |

## **.mh\_alias File Format**

### **Purpose**

Defines aliases.

### **Description**

An alias file contains lines that associate an alias name with an address or group of addresses. The Message Handler (MH) package reads both personal alias files (customarily the **\$HOME/.mh\_alias** file) and a systemwide alias file, the **/etc/mh/MailAliases** file. Depending on the MH configuration, aliases may also be defined in the **/etc/aliases** file (see the **sendmail** command).

The alias file name is an argument to several MH commands. These commands can be set automatically by entries in the **.mh\_profile** file. Personal alias files can have any name, but must follow the format described here. The **/etc/mh/MailAliases** file is the default alias file for systemwide aliases. This file is set up by a user with root user authority.

Specify your personal alias file in your **.mh\_profile** file. Otherwise, you must use the **-alias** flag each time you use an MH command that requires this flag.

Each line of an **.mh\_alias** file has one of the following formats:

- *Alias : Address-Group*
- *Alias ; Address-Group*
- <Alias-File>

The variables are described as follows:

| Item              | Description                                                                                                                        |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <i>Alias</i>      | Specifies a simple address.                                                                                                        |
| <i>Address</i>    | Specifies a simple Internet-style address.                                                                                         |
| <i>Group</i>      | Specifies a group name (or number) from the <i>/etc/group</i> file.                                                                |
| <i>Alias-File</i> | Specifies a system file name. The MH package treats alias file names as case-sensitive. Alias expansion is case-sensitive as well. |

The *Address-Group* variable can be either of the following:

| Item                  | Description                                        |
|-----------------------|----------------------------------------------------|
| <i>AddressList</i>    | List of addresses that make up a group.            |
| <i>&lt;Alias-File</i> | System file to be read for more alias definitions. |

The addresses in the *AddressList* variable must be separated by commas.

**Note:** If there are references to aliases within an alias definition, those aliases must be defined in a following line of the alias file.

## Special Characters

| Item          | Description                                                                                                                                                                                                                                                    |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \ (backslash) | You can continue an alias definition on the next line by ending the line to be continued with a \ (backslash) followed by a new-line character.                                                                                                                |
| < (less than) | If a line starts with a < (less-than sign), MH reads the file specified after the less-than sign for more alias definitions. The reading is done recursively.                                                                                                  |
| = (equal)     | If an address group starts with a < (less-than sign), MH reads the file specified after the less-than sign and adds the contents of that file to the address list for the alias.                                                                               |
| + (plus)      | If an address group starts with an = (equal sign), MH consults the <i>/etc/group</i> file for the group specified after an equal sign. The MH package adds each login name occurring as a member of the group to the address list for the alias.               |
| * (asterisk)  | If an address group starts with a + (plus sign), MH consults the <i>/etc/group</i> file to determine the ID of the group. Each login name appearing in the <i>/etc/passwd</i> file that matches the address group is added to the address list for the alias.  |
|               | If an address group is defined by an * (asterisk), MH consults the <i>/etc/passwd</i> file and adds all login names with a user number greater than 200 (or the value set for everyone in the <i>/etc/mh/mstailor</i> file) to the address list for the alias. |

The following list explains how the system resolves aliases at posting time:

1. The system builds a list of all addresses from the message to be delivered, eliminating duplicate addresses.
2. If the draft originated on the local host, the system performs alias resolution for addresses that have no specified host.
3. For each line in the alias file, the system compares the alias with all existing addresses. If a match is found, the system removes the matched alias from the address list. The system then adds each new address in the address group to the address list. The alias itself is not usually output. Instead, the address group to which the alias maps is output. If the alias is terminated with a ; (semicolon) instead of a : (colon), both the alias and the address are output in the correct form. (This correct form makes replies possible since MH aliases and personal aliases are unknown to the mail transport system.)

In pattern matching, a trailing \* (asterisk) in an alias matches just about anything appropriate.

## Examples

The following example of an **.mh\_alias** file illustrates some of its features:

```

</home/sarah/morealiases
systems:= systems
staff:+ staff
everyone:+*
manager: harold@harold
project:lance,mark@remote,peter,manager

```

The first line says that more aliases should be read from the `/home/sarah/morealiases` file. The `systems` alias is defined as all users listed as members of the group `systems` in the `/etc/group` file. The `staff` alias is defined as all users whose group ID in the `/etc/passwd` file is equivalent to the `staff` group. Finally, the `everyone` alias is defined as all users with a user ID in the `/etc/passwd` file greater than 200.

The `manager` alias is defined as an alias for user `harold@harold`. The `project` alias is defined as the users `lance`, `mark@remote`, `peter`, and `manager`.

## Files

| Item                             | Description                                                                                                               |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/aliases</code>        | Contains systemwide aliases for the <code>sendmail</code> command.                                                        |
| <code>/etc/group</code>          | Contains basic group attributes.                                                                                          |
| <code>/etc/passwd</code>         | Contains user authentication information.                                                                                 |
| <code>/etc/mh/MailAliases</code> | Contains the <code>defaults</code> alias file for systemwide aliases, which is set up by a user with root user authority. |
| <code>/etc/mh/mtstailor</code>   | Tailors the Message Handler (MH) environment to the local environment.                                                    |
| <code>.mh_profile</code>         | Customizes the Message Handler (MH) package.                                                                              |

## mib.defs File Format

### Purpose

Provides descriptions of Management Information Base (MIB) variables for the `snmpinfo` command.

### Description

The `mib.defs` file provides object descriptions of MIB variables for the `snmpinfo` command issued with the `get`, `next`, `set`, and `dump` options. See the `snmpinfo` command for more information. This command is part of Simple Network Management Protocol Agent Applications in Network Support Facilities.

The `mib.defs` file is not intended to be edited by the user. The file should be created with the `mosy` command. See the `mosy` command for information on how to create the `mib.defs` file. This file has the following format:

The MIB group fields are separated by spaces or tabs and contain the following information:

| <b>Item</b>            | <b>Description</b>                                                                                                                                                                                              |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>GroupDescriptor</i> | Holds the textual name of the MIB group.                                                                                                                                                                        |
| <i>GroupEntry</i>      | Denotes the parent MIB group and the location of this MIB group in the parent group. This field is used by the <b>snmpinfo</b> command to resolve the ASN.1 dotted notation for MIB variables under this group. |

The MIB groups are defined as follows:

| <b>Group Descriptor</b> | <b>Group Entry</b> |
|-------------------------|--------------------|
| <b>internet</b>         | <b>iso.3.6.1</b>   |
| <b>directory</b>        | <b>internet.1</b>  |
| <b>mgmt</b>             | <b>internet.2</b>  |
| .                       | .                  |
| .                       | .                  |
| .                       | .                  |
| <b>mib-2</b>            | <b>mgmt.1</b>      |
| <b>system</b>           | <b>mib-2.1</b>     |
| .                       | .                  |
| .                       | .                  |

The object definitions of MIB variables are formatted as follows:

| <b>Object Descriptor</b> | <b>Group Entry</b> | <b>Syntax</b>        | <b>Access</b>    | <b>Status</b>    |
|--------------------------|--------------------|----------------------|------------------|------------------|
| <i>sysDescr</i>          | <b>system.1</b>    | <b>DisplayString</b> | <b>read-only</b> | <b>mandatory</b> |

The MIB variable fields are separated by spaces or tabs, and contain the following information:

| <b>Item</b>             | <b>Description</b>                                                                                                                                                                                                                                                                              |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>ObjectDescriptor</i> | Holds the textual name of the object.                                                                                                                                                                                                                                                           |
| <i>GroupEntry</i>       | Denotes the MIB object group and the location of this MIB variable in this group. This field is used by the <b>snmpinfo</b> command to resolve the ASN.1 dotted notation for this MIB variable.                                                                                                 |
| <i>Syntax</i>           | Denotes the type of the object as one of the following: <ul style="list-style-type: none"> <li>• INTEGER</li> <li>• OCTET STRING or DisplayString</li> <li>• OBJECT IDENTIFIER</li> <li>• Network Address</li> <li>• Counter</li> <li>• Gauge</li> <li>• TimeTicks</li> <li>• Opaque</li> </ul> |
| <i>Access</i>           | Designates the access permissions for the object and can be one of the following: <ul style="list-style-type: none"> <li>• Read-only</li> <li>• Read-write</li> <li>• Write-only</li> <li>• Not-accessible</li> </ul>                                                                           |
| <i>Status</i>           | Designates the RFC 1213 compliance status of the object and can be one of the following: <ul style="list-style-type: none"> <li>• Mandatory</li> <li>• Optional</li> <li>• Deprecated</li> <li>• Obsolete</li> </ul>                                                                            |

The parent MIB group definition required for a particular MIB variable *GroupEntry* definition must precede the object definition for the MIB variable.

Comments begin with a # (pound sign) or - - (two dashes) and continue to the end of the line.

## Files

| Item                        | Description                                                                    |
|-----------------------------|--------------------------------------------------------------------------------|
| /usr/samples/snmpd/smi.my   | Defines the ASN.1 definitions by which the SMI is defined as in RFC 1155.      |
| /usr/samples/snmpd/mibII.my | Defines the ASN.1 definitions for the MIB II variables as defined in RFC 1213. |

## named.conf File Format for TCP/IP

### Purpose

Defines the configuration and behavior of the **named** daemon.

### Description

The **/etc/named.conf** file is the default configuration file for the **named8** and **named9** server. If the **named** daemon is started without specifying an alternate file, the **named** daemon reads this file for information on how to set up the local name server.

The format of the **named.conf** file is different depending on which version of the **named** server is configured. The file format information for both **named8** and **named9** can be found below.

**Note:** The **named** daemon reads the configuration file only when the **named** daemon starts, or when the **named** daemon receives an SRC **refresh** command or a **SIGHUP** signal.

The data in the **named.conf** file specifies general configuration characteristics for the name server, defines each zone for which the name server is responsible (its zones of authority), and provides further config information per zone, possibly including the source DOMAIN database file for the zone.

Any database files referenced in the **named.conf** file must be in the Standard Resource Record Format. These data files can have any name and any directory path. However, for convenience in maintaining the **named** database, they are given names in the following form: **/etc/named.extension**. The general format of **named** data files is described in DOMAIN Data File, DOMAIN Reverse Data File, DOMAIN Cache File, and DOMAIN Local File.

### Format of the named.conf file when configuring named8

#### General

Comments in the **named.conf** file can begin with a # (pound sign) or // (two forward slashes), or can be enclosed in the C-style comment characters, for example, /\* comment text \*/.

Configuration options are lines of text beginning with a keyword, possibly including some option text or a list, and ending in a ; (semicolon).

The **named.conf** file is organized into stanzas. Each stanza is an enclosed set of configuration options that define either general characteristics of the daemon or a zone configuration. Certain stanza definitions are allowed only at the top level, therefore nesting these stanzas is not allowed. The current top-level configuration stanza keywords are: acl, key, logging, options, server, and zone.

Further configuration information can be incorporated through the **include** keyword into the **conf** file. This keyword directs the daemon to insert the contents of the indicated file into the current position of the **include** directive.

### Access Control List (ACL) Definition

```
acl acl-name {
 access-element;
 [access-element; ...]
};
```

Defines an access control list to be referenced throughout the configuration file by *acl-name*. Multiple acl definitions can exist within one configuration file if each *acl-name* is unique. Additionally, four default access control lists are defined:

- **any** Any host is allowed.
- **none** No host is allowed.
- **localhost** Only the localhost is allowed.
- **localnets** Only hosts on a network matching a name server interface is allowed.

| Option                | Values                             | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-element</i> | IP-address IP-prefix acl-reference | <p>Defines a source as allowed or disallowed. Multiple <i>access-elements</i> are allowed inside the acl stanza.</p> <p>Each element can be an IP address in dot notation (for example, 9.3.149.66) an IP prefix in CIDR or slash notation (for example, 9.3.149/24) or a reference to another access control list (for example, <b>localhost</b>).</p> <p>Additionally, each element indicates whether the element is allowed or disallowed access through an ! (exclamation point) modifier prepended to the element.</p> <p>For example:</p> <pre>acl hostlist1 {     !9.53.150.239;     9.3.149/24; };</pre> <p>When the access control list “hostlist1” is referenced in the configuration, it implies to allow access from any host whose IP address begins with 9.3.149 and to disallow access from the internet host 9.53.150.239.</p> |

### Key Definition

```
key key-name {
 algorithm alg-id;
 secret secret-string;
};
```

Defines an algorithm and shared secret key to be referenced in a server stanza and used for authentication by that name server. This feature is included for future use and is currently unused in the name server.

| Option    | Values                      | Explanation                                                                                                                                  |
|-----------|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| algorithm | <i>alg-id</i> string        | A quoted-string that defines the type of security algorithm that is used when interpreting the secret string. None are defined at this time. |
| secret    | <i>secret-string</i> string | A quoted-string that is used by the algorithm to authenticate the host.                                                                      |

## Logging Configuration

```
logging {
```

```
[channel channel-name {
 file file-name
 [versions (num-vers | unlimited)]
 [size size-value]
 | syslog (kern | user | mail | daemon |
 syslog | lpr | news | uucp)
 | null);
 [print-category (yes | no);]
 [print-severity (yes | no);]
 [print-time (yes | no);]
}; ...]
[category category-name {
 channel-reference;
 [channel-reference; ...]
}; ...]
};
```

In this newest version of the name server, the logging facility has been greatly improved to allow for much reconfiguration of the default logging mechanism. The **logging** stanza is used to define logging output channels and to associate the predefined logging categories with either the predefined or user-defined logging output channels.

When no logging stanza is included in the conf file, the name server still logs messages and errors just as it has in previous releases. Informational and some critical messages are logged through the syslog daemon facility, and debug and other esoteric information are logged to the **named.run** file when the global debug level (set with the -d command-line option) is non-zero.

| Option   | Values                        | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| channel  |                               | <p>Defines an output channel to be referenced later by the <i>channel-name</i> identifier. An output channel specifies a destination for output messages to be sent as well as some formatting information to be used when writing the output message. More than one output channel can be defined if each <i>channel-identifier</i> is unique. Also, each output channel can be referenced from multiple logging categories.</p> <p>There are four predefined output channels:</p> <ul style="list-style-type: none"> <li>• <b>default_syslog</b> sends “info” and higher severity messages to syslog’s “daemon” facility</li> <li>• <b>default_debug</b> writes debug messages to the <code>named.run</code> file as specified by the global debug level</li> <li>• <b>default_stderr</b> writes “info” and higher severity messages to stderr</li> <li>• <b>null</b> discards all messages</li> </ul> |
| file     | <i>file-name</i> string       | <p>Defines an output channel as one that logs messages to an output file. The file used for output is specified with the <i>file-name</i> string. Additionally, the <b>file</b> option allows controlling the number of versions of the output file that should be kept, and the size limit that the output file should not exceed.</p> <p>The <b>file</b>, <b>syslog</b>, and <b>null</b> output paths are mutually exclusive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| versions | <i>num-versions</i> unlimited | <p>Specifies the number of old output files that should be kept. When an output file is reopened, rather than replacing a possible existing output file, the existing output file is saved as an old output file with a <i>.value</i> extension. Using the <i>num-versions</i> value, one can limit the number of old output files to be kept. However, specifying the <b>unlimited</b> keyword indicates to continually accumulate old output file versions. By default, no old versions of any log file are kept.</p>                                                                                                                                                                                                                                                                                                                                                                                  |
| size     | <i>size-value</i>             | <p>Specifies the maximum size of the log file used by this channel. By default, the size is unlimited. However, when a size is configured, once <i>size-value</i> bytes are written to the file, nothing more is written until the file is reopened.</p> <p>Accepted values for <i>size-value</i> include the word “unlimited” and numbers with k, m, or g modifiers specifying kilobytes, megabytes, and gigabytes respectively. For example, 1000k and 1m indicate one thousand kilobytes and one megabyte respectively.</p>                                                                                                                                                                                                                                                                                                                                                                           |

| Option   | Values                                                            | Explanation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| syslog   | kern user mail daemon auth syslog lpr news uucp                   | <p>Defines an output channel as one that redirects its messages to the syslog service. The supported value keywords correspond to facilities logged by the syslog service.</p> <p>Ultimately, the syslog service defines which received messages are logged through the service, therefore, if defining a channel to redirect its messages to the syslog service's user facility would not result in any visibly logged messages if the syslog service is not configured to output messages from this facility.</p> <p>For more information concerning the syslog service, see the <b>syslogd</b> daemon.</p> <p>The <b>file</b>, <b>syslog</b>, and <b>null</b> output paths are mutually exclusive.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| null     |                                                                   | <p>Defines an output channel through which all messages are discarded. All other output channel options are invalid for an output channel whose output path is null.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| severity | critical error warning notice info debug [ <i>level</i> ] dynamic | <p>Sets a threshold of message severities to be logged through the output channel. While these severity definitions are like those used by the syslog service, for the name server they also control output through file path channels. Messages must meet or exceed the severity level to be logged through the output channel. The <b>dynamic</b> severity specifies that the name server's global debug level (specified when the daemon is invoked with the <b>-d</b> flag) controls which messages pass through the output channel.</p> <p>Also, the <b>debug</b> severity can specify a <i>level</i> modifier which is an upper threshold for debug messages whenever the name server has debugging enabled at any level. A lower debug level indicates less information is to be logged through the channel. It is not necessary for the global debug level to meet or exceed the debug <i>level</i> value.</p> <p>If used with the <b>syslog</b> output path, the syslog facility ultimately controls what severities are logged through the syslog service. For example, if the syslog service is configured to only log <b>daemon.info</b> messages, and the name server is configured to channel all debug messages to the syslog service, the syslog service filters the messages from its output path.</p> |

| <i>category-name</i>                     | default config parser queries lame-servers statistics panic update ncache xfer-in xfer-out db event-lib packet notify cname security os insist maintenance load response-checks | <p>The <i>category-name</i> specifies which logging category is to be associated with the listed <i>channel-references</i>. This results in any output text generated by the name server daemon for that logging category to be redirected through each of the <i>channel-references</i> listed.</p> <p>The default category defines all messages that are not listed in one of the specific categories listed. Also, the insist and panic categories are associated with messages that define a fatal inconsistency in the name server's state. The remaining categories define messages that are generated when handling specific functions of the name server. For example, the update category is used when logging errors or messages specific to the handling of a dynamic zone update, and the parser category is used when logging errors or messages during the parsing of the conf file.</p> |

| Option                   | Values | Explanation                                                                                                                                                                                                                                            |
|--------------------------|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>channel-reference</i> |        | References a <i>channel-name</i> identifier defined previously in the <b>logging</b> configuration stanza. Therefore, every message associated with the defined <i>category-name</i> is logged through each of the defined <i>channel-references</i> . |

## Global Options

```
options {
 [directory path-string;]
 [named-xfer path-string;]
 [dump-file path-string;]
 [pid-file path-string;]
 [statistics-file path-string;]
 [auth-nxdomain (yes | no);]
 [fake-iquery (yes | no);]
 [fetch-glue (yes | no);]
 [multiple-cnames (yes | no);]
 [notify (yes | no);]
 [recursion (yes | no);]
 [forward (only | first);]
 [forwarders { ipaddr; [...] };]
 [check-names
 (master|slave|response)
 (warn|fail|ignore);]
 [allow-query { access-element; [...] };]
 [allow-transfer { access-element; [...] };]
 [listen-on [port port-num] { access-element; [...] }; ...]
 [query-source [address (ipaddr|*)] [port (port|*)];]
 [max-transfer-time-in seconds;]
 [transfer-format (one-answer | many-answers);]
 [transfers-in value;]
 [transfers-out value;]
 [transfers-per-ns value;]
 [coresize size-value;]
 [datasize size-value;]
 [files size-value;]
 [stacksize size-value;]
 [clean-interval value;]
 [interface-interval value;]
 [statistics-interval value;]
 [topology { access-element; [...] };]
};
```

Defines many globally available options to modify basic characteristics of the name server.

Because some of the options in this configuration stanza may modify the behavior in how the **named** daemon reads and interprets later sections of the named file, it is highly recommended that the **options** stanza be the first stanza listed in the configuration file.

| Option           | Values             | Default |
|------------------|--------------------|---------|
| <b>directory</b> | <i>path-string</i> | "."     |

Indicates the directory from which all relative paths are anchored. The *path-string* parameter must be a quoted string. For example, to indicate that all zone files exist in the "/usr/local/named/data" without listing each file in the zone definitions, specify the global option directory as: options { directory "/usr/local/named/data"; };

| Option                                                                                                                                                                                                                                                                                                                                                                          | Values             | Default                  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|--------------------------|
| <b>named-xfer</b><br>Specifies the path and executable name of the <b>named-xfer</b> command used for inbound zone transfers. The <i>path-string</i> parameter must be a quoted string.                                                                                                                                                                                         | <i>path-string</i> | "/usr/sbin/named-xfer"   |
| <b>dump-file</b><br>Specifies a filename to which the database in the memory is dumped whenever the <b>named</b> daemon receives a SIGINT signal.                                                                                                                                                                                                                               | <i>path-string</i> | "/usr/tmp/named_dump.db" |
| <b>pid-file</b> Specifies the file in which the <b>named</b> daemon writes its PID value.                                                                                                                                                                                                                                                                                       | <i>path-string</i> | "/etc/named.pid"         |
| <b>statistics-file</b><br>Specifies the file to which the name server appends operating statistics when it receives the SIGILL signal.                                                                                                                                                                                                                                          | <i>path-string</i> | "/usr/tmp/named.stats"   |
| <b>auth-nxdomain</b><br>Controls whether the server should respond authoritatively when returning an NXDOMAIN response.                                                                                                                                                                                                                                                         | yes no             | yes                      |
| <b>fake-iquery</b><br>Controls whether the server should respond to obsolete IQUERY requests.                                                                                                                                                                                                                                                                                   | yes no             | no                       |
| <b>fetch-glue</b><br>Controls whether the server should search for "glue" records to include in the additional section of a query response.                                                                                                                                                                                                                                     | yes no             | yes                      |
| <b>multiple-cnames</b><br>Controls whether the server will allow multiple CNAME records for one domain name in any of its zone databases. This practice is discouraged but an option remains for backwards compatibility.                                                                                                                                                       | yes no             | no                       |
| <b>notify</b> Controls whether the name server will send NOTIFY messages to its slave servers upon realization of zone changes. Because the slave servers almost immediately respond to the NOTIFY message with a request for zone transfer, this limits the amount of time that the databases are out of synchronization in the master and slave relationship.                 | yes no             | yes                      |
| <b>recursion</b><br>Controls whether the server will attempt to resolve names outside of its domains on behalf of the client. If set to no, the name server returns a referral to the client in order for the client to continue searching for the name. Used with the fetch-glue option, one can contain the amount of data that grows in the memory cache of the name server. | yes no             | yes                      |
| <b>forward</b> Controls how forwarding is used when forwarding is enabled. When set to first, the name server attempts to search for a name whenever the forwarded host does not provide an answer. However, when set to only, the name server does not attempt this extra work.                                                                                                | only first         | first                    |

| Option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Values                                                                                                                        | Default                                   |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| <b>forwarders</b><br><br>Enables the use of query forwarding when defining a Forwarding Name Server. The <i>ipaddr</i> parameter list specifies the hosts to which the query should be forwarded when it cannot be resolved from the local database. Each <i>ipaddr</i> is an internet address in standard dot notation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | <i>ipaddr</i>                                                                                                                 | (empty list)                              |
| <b>check-names</b><br><br>Controls how the name server handles non-RFC compliant host names and domain names through each of its operation domains.<br><br>The <b>master</b> keyword specifies how to handle malformed names in a master zone file. The <b>slave</b> keyword specifies how to handle malformed names received from a master server. The <b>response</b> keyword specifies how to handle malformed names received in response to a query.<br><br><b>ignore</b> directs the server to ignore any malformed names and continue normal processing. <b>warn</b> directs the server to warn the administrator through logging, but to continue normal processing. <b>fail</b> directs the server to reject the name entirely. For the responses to queries, this implies that the server will return a REFUSED message to the original query host. | master ignore master warn<br>master fail slave ignore slave<br>warn slave fail response ignore<br>response warn response fail | master fail slave warn<br>response ignore |

| Item                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Description                                                              |                                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|-------------------------------------|
| <b>allow-query</b><br><br>Limits the range of querying hosts allowed to access the system. Each <i>access-element</i> is specified in the same manner as in the acl stanza defined earlier.                                                                                                                                                                                                                                                                                                                                                                                            | <i>access-element</i>                                                    | any                                 |
| <b>allow-transfer</b><br><br>Limits the range of querying hosts that are requesting zone transfers. Each <i>access-element</i> is specified in the same manner as in the acl stanza defined earlier.                                                                                                                                                                                                                                                                                                                                                                                   | <i>access-element</i>                                                    | any                                 |
| <b>listen-on</b><br><br>Limits the interfaces available to the name server daemon and controls which port to use to listen for queries. By default, the name server uses all interfaces on the system and listens on port 53. Additionally, multiple <b>listen-on</b> definitions are allowed within the <b>options</b> stanza.<br><br>Each access element is specified in the same manner as in the acl stanza defined earlier. The following example limits the name server to using only the interface with address 9.53.150.239: <code>listen-on port 53 { 9.53.150.239; };</code> | <code>port <i>port-num</i> <i>access-element</i></code>                  | <code>port 53 { localhost; }</code> |
| <b>query-source</b><br><br>Modifies the default address and port from which queries will originate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <code>address <i>ipaddr</i> address * port<br/>port <i>port</i> *</code> | <code>address * port *</code>       |

| Item                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Description             |              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|--------------|
| <b>max-transfer-time-in</b><br><br>Specifies the maximum amount of time an inbound zone transfer is allowed to run before it is aborted. This is used to control an event in which a child process of the name server does not execute or terminate properly.                                                                                                                                                                                                                         | <i>seconds</i>          | 120          |
| <b>transfer-format</b><br><br>Controls the method in which full zone transfers are sent to requestors. The one-answer method uses one packet per zone resource record while many-answers inserts as many resource records into one packet as possible. While the many-answers method is more efficient, it is only understood by the newest revisions of the name server. This option can be overridden in the <b>server</b> stanza to specify the method on a per name server basis. | one-answer many-answers | many-answers |
| <b>transfers-in</b><br><br>Specifies the maximum number of concurrent inbound zone transfers. While this limits the amount of time each slave zone is out of synchronization with the master's database, because each inbound transfer runs in a separate child process, increasing the <i>value</i> may also increase the load on the slave server.                                                                                                                                  | <i>value</i>            | 10           |
| <b>transfers-out</b><br><br>Specifies the maximum number of concurrent outbound zone transfers for the name server. This option is currently unused in the server, but will be available at a later time.                                                                                                                                                                                                                                                                             | <i>value</i>            | N/A          |
| <b>transfers-per-ns</b><br><br>Specifies the maximum amount of concurrent zone transfers from a specific remote name server. While this limits the amount of time each slave zone is out of synchronization with the master's database, increasing this value may increase the load on the remote master server.                                                                                                                                                                      | <i>value</i>            | 2            |
| <b>coresize</b><br><br>Configures some process-specific values for the daemon.<br><br>The default values or those inherited by the system and by the system's resources.<br><br>Each <i>size-value</i> can be specified as a number or as a number followed by the k, m, and g modifiers indicating kilobytes, megabytes, and gigabytes respectively.                                                                                                                                 | <i>size-value</i>       | default      |

| <b>cleandb-time</b><br>Specifies a time of day in which the database is scanned and any dynamic records whose set of SIG resource records are all expired are removed. For a dynamic zone which has <b>update-security</b> set to <b>presecured</b> , only the expired SIG KEY remains.<br><br>The default is to never perform this scan. Instead, the expired records remain until the name is queried.<br><br><i>time</i> is specified as HH:MM in a 24-hour format.                                                                                                                                                                | <i>time</i>           | N/A                   |
| <b>topology</b><br>Specifies a search order to use to find a preference in a list of addresses corresponding to a name server. Whenever a query is forwarded or a query must be made to another name server, it may be necessary to choose an address from a list of available addresses.<br><br>Each <i>access-element</i> , while seemingly similar to those specified in an <b>acl</b> stanza, is interpreted by its position in the list. The first elements in the list are preferred more than those following them. Negated elements (those specified with the ! (exclamation point) modifier) are considered least desirable. | <i>access-element</i> | localhost; localnets; |

## Server Specific Options

```
server ipaddr
{
 [bogus (yes | no);]
 [transfers value;]
}
[transfer-format (one-answer |
many-answers);]
```

Modifies the behavior in which the remote name server matching the specified *ipaddr* IP address should be treated.
