|-----------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bogus           | yes no                  | Indicates that the name server identified by the stanza should not be used again. The default value is no.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| transfers       | value                   | Overrides the globally available option <b>transfers-per-ns</b> . Specifies a maximum value for the number of concurrent inbound zone transfers from the foreign name server identified by the stanza.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| transfer-format | one-answer many-answers | Overrides the globally available option <b>transfer-format</b> to a specific value for the specified server. The <b>transfer-format</b> option indicates to the name server how to form its outbound full zone transfers. By default, the value is inherited from the options stanza (where it defaults to <b>many-answers</b> ). <b>one-answer</b> specifies that only one resource record can be sent per packet during the zone transfer, whereas <b>many-answers</b> indicates to entirely fill the outbound packet with resource records. The <b>many-answers</b> format is only available in the newest revisions of the name server. |

## Zone Definition

```

zone domain-string [class] {
 type (hint | stub | slave | master);
 [file path-string;]
 [masters { ipaddr; [...] };]
 [check-names (warn | fail | ignore);]
 [allow-update { access-element; [...] };]
 [update-security (unsecured | presecured | controlled);]
 [allow-query { access-element; [...] };]
 [allow-transfer { access-element; [...] };]
 [max-transfer-time-in seconds;]
 [notify (yes | no);]
 [also-notify { ipaddr; [...] };]
 [dont-notify { ipaddr; [...] };]
 [notify-delaytime seconds;]
 [notify-retrytime seconds;]
 [notify-retrycount value;]
 [dump-interval seconds;]
 [incr-interval seconds;]
 [deferupdcnt value;]
 [key-xfer (yes | no);]
 [timesync (yes | no);]
 [timesync-xfer (yes | no);]
 [save-backups (yes | no);]
 [ixfr-directory path-string;]
 [separate-dynamic (yes | no);]
};
```

The zone stanza is used to define a zone, its type, possible location of data, and operating parameters. The *domain-string* is a quoted string specifying the zone, where “.” is used to specify the root zone. The *class* parameter specifies the *class* of the zone as either in, hs, hesiod, or chaos. By default, the *class* is assumed to be IN.

| Option and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Values                 | Default |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|---------|
| <b>type</b> Defines the type of the zone. <code>hint</code> zones, previously regarded as cache zones, only describe a source for information not contained in the other defined zones. A <code>stub</code> zone is one similar to a <code>slave</code> zone. While the <code>slave</code> zone replicates the entire database of its master, the <code>stub</code> zone only replicates the NS resource records. The <code>master</code> zone maintains a database on disk.                                                                         | hint stub slave master | N/A     |
| Based upon the selection of zone type, some of the other options are required while others may be impertinent. Zones of type <code>hint</code> and <code>master</code> require the <code>file</code> option, while zones of type <code>slave</code> and <code>stub</code> require the <code>masters</code> option. Additionally, the only other option available to a <code>hint</code> zone is the <code>check-names</code> option.                                                                                                                 |                        |         |
| <b>file</b> Specifies the location for the source of data specific to the zone. This parameter is only optional for <code>stub</code> and <code>slave</code> zones, where its inclusion indicates that a locally saved copy of the remote zone can be kept. The <i>path-string</i> parameter is a quoted string which can specify the file name either non-relative or relative to the options stanza's directory. If the path is intended to be specified relative to the server root, the options stanza must be specified before the zone stanza. | <i>path-string</i>     | N/A     |
| <b>masters</b> Specifies a list of sources that are referenced for a <code>slave</code> or <code>stub</code> zone to retrieve its data. This option is not valid for any other type of zone, and must be included for either of these two types.                                                                                                                                                                                                                                                                                                     | <i>ipaddr</i>          | N/A     |
| <b>check-names</b><br>Overrides the <code>check-names</code> option in the global options stanza. The default value is inherited from the options stanza, where its default is <code>fail</code> for master zones and <code>warn</code> for slave zones.                                                                                                                                                                                                                                                                                             | warn fail ignore       |         |
| <b>allow-update</b><br>Indicates from what source addresses a zone accepts dynamic updates. <i>access-elements</i> are specified in the same manner as they are for the <code>acl</code> stanza. Because of the inherent insecurity of a dynamic update, this value defaults to <code>none</code> . If no <code>update-security</code> is specified, dynamic updates should be limited to a specific set of secured machines.                                                                                                                        | <i>access-element</i>  | none    |

| Option and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Values                                | Default   |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-----------|
| <b>update-security</b><br><br>Valid only when the <code>allow-update</code> option specifies at least one source address, <code>update-security</code> defines what type of secured update mechanism the zone uses. The current zone update security method is a non-standard two-key method, but is compatible with previous releases of the name server.<br><br><code>presecured</code> indicates that a zone only accepts updates for which names and resource records exist, unless the update is signed by the authorizing key of the zone. Normally, this means that the zone must be prepopulated with the names and records it is to maintain. <code>controlled</code> specifies a zone in which names can be added to the database without the signature of the zone's authorizing key, but existing records cannot be modified without being signed by the <code>KEY</code> resource record's corresponding private key.<br><br>Note that a proper <code>presecured</code> or <code>controlled</code> zone must contain a zone <code>KEY</code> resource record.<br><br>See the TCP/IP name resolution for more information regarding zone update security. | unsecured<br>presecured<br>controlled | unsecured |
| <b>allow-query</b><br><br>Overrides the globally available option <code>allow-query</code> . This option's default is inherited from the global options stanza, where its default is <code>any</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | <i>access-element</i>                 | NA        |
| <b>allow-transfer</b><br><br>Overrides the globally available option <code>allow-transfer</code> . This option's default is inherited from the global options stanza, where its default is <code>any</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | <i>access-element</i>                 | NA        |
| <b>max-transfer-time-in</b><br><br>Overrides the globally available option <code>max-transfer-time-in</code> . This option's default is inherited from the global options stanza, where its default is <code>120</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <i>seconds</i>                        |           |
| <b>notify</b><br><br>Overrides the globally available option <code>notify</code> . This option's default is inherited from the global options stanza, where its default is <code>yes</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | yes<br>no                             |           |
| <b>also-notify</b><br><br>The default NOTIFY mechanism notifies slave servers of a change in the DOMAIN database in order to limit the amount of time that the slave server retains a zone out of synchronization with the master server. The <code>also-notify</code> option allows for the addition of addresses to submit the notifications.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <i>ipaddr</i>                         | N/A       |
| <b>dont-notify</b><br><br>Specifies a list of IP addresses to be removed from the default list of NOTIFY recipients. This option is useful if a name server is known to be problematic when receiving NOTIFY requests.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <i>ipaddr</i>                         | N/A       |

| Option and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Values         | Default |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|---------|
| <b>notify-delaytime</b><br>Specifies an estimated time of delay between notifications to multiple name servers. Because the receipt of a NOTIFY message usually triggers the prompt request for a zone transfer, this option can tune to latency in which each server responds with the request for the modified zone.<br><br>The real value used is randomized between the specified number of <i>seconds</i> and twice this value.                                                                                                                                                                                 | <i>seconds</i> | 30      |
| <b>notify-retrytime</b><br>Specifies the number of <i>seconds</i> in which the name server waits to retransmit a NOTIFY message which has gone unresponded.                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <i>seconds</i> | 60      |
| <b>notify-retrycount</b><br>Specifies the maximum number of tries that the name server attempts to send unanswered NOTIFY messages to other name servers.                                                                                                                                                                                                                                                                                                                                                                                                                                                            | <i>value</i>   | 3       |
| <b>dump-interval</b><br>Specifies an interval in which the name server rewrites a dynamic zone to the zone file. In the interim, all updates and other transactions are logged in the transaction log file for performance reasons. Aside from this periodic zone dump, the transaction log file is only discarded and the zone is only dumped when the name server is properly shut down.<br><br>This option is only valid for zones in which the allow-update option specifies at least one valid accessor.<br><b>Note:</b> The transaction log file name is the zone file name with an appended ".log" extension. | <i>seconds</i> | 3600    |
| <b>incr-interval</b><br>Specifies an interval in which the name server accepts dynamic updates while not increasing the zone's SOA record's serial level. Because a change in the zone SOA record instantiates a NOTIFY message, limiting this occurrence limits the amount of zone transfer requests at the expense of minimal zone differences between a dynamic master server and its slave.<br><br>This option is only valid for zones in which the allow-update option specifies at least one valid accessor.                                                                                                   | <i>seconds</i> | 300     |
| <b>deferupdcnt</b><br>Specifies a threshold value for the number of properly applied updates received during one incr-interval interval. If more than <i>value</i> updates are realized during the interval, the name server modifies the zone SOA serial level and later will NOTIFY each of the slave servers. Use this value to limit the database replication inconsistencies in an environment where dynamic zone updates occur infrequently but in large magnitude.<br><br>This option is only valid for zones in which the allow-update option specifies at least one valid accessor.                         | <i>value</i>   | 100     |
| <b>key-xfer</b> Specifies whether the server should transmit KEY resource records during a zone transfer. In a very controlled environment where KEY queries are only made to the master name server, setting this option to no saves the zone transfer time and improves performance.                                                                                                                                                                                                                                                                                                                               | yes no         | yes     |

| Option and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Values             | Default |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|---------|
| <b>timesync</b><br>Specifies that a name server should calculate the true expiration time of a SIG resource record using its own clock rather than relying on the expiration time set by a possible update source. This removes the inconsistencies involved when dynamic zone updaters have their system clocks misaligned from the name server host. Because enabling this option modifies the output and interpretation of a SIG resource record in a DOMAIN database file, disabling this option may be required when manually transferring a DOMAIN database file to another name server.                                                                                                                                                                                                                                                                                                                                       | yes no             | yes     |
| <b>timesync-xfer</b><br>Specifies which SIG resource record expiration time is transferred during a zone transfer. Enabling this option is only valid when the timesync option is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | yes no             | yes     |
| <b>ixfr-directory</b><br>Specifies a directory in which temporary data files are contained for use with this zone. The datafiles contain incremental zone changes and are essential to the proper use of the Incremental Zone Transfer (IXFR) method. Because these files are created and destroyed dynamically by the name server, one should not specify a globally-writable directory. Additionally, the directory specified must be unique from other ixfr-directory options specified in other zones.<br><br>The default value for this directory is derived from the zone's file name or domain name. By default, a directory is created in an "ixfrdata" directory within the name server's default directory. Contained in this directory will be subdirectory matching the base name of the zone's file name or domain name.<br><br>It is not necessary to specify this option for the proper behavior of the IXFR feature. | <i>path-string</i> |         |
| <b>save-backups</b><br>To properly calculate an incremental zone difference between server invocations, it is necessary to determine the zone database differences prior to the shutdown of the server and after the loading of the server. By enabling this option, a backup of the zone file is written and read upon loading of the name server to determine any zone differences.<br><br>While enabling this option is necessary to use the IXFR transfer method after a stop and restart transition of the name server, it is not necessary to realize incremental zone differences when a zone file is modified and signalled to reload through the SRC refresh command or SIGHUP signal.                                                                                                                                                                                                                                      | yes no             | no      |

| Option and Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Values | Default |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|---------|
| <b>separate-dynamic</b><br>Instructs the name server to retain \$INCLUDE references in a dynamic zone when the DOMAIN database file is written to disk. The behavior of this feature implies that resource records that can be modified through the dynamic update mechanism exist in the DOMAIN database file referenced by the file option, while other resource records that should not be modified through the dynamic update mechanism be contained in files included (through the \$INCLUDE directive) by the DOMAIN database file. | yes no | no      |

## Examples

The following examples show some of the various methods to use to configure a simple **named.conf** file. In these examples, two networks are represented: abc and xyz.

Network abc consists of:

- gobi.abc, the master name server for the abc network, 192.9.201.2
- mojave.abc, a host machine, 192.9.201.6
- sandy.abc, a slave name server for the abc network and the gateway between abc and xyz, 192.9.201.3

Network xyz consists of:

- kalahari.xyz, master name server for the xyz network, 160.9.201.4
- lopnor.xyz, a host machine, 160.9.201.5
- sahara.xyz, a host machine and hint name server for the xyz network, 160.9.201.13
- sandy.xyz, a slave name server for the xyz network and gateway between abc and xyz, 160.9.201.3

**Note:** sandy, a gateway host, is on both networks and also serves as a slave name server for both domains.

1. The **/etc/named.conf** file for gobi.abc, the master name server for network abc, contains these entries:
 

```
conf file for abc master server - gobi.abc # server 192.9.201.3 { transfer-format many-answers; };
zone "abc" in { type master; file "/etc/named.abcdatal"; allow-update { localhost; }; };
zone "201.9.192.in-addr.arpa" in { type master; file "/etc/named.abcrev"; allow-update { localhost; }; };
zone "0.0.127.in-addr.arpa" in { type master; file "/etc/named.abclocal"; };
```
2. The **/etc/named.conf** file for kalahari.xyz, the master name server for network xyz, contains these entries:
 

```
conf file for abc master server - kalahari.xyz # acl xyz-slaves { 160.9.201.3; };
options { directory "/etc"; allow-transfer { xyz-slaves; localhost; }; };
zone "xyz" in { type master; file "named.xyzdata"; };
zone "9.160.in-addr.arpa" in { type master; file "named.xyrev"; };
zone "0.0.127.in-addr.arpa" in { type master; file "named.xyzlocal"; };
```
3. The **/etc/named.conf** file for sandy, the slave name server for networks abc and xyz, contains the following entries:
 

```
conf file for slave server for abc and xyz - sandy # options { directory "/etc"; };
zone "abc" in { type slave; masters { 192.9.201.2; }; file "named.abcdatal.bak"; };
zone "xyz" in { type slave; masters { 160.9.201.4; }; file "named.xyzdata.bak"; };
zone "201.9.192.in-addr.arpa" in { type slave; masters { 192.9.201.2; }; };
zone "9.160.in-addr.arpa" in { type slave; masters { 192.9.201.4; }; };
```

- zone "0.0.127.in-addr.arpa" in { type master; file "named.local"; };
4. The **/etc/named.conf** file for sahara, a hint name server for the network xyz, contains the following entries:
 

```
conf file for hint server for xyz - sahara # zone "." in { type hint; file "/etc/named.ca"; };
zone "0.0.127.in-addr.arpa" in { type master; file "/etc/named.local"; };
```

## **Format of the named.conf file when configuring named9**

### **General**

A BIND 9 configuration consists of statements and comments. Statements end with a semicolon. Statements and comments are the only elements that can appear without enclosing braces. Many statements contain a block of substatements, which are also terminated with a semicolon.

The following statements are supported:

| Item                | Description                                                                          |
|---------------------|--------------------------------------------------------------------------------------|
| <b>acl</b>          | Defines a named IP address matching list, for access control and other uses.         |
| <b>controls</b>     | Declares control channels to be used by the rndc utility.                            |
| <b>include</b>      | Includes a file.                                                                     |
| <b>key</b>          | Specifies key information for use in authentication and authorization using TSIG.    |
| <b>logging</b>      | Specifies what the server logs, and where the log messages are sent.                 |
| <b>options</b>      | Controls global server configuration options and sets defaults for other statements. |
| <b>server</b>       | Sets certain configuration options on a per-server basis.                            |
| <b>trusted-keys</b> | Defines trusted DNSSEC keys.                                                         |
| <b>view</b>         | Defines a view.                                                                      |
| <b>zone</b>         | Defines a zone.                                                                      |

The **logging** and **options** statements may only occur once per configuration.

### **acl Statement Grammar**

```
acl acl-name {
 address_match_list
};
```

### **acl Statement Definition and Usage**

The **acl** statement assigns a symbolic name to an address match list. It gets its name from a primary use of address match lists: Access Control Lists (ACLs).

Note that an address match list's name must be defined with **acl** before it can be used elsewhere; no forward references are allowed.

The following ACLs are built-in:

| Item      | Description                                                                |
|-----------|----------------------------------------------------------------------------|
| any       | Matches all hosts.                                                         |
| none      | Matches no hosts.                                                          |
| localhost | Matches the IPv4 addresses of all network interfaces on the system.        |
| localnets | Matches any host on an IPv4 network for which the system has an interface. |

The **localhost** and **localnets** ACLs do not currently support IPv6 (that is, **localhost** does not match the host's IPv6 addresses, and localnets does not match the host's attached IPv6 networks) due to the lack of a standard method of determining the complete set of local IPv6 addresses for a host.

### controls Statement Grammar

```
controls {
 inet (ip_addr | *) [port ip_port] allow { address_match_list }
 keys { key_list };
 [inet ...;]
};
```

### controls Statement Definition and Usage

The **controls** statement declares control channels to be used by system administrators to affect the operation of the local nameserver. These control channels are used by the **rndc** utility to send commands to and retrieve non-DNS results from a nameserver.

An **inet** control channel is a TCP/IP socket accessible to the Internet, created at the specified **ip\_port** on the specified **ip\_addr**. If no port is specified, port 953 is used by default. "\*" cannot be used for **ip\_port**.

The ability to issue commands over the control channel is restricted by the **allow** and **keys** clauses. Connections to the control channel are permitted based on the address permissions in **address\_match\_list**. **key\_id** members of the **address\_match\_list** are ignored, and instead are interpreted independently based the **key\_list**. Each **key\_id** in the **key\_list** is allowed to be used to authenticate commands and responses given over the control channel by digitally signing each message between the server and a command client. All commands to the control channel must be signed by one of its specified keys to be honored.

If no controls statement is present, **named9** sets up a default control channel listening on the loopback address 127.0.0.1 and its IPv6 counterpart ::1. In this case, and also when the controls statement is present but does not have a **keys** clause, **named9** attempts to load the command channel key from the **/etc/rndc.key** file in (or whatever **sysconfdir** was specified as when BIND was built). To create a **rndc.key** file, run **rndc-confgen -a**.

The **rndc.key** feature was created to ease the transition of systems from BIND 8, which did not have digital signatures on its command channel messages and thus did not have a **keys** clause. It makes it possible to use an existing BIND 8 configuration file in BIND 9 unchanged, and still have **rndc** work the same way **rndc** worked in BIND 8, simply by executing the command **rndc-keygen -a** after BIND 9 is installed.

Since the **rndc.key** feature is only intended to allow the backward-compatible usage of BIND 8 configuration files, this feature does not have a high degree of configurability. You cannot easily change the key name or the size of the secret, so you should make a **rndc.conf** with your own key if you wish to change those things. The **rndc.key** file also has its permissions set such that only the owner of the file (the user that named is running as) can access it. If you desire greater flexibility in allowing other users to access **rndc** commands then you need to create an **rndc.conf** and make it group readable by a group that contains the users who should have access. The UNIX control channel type of BIND 8 is not supported in BIND 9. If it is present in the controls statement from a BIND 8 configuration file, it is ignored and a warning is logged.

## include Statement Grammar

```
include filename;
```

## include Statement Definition and Usage

The **include** statement inserts the specified file at the point that the **include** statement is encountered. The **include** statement facilitates the administration of configuration files by permitting the reading or writing of some things but not others. For example, the statement could include private keys that are readable only by a nameserver.

## key Statement Grammar

```
key key_id {
 algorithm string;
 secret string;
};
```

## key Statement Definition and Usage

The **key** statement defines a shared secret key for use with TSIG.

The **key** statement can occur at the top level of the configuration file or inside a view statement. Keys defined in top-level **key** statements can be used in all views. Keys intended for use in a controls statement must be defined at the top level.

The *key\_id*, also known as the key name, is a domain name uniquely identifying the key. It can be used in a "server" statement to cause requests sent to that server to be signed with this key, or in address match lists to verify that incoming requests have been signed with a key matching this name, algorithm, and secret. The *algorithm\_id* is a string that specifies a security/authentication algorithm. The only algorithm currently supported with TSIG authentication is **hmac-md5**. The *secret\_string* is the secret to be used by the algorithm, and is treated as a base-64 encoded string.

## logging Statement Grammar

```
logging {
 [channel channel_name {
 (file path name
 [versions (number | unlimited)]
 [size size spec]
 | syslog syslog_facility
 stderr
 null);
 [severity (critical | error | warning | notice |
 info | debug [level] | dynamic);]
 [print-category yes or no;]
 [print-severity yes or no;]
 [print-time yes or no;]
 };]
 [category category_name {
 channel_name ; [channel_name ; ...]
 };]
 ...
};
```

## logging Statement Definition and Usage

The **logging** statement configures a wide variety of logging options for the nameserver. Its **channel** phrase associates output methods, format options, and severity levels with a name that can then be used with the **category** phrase to select how various classes of messages are logged.

Only one **logging** statement is used to define as many channels and categories as are wanted. If there is no **logging** statement, the logging configuration will be:

```
logging {
 category "unmatched" { "null"; };
 category "default" { "default_syslog"; "default_debug"; };
};
```

In BIND 9, the logging configuration is only established when the entire configuration file has been parsed. In BIND 8, it was established as soon as the **logging** statement was parsed. When the server is starting up, all logging messages regarding syntax errors in the configuration file go to the default channels, or to standard error if the **-g** option was specified.

### The channel Phrase

All log output goes to one or more channels; you can make as many of them as you want.

Every channel definition must include a destination clause that says whether messages selected for the channel go to a file, to a particular **syslog** facility, to the standard error stream, or are discarded. It can optionally also limit the message severity level that is accepted by the channel (the default is info), and whether to include a named-generated time stamp, the category name and/or severity level (the default is not to include any).

The **null** destination clause causes all messages sent to the channel to be discarded; in that case, other options for the channel are meaningless.

The **file** destination clause directs the channel to a disk file. It can include limitations both on how large the file is allowed to become, and how many versions of the file are saved each time the file is opened.

If you use the **versions** log file option, then **named9** retains that many backup versions of the file by renaming them when opening. For example, if you choose to keep 3 old versions of the file **lamers.log**, then just before it is opened **lamers.log.1** is renamed to **lamers.log.2**, **lamers.log.0** is renamed to **lamers.log.1**, and **lamers.log** is renamed to **lamers.log.0**. You can say **versions unlimited**; to not limit the number of versions. If a size option is associated with the log file, then renaming is only done when the file being opened exceeds the indicated size. No backup versions are kept by default; any existing log file is simply appended.

The **size** option for files is used to limit log growth. If the file ever exceeds the size, then **named9** stops writing to the file unless it has a **versions** option associated with it. If backup versions are kept, the files are rolled as described above and a new one begun. If there is no **versions** option, no more data is written to the log until some out-of-band mechanism removes or truncates the log to less than the maximum size. The default behavior is not to limit the size of the file.

Example usage of the size and versions options:

```
channel "an_example_channel" {
 file "example.log" versions 3 size 20m;
 print-time yes;
 print-category yes;
};
```

The **syslog** destination clause directs the channel to the system log. Its argument is a **syslog** facility as described in the **syslog** man page. How **syslog** handles messages sent to this facility is described in the **syslog.conf** man page. If you have a system which uses a very old version of **syslog** that only uses two arguments to the **openlog()** function, then this clause is silently ignored. The severity clause works like **syslog**'s "priorities," except that they can also be used if you are writing straight to a file rather than using **syslog**. Messages which are not at least of the severity level given are not selected for the channel; messages of higher severity levels are accepted.

If you are using **syslog**, then the **syslog.conf** priorities also determine what eventually passes through. For example, defining a channel facility and severity as daemon and debug but only logging **daemon.warning** via **syslog.conf** causes messages of severity **info** and **notice** to be dropped. If the situation is reversed, with **named9** writing messages of only **warning** or higher, then **syslogd** prints all messages it received from the channel.

The **stderr** destination clause directs the channel to the server's standard error stream. This is intended for use when the server is running as a foreground process, for example when debugging a configuration.

The server can supply extensive debugging information when it is in debugging mode. If the server's global debug level is greater than zero, then debugging mode is active. The global debug level is set either by starting the **named9** server with the **-d** flag followed by a positive integer, or by running **rndc trace**. The global debug level can be set to zero, and debugging mode turned off, by running **rndc notrace**. All debugging messages in the server have a debug level, and higher debug levels give more detailed output. Channels that specify a specific debug severity, for example:

```
channel "specific_debug_level" {
 file "foo";
 severity debug 3;
};
```

gets debugging output of level 3 or less any time the server is in debugging mode, regardless of the global debugging level. Channels with **dynamic** severity use the server's global level to determine what messages to print.

If **print-time** has been turned on, then the date and time are logged. **print-time** may be specified for a **syslog** channel, but is usually pointless since **syslog** also prints the date and time. If **print-category** is requested, then the category of the message is logged as well. Finally, if **print-severity** is on, then the severity level of the message is logged. The **print-** options may be used in any combination, and are always printed in the following order: time, category, severity. Here is an example where all three **print-** options are on:

```
28-Feb-2000 15:05:32.863 general: notice: running
```

There are four predefined channels that are used for **named9**'s default logging as follows.

```
channel "default_syslog" {
 syslog daemon; // send to syslog's daemon
 severity info; // facility
 // only send priority info
 // and higher
};

channel "default_debug" {
 file "named.run"; // write to named.run in
 // the working directory
 // Note: stderr is used instead
 // of "named.run"
 // if the server is started
 // with the '-f' option.
 severity dynamic; // log at the server's
 // current debug level
};

channel "default_stderr" { // writes to stderr
 stderr;
 severity info; // only send priority info
 // and higher
};
```

```

channel "null" {
 null; // toss anything sent to
 // this channel
};

```

The **default\_debug** channel has the special property that it only produces output when the server's debug level is nonzero. It normally writes to a file **named9run** in the server's working directory.

For security reasons, when the **-u** command-line option is used, the **named9run** file is created only after **named9** has changed to the new UID, and any debug output generated while **named9** is starting up and still running as root is discarded. If you need to capture this output, you must run the server with the **-g** option and redirect standard error to a file.

Once a channel is defined, it cannot be redefined. Thus you cannot alter the built-in channels directly, but you can modify the default logging by pointing categories at channels you have defined.

### **The category Phrase**

There are many categories, so you can send the logs you want to see wherever you want, without seeing logs you do not want. If you do not specify a list of channels for a category, then log messages in that category are sent to the **default** category instead. If you do not specify a default category, the following "default default" is used:

```
category "default" { "default_syslog"; "default_debug"; };
```

As an example, if you want to log security events to a file, but you also want to keep the default logging behavior, specify the following:

```

channel "my_security_channel" {
 file "my_security_file";
 severity info;
};

category "security" {
 "my_security_channel";
 "default_syslog";
 "default_debug";
};

```

To discard all messages in a category, specify the null channel:

```
category "xfer-out" { "null"; };
category "notify" { "null"; };
```

Following are the available categories and brief descriptions of the types of log information they contain.

| <b>Item</b>     | <b>Description</b>                                                                                                      |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>default</b>  | The default category defines the logging options for those categories where no specific configuration has been defined. |
| <b>general</b>  | The catch-all. Many things still are not classified into categories, and they all end up here.                          |
| <b>database</b> | Messages relating to the databases used internally by the name server to store zone and cache data.                     |
| <b>security</b> | Approval and denial of requests.                                                                                        |
| <b>config</b>   | Configuration file parsing and processing.                                                                              |
| <b>resolver</b> | DNS resolution, such as the recursive lookups performed on behalf of clients by a caching name server.                  |
| <b>xfer-in</b>  | Zone transfers the server is receiving.                                                                                 |
| <b>xfer-out</b> | Zone transfers the server is sending.                                                                                   |
| <b>notify</b>   | The NOTIFY protocol.                                                                                                    |
| <b>client</b>   | Processing of client requests.                                                                                          |

| Item                | Description                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>unmatched</b>    | Messages that named was unable to determine the class of or for which there was no matching <b>view</b> . A one line summary is also logged to the <b>client</b> category. This category is best sent to a file or stderr, by default it is sent to the <b>null</b> channel. |
| <b>network</b>      | Network operations.                                                                                                                                                                                                                                                          |
| <b>update</b>       | Dynamic updates.                                                                                                                                                                                                                                                             |
| <b>queries</b>      | Queries. Using the category <b>queries</b> enables query logging.                                                                                                                                                                                                            |
| <b>dispatch</b>     | Dispatching of incoming packets to the server modules where they are to be processed.                                                                                                                                                                                        |
| <b>dnssec</b>       | DNSSEC and TSIG protocol processing.                                                                                                                                                                                                                                         |
| <b>lame-servers</b> | Lame servers. These are misconfigurations in remote servers, discovered by BIND 9 when trying to query those servers during resolution.                                                                                                                                      |

```

## **options Statement Definition and Usage**

The **options** statement sets up global options to be used by BIND. This statement may appear only once in a configuration file. If more than one occurrence is found, the first occurrence determines the actual options used, and a warning is generated. If there is no **options** statement, an options block with each option set to its default is used.

### **version**

The version the server should report through a query of name `version.bind` in class **CHAOS**.  
The default is the real version number of this server.

### **directory**

The working directory of the server. Any non-absolute pathnames in the configuration file are taken as relative to this directory. The default location for most server output files (for example, `named.run`) is this directory. If a directory is not specified, the working directory defaults to `"."` the directory from which the server was started. The directory specified should be an absolute path.

### **named-xfer**

This option is obsolete. It was used in BIND 8 to specify the pathname to the named-xfer program. In BIND 9, no separate named-xfer program is needed; its functionality is built into the name server.

### **tkey-domain**

The domain appended to the names of all shared keys generated with **TKEY**. When a client requests a **TKEY** exchange, it may or may not specify the desired name for the key. If present, the

name of the shared key is **client specified part + tkey-domain**. Otherwise, the name of the shared key is **random hex digits + tkey-domain**. In most cases, the **domainname** should be the server's domain name.

#### **tkey-dhkey**

The Diffie-Hellman key used by the server to generate shared keys with clients using the Diffie-Hellman mode of **TKEY**. The server must be able to load the public and private keys from files in the working directory. In most cases, the keyname should be the server's host name.

#### **dump-file**

The pathname of the file the server dumps the database to when instructed to do so with **rndc dumpdb**. If not specified, the default is **named\_dump.db**.

#### **memstatistics-file**

The pathname of the file the server writes memory usage statistics to on exit. If not specified, the default is **named.memstats**.

**Note:** Not yet implemented in BIND 9.

#### **pid-file**

The pathname of the file the server writes its process ID in. If not specified, the default is **/var/run/named.pid**. The pid-file is used by programs that want to send signals to the running nameserver.

#### **statistics-file**

The pathname of the file the server appends statistics to when instructed to do so using **rndc stats**. If not specified, the default is **named.stats** in the server's current directory.

**port** The UDP/TCP port number the server uses for receiving and sending DNS protocol traffic. The default is 53. This option is mainly intended for server testing; a server using a port other than 53 will not be able to communicate with the global DNS.

#### **random-device**

The source of entropy to be used by the server. Entropy is primarily needed for DNSSEC operations, such as **TKEY** transactions and dynamic update of signed zones. This option specifies the device (or file) from which to read entropy. If this is a file, operations requiring entropy fail when the file has been exhausted. If not specified, the default value is **/dev/random** (or equivalent) when present, and none otherwise. The random-device option takes effect during the initial configuration load at server startup time and is ignored on subsequent reloads.

## **Boolean Options**

#### **auth-nxdomain**

If yes, then the **AA** bit is always set on NXDOMAIN responses, even if the server is not actually authoritative. The default is no; this is a change from BIND 8. If you are using very old DNS software, you may need to set it to yes.

#### **deallocate-on-exit**

This option was used in BIND 8 to enable checking for memory leaks on exit. BIND 9 ignores the option and always performs the checks.

**dialup** If yes, the server treats all zones as if they are doing zone transfers across a dial on demand dialup link, which can be brought up by traffic originating from this server. This has different effects according to zone type and concentrates the zone maintenance so that it all happens in a short interval, once every **heartbeat-interval** and hopefully during the one call. It also suppresses some of the normal zone maintenance traffic. The default is no. The **dialup** option may also be specified in the **view** and **zone** statements, in which case it overrides the global **dialup** option.

If the zone is a master zone then the server sends out a NOTIFY request to all the slaves. This triggers the zone serial number check in the slave (providing it supports NOTIFY) allowing the slave to verify the zone while the connection is active.

If the zone is a slave or stub zone, then the server suppresses the regular "zone up to date" (refresh) queries and only perform them when the **heartbeat-interval** expires in addition to sending NOTIFY requests.

Finer control can be achieved by using **notify**, which only sends NOTIFY messages; **notify-passive**, which sends NOTIFY messages and suppresses the normal refresh queries; and **refresh**, which suppresses normal refresh processing and send refresh queries when the **heartbeat-interval** expires and **passive** which just disables normal refresh processing.

#### **fake-iquery**

In BIND 8, this option was used to enable simulating the obsolete DNS query type IQUERY. BIND 9 never does IQUERY simulation.

#### **fetch-glue**

This option is obsolete. In BIND 8, **fetch-glue yes** caused the server to attempt to fetch glue resource records it did not have when constructing the additional data section of a response. This is now considered bad practice, and BIND 9 never does it.

#### **has-old-clients**

This option was incorrectly implemented in BIND 8, and is ignored by BIND 9. To achieve the intended effect of **has-old-clients yes**, specify the two separate options **auth-nxdomain yes** and **rfc2308-type1 no** instead.

#### **host-statistics**

In BIND 8, this enables keeping of statistics for every host that the nameserver interacts with. It is not implemented in BIND 9.

#### **maintain-ixfr-base**

This option is obsolete. It was used in BIND 8 to determine whether a transaction log was kept for Incremental Zone Transfer. BIND 9 maintains a transaction log whenever possible. If you need to disable outgoing incremental zone transfers, use **provide-ixfr no**.

#### **minimal-responses**

If **yes**, then when generating responses, the server only adds records to the authority and additional data sections when they are required. This may improve the performance of the server. The default is **no**.

#### **multiple-cnames**

This option was used in BIND 8 to allow a domain name to allow multiple CNAME records in violation of the DNS standards. BIND 9.2 strictly enforces the CNAME rules both in master files and dynamic updates.

**notify** If **yes** (default), DNS NOTIFY messages are sent when a zone the server is authoritative for changes. The messages are sent to the servers listed in the zone's NS records (except the master server identified in the SOA MNAME field), and to any servers listed in the **also-notify** option. If **explicit**, notifies are sent only to servers explicitly listed using **also-notify**. If **no**, no notifies are sent.

The **notify** option may also be specified in the **zone** statement, in which case it overrides the **options notify** statement. It would only be necessary to turn off this option if it caused slaves to crash.

#### **recursion**

If **yes**, and a DNS query requests recursion, then the server attempts to do all the work required to answer the query. If recursion is off and the server does not already know the answer, it returns a referral response. The default is **yes**.

**Note:** Setting **recursion no** does not prevent clients from getting data from the cache on the server; it only prevents new data from being cached as an effect of client queries. Caching may still occur as an effect the server's internal operation, such as NOTIFY address lookups.

**rfc2308-type1**

Setting this to yes causes the server to send NS records along with the SOA record for negative answers. The default is no.

**Note:** Not yet implemented in BIND 9.

**use-id-pool**

This option is obsolete. BIND 9 always allocates query IDs from a pool.

**zone-statistics**

If yes, the server, by default, collects statistical data on all zones in the server. These statistics may be accessed using **rndc stats**, which dumps them to the file listed in the **statistics-file**. See "The Statistics File" on page 564.

**use-ixfr**

This option is obsolete. If you need to disable IXFR to a particular server or servers see the information on the provide-ixfr option in "Server Statement Definition and Usage" on page 565.

**provide-ixfr**

See the description of **provide-ixfr** in "Server Statement Definition and Usage" on page 565.

**request-ixfr**

See the description of **request-ixfr** in "Server Statement Definition and Usage" on page 565.

**treat-cr-as-space**

This option was used in BIND 8 to make the server treat carriage return ("\\r") characters the same way as a space or tab character to facilitate loading of zone files on a UNIX system that were generated on a Windows NT or DOS machine. In BIND 9, both UNIX "\\n" and NT/DOS "\\r\\n" newlines are always accepted, and the option is ignored.

**additional-from-auth, additional-from-cache**

These options control the behavior of an authoritative server when answering queries which have additional data, or when following CNAME and DNAME chains. When both of these options are set to yes (default) and a query is being answered from authoritative data (a zone configured into the server), the additional data section of the reply is filled in using data from other authoritative zones and from the cache. In some situations this is undesirable, such as when there is concern over the correctness of the cache, or in servers where slave zones may be added and modified by untrusted third parties. Also, avoiding the search for this additional data speeds up server operations at the possible expense of additional queries to resolve what would otherwise be provided in the additional section.

For example, if a query asks for an MX record for host `foo.example.com`, and the record found is "MX 10 mail.example.net", normally the address records for `mail.example.net` are provided as well, if known. Setting these options to no disables this behavior.

These options are intended for use in authoritative-only servers, or in authoritative-only views. Attempts to set them to no without also specifying **recursion no**; causes the server to ignore the options and log a warning message.

Specifying **additional-from-cache no** actually disables the use of the cache not only for additional data lookups but also when looking up the answer. This is usually the desired behavior in an authoritative-only server where the correctness of the cached data is an issue.

When a name server is non-recursively queried for a name that is not below the apex of any served zone, it normally answers with an "upwards referral" to the root servers or the servers of some other known parent of the query name. Since the data in an upwards referral comes from the cache, the server will not be able to provide upwards referrals when **additional-from-cache no** has been specified. Instead, it responds to such queries with REFUSED. This should not cause any problems since upwards referrals are not required for the resolution process.

**match-mapped-addresses**

If yes, then an IPv4-mapped IPv6 address matches any address match list entries that match the

corresponding IPv4 address. Enabling this option is sometimes useful on IPv6-enabled Linux systems, to work around a kernel quirk that causes IPv4 TCP connections such as zone transfers to be accepted on an IPv6 socket using mapped addresses, causing address match lists designed for IPv4 to fail to match. The use of this option for any other purpose is discouraged.

## Forwarding

The forwarding facility can be used to create a large site-wide cache on a few servers, reducing traffic over links to external nameservers. It can also be used to allow queries by servers that do not have direct access to the Internet, but wish to look up exterior names anyway. Forwarding occurs only on those queries for which the server is not authoritative and does not have the answer in its cache.

### forward

This option is only meaningful if the forwarders list is not empty. A value of first, the default, causes the server to query the forwarders first, and if that does not answer the question the server then looks for the answer itself. If only is specified, the server only queries the forwarders.

### forwarders

Specifies the IP addresses to be used for forwarding. The default is the empty list (no forwarding).

Forwarding can also be configured on a per-domain basis, allowing for the global forwarding options to be overridden in various ways. You can set particular domains to use different forwarders, or have a different forward only/first behavior, or not forward at all. See “Zone Statement Grammar” on page 567.

## Access Control

Access to the server can be restricted based on the IP address of the requesting system.

### allow-notify

Specifies which hosts are allowed to notify slaves of a zone change in addition to the zone masters. The **allow-notify** option may also be specified in the **zone** statement, in which case it overrides the **options allow-notify** statement. It is only meaningful for a slave zone. If not specified, the default is to process notify messages only from a zone's master.

### allow-query

Specifies which hosts are allowed to ask ordinary questions. The **allow-query** option may also be specified in the **zone** statement, in which case it overrides the **options allow-query** statement. If not specified, the default is to allow queries from all hosts.

### allow-recursion

Specifies which hosts are allowed to make recursive queries through this server. If not specified, the default is to allow recursive queries from all hosts. Note that disallowing recursive queries for a host does not prevent the host from retrieving data that is already in the cache on the server.

### allow-transfer

Specifies which hosts are allowed to receive zone transfers from the server. **allow-transfer** may also be specified in the **zone** statement, in which case it overrides the **options allow-transfer** statement. If not specified, the default is to allow transfers from all hosts.

### blackhole

Specifies a list of addresses that the server does not accept queries from or uses to resolve a query. Queries from these addresses are not responded to. The default is none.

## Interfaces

The interfaces and ports that the server answers queries from may be specified using the **listen-on** option. **listen-on** takes an optional port, and an **address\_match\_list**. The server listens on all interfaces allowed by the address match list. If a port is not specified, port 53 is used.

Multiple **listen-on** statements are allowed. For example:

```
listen-on { 5.6.7.8; };
listen-on port 1234 { !1.2.3.4; 1.2/16; };
```

This enables the nameserver on port 53 for the IP address 5.6.7.8, and on port 1234 of an address on the machine in net 1.2 that is not 1.2.3.4.

If no **listen-on** is specified, the server listens on port 53 on all interfaces.

## Query Address

If the server does not know the answer to a question, it queries other nameservers. **query-source** specifies the address and port used for such queries. If **address** is \* or is omitted, a wildcard IP address (**INADDR\_ANY**) is used. If **port** is \* or is omitted, a random unprivileged port is used. The defaults are as follows:

```
query-source address * port *;
query-source-v6 address * port *
```

**Note:** The address specified in the **query-source** option is used for both UDP and TCP queries, but the port applies only to UDP queries. TCP queries always use a random unprivileged port.

## Zone Transfers

BIND has mechanisms in place to facilitate zone transfers and set limits on the amount of load that transfers place on the system. The following options apply to zone transfers.

### also-notify

Defines a global list of IP addresses of name servers that are also sent NOTIFY messages whenever a fresh copy of the zone is loaded, in addition to the servers listed in the zone's NS records. This helps to ensure that copies of the zones quickly converge on stealth servers. If an **also-notify** list is given in a zone statement, it overrides the **options also-notify** statement. When a **zone notify** statement is set to no, the IP addresses in the global **also-notify** list are not sent NOTIFY messages for that zone. The default is the empty list (no global notification list).

### max-transfer-time-in

Inbound zone transfers running longer than this many minutes are terminated. The default is 120 minutes (2 hours).

### max-transfer-idle-in

Inbound zone transfers making no progress in this many minutes are terminated. The default is 60 minutes (1 hour).

### max-transfer-time-out

Outbound zone transfers running longer than this many minutes are terminated. The default is 120 minutes (2 hours).

### max-transfer-idle-out

Outbound zone transfers making no progress in this many minutes are terminated. The default is 60 minutes (1 hour).

### serial-query-rate

Slave servers periodically query master servers to find out if zone serial numbers have changed. Each such query uses a minute amount of the slave server's network bandwidth. To limit the amount of bandwidth used, BIND 9 limits the rate at which queries are sent. The value of the **serial-query-rate** option, an integer, is the maximum number of queries sent per second. The default is 20.

### serial-queries

In BIND 8, the **serial-queries** option set the maximum number of concurrent serial number

queries allowed to be outstanding at any given time. BIND 9 does not limit the number of outstanding serial queries and ignores the **serial-queries** option. Instead, it limits the rate at which the queries are sent as defined using the **serial-query-rate** option.

#### **transfer-format**

Zone transfers can be sent using two different formats, **one-answer** and **many-answers**. The **transfer-format** option is used on the master server to determine which format it sends.

**one-answer** uses one DNS message per resource record transferred. **many-answers** packs as many resource records as possible into a message. **many-answers** is more efficient, but is only supported by relatively new slave servers, such as BIND 9, BIND 8.x and patched versions of BIND 4.9.5. The default is **many-answers**. **transfer-format** may be overridden on a per-server basis by using the **server** statement.

#### **transfers-in**

The maximum number of inbound zone transfers that can be running concurrently. The default value is 10. Increasing **transfers-in** may speed up the convergence of slave zones, but it also may increase the load on the local system.

#### **transfers-out**

The maximum number of outbound zone transfers that can be running concurrently. Zone transfer requests in excess of the limit are refused. The default value is 10.

#### **transfers-per-ns**

The maximum number of inbound zone transfers that can be concurrently transferring from a given remote nameserver. The default value is 2. Increasing **transfers-per-ns** may speed up the convergence of slave zones, but it also may increase the load on the remote nameserver.

**transfers-per-ns** may be overridden on a per-server basis by using the **transfers** phrase of the **server** statement.

#### **transfer-source**

**transfer-source** determines which local address is bound to IPv4 TCP connections used to fetch zones transferred inbound by the server. It also determines the source IPv4 address, and optionally the UDP port, used for the refresh queries and forwarded dynamic updates. If not set, it defaults to a system controlled value which is usually the address of the interface "closest to" the remote end. This address must appear in the remote end's **allow-transfer** option for the zone being transferred, if one is specified. This statement sets the **transfer-source** for all zones, but can be overridden on a per-view or per-zone basis by including a **transfer-source** statement within the **view** or **zone** block in the configuration file.

#### **notify-source**

**notify-source** determines which local source address, and optionally UDP port, is used to send NOTIFY messages. This address must appear in the slave server's **masters zone** clause or in an **allow-notify** clause. This statement sets the **notify-source** for all zones, but can be overridden on a per-zone / per-view basis by including a **notify-source** statement within the **zone** or **view** block in the configuration file.

### **Operating System Resource Limits**

The server's usage of many system resources can be limited. Scaled values are allowed when specifying resource limits. For example, 1G can be used instead of **1073741824** to specify a limit of one gigabyte. The **unlimited** option requests unlimited use, or the maximum available amount. The **default** option uses the limit that was in force when the server was started.

The following options set operating system resource limits for the name server process. Some operating systems do not support some or any of the limits. On such systems, a warning is issued if the unsupported limit is used.

#### **coresize**

The maximum size of a core dump. The default is **default**.

### **datasize**

The maximum amount of data memory the server may use. The default is `default`. This is a hard limit on server memory usage. If the server attempts to allocate memory in excess of this limit, the allocation fails, which may in turn leave the server unable to perform DNS service. Therefore, this option is rarely useful as a way of limiting the amount of memory used by the server, but it can be used to raise an operating system data size limit that is too small by default. If you wish to limit the amount of memory used by the server, use the **max-cache-size** and **recursive-clients** options instead.

**files** The maximum number of files the server may have open concurrently. The default is `unlimited`.

### **stacksize**

The maximum amount of stack memory the server may use. The default is `default`.

## **Server Resource Limits**

The following options set limits on the server's resource consumption that are enforced internally by the server rather than the operating system.

### **max-ixfr-log-size**

This option is obsolete; it is accepted and ignored for BIND 8 compatibility.

### **recursive-clients**

The maximum number of simultaneous recursive lookups the server performs on behalf of clients. The default is 1000. Because each recursing client uses a fair bit of memory, on the order of 20 KB, the value of the **recursive-clients** option may have to be decreased on hosts with limited memory.

### **tcp-clients**

The maximum number of simultaneous client TCP connections that the server accepts. The default is 100.

### **max-cache-size**

The maximum amount of memory to use for the cache on the server, in bytes. When the amount of data in the cache reaches this limit, the server causes the records to expire prematurely so that the limit is not exceeded. In a server with multiple views, the limit applies separately to the cache of each view. The default value is `unlimited`, indicating that records are purged from the cache only when their TTLs expire. The minimum value that you can set for this limit is 2 MB.

## **Periodic Task Intervals**

### **cleaning-interval**

The server removes expired resource records from the cache every **cleaning-interval** minutes. The default is 60 minutes. If set to 0, periodic cleaning does not occur.

### **heartbeat-interval**

The server performs zone maintenance tasks for all zones marked as `dialup` whenever this interval expires. The default is 60 minutes. Reasonable values are up to 1 day (1440 minutes). If set to 0, zone maintenance for these zones does not occur.

### **interface-interval**

The server scans the network interface list every **interface-interval** minutes. The default is 60 minutes. If set to 0, interface scanning only occurs when the configuration file is loaded. After the scan, listeners are started on any new interfaces (provided they are allowed by the **listen-on** configuration). Listeners on interfaces that have gone away are cleaned up.

### **statistics-interval**

Nameserver statistics are logged every **statistics-interval** minutes. The default is 60. If set to 0, no statistics are logged.

**Note:** Not yet implemented in BIND 9.

## Topology

All other things being equal, when the server chooses a nameserver to query from a list of nameservers, it prefers the one that is topologically closest to itself. The **topology** statement takes an **address\_match\_list** and interprets it in a special way. Each top-level list element is assigned a distance. Non-negated elements get a distance based on their position in the list, where the closer the match is to the start of the list, the shorter the distance is between it and the server. A negated match is assigned the maximum distance from the server. If there is no match, the address gets a distance which is further than any non-negated list element, and closer than any negated element. For example,

```
topology {
 10/8;
 !1.2.3/24;
 { 1.2/16; 3/8; };
};
```

prefers servers on network 10 the most, followed by hosts on network 1.2.0.0 (netmask 255.255.0.0) and network 3, except for hosts on network 1.2.3 (netmask 255.255.255.0), which is preferred least of all.

The default topology is

```
topology { localhost; localnets; };
```

**Note:** The **topology** option is not implemented in BIND 9.

## The sortlist Statement

The response to a DNS query may consist of multiple resource records (RRs) forming a resource records set (RRset). The name server normally returns the RRs within the RRset in an indeterminate order (but see the **rrset-order** statement in “RRset Ordering” on page 563). The client resolver code should rearrange the RRs as appropriate, that is, using any addresses on the local net in preference to other addresses. However, not all resolvers can do this or are correctly configured. When a client is using a local server the sorting can be performed in the server, based on the client's address. This only requires configuring the nameservers, not all the clients.

The **sortlist** statement (see below) takes an **address\_match\_list** and interprets it even more specifically than the **topology** statement does (“Topology”). Each top-level statement in the **sortlist** must itself be an explicit **address\_match\_list** with one or two elements. The first element (which may be an IP address, an IP prefix, an ACL name or a nested **address\_match\_list**) of each top-level list is checked against the source address of the query until a match is found.

Once the source address of the query has been matched, if the top-level statement contains only one element, the actual primitive element that matched the source address is used to select the address in the response to move to the beginning of the response. If the statement is a list of two elements, then the second element is treated the same as the **address\_match\_list** in a **topology** statement. Each top-level element is assigned a distance and the address in the response with the minimum distance is moved to the beginning of the response.

In the following example, any queries received from any of the addresses of the host itself get responses preferring addresses on any of the locally connected networks. Next most preferred are addresses on the 192.168.1/24 network, and after that either the 192.168.2/24 or 192.168.3/24 network with no preference shown between these two networks. Queries received from a host on the 192.168.1/24 network prefer

other addresses on that network to the 192.168.2/24 and 192.168.3/24 networks. Queries received from a host on the 192.168.4/24 or the 192.168.5/24 network only prefer other addresses on their directly connected networks.

```
sortlist {
 { localhost; // IF the local host
 { localnets; // THEN first fit on the
 192.168.1/24; // following nets
 { 192.168.2/24; 192.168.3/24; }; }; };
 { 192.168.1/24; // IF on class C 192.168.1
 { 192.168.1/24; // THEN use .1, or .2 or .3
 { 192.168.2/24; 192.168.3/24; }; }; };
 { 192.168.2/24; // IF on class C 192.168.2
 { 192.168.2/24; // THEN use .2, or .1 or .3
 { 192.168.1/24; 192.168.3/24; }; }; };
 { 192.168.3/24; // IF on class C 192.168.3
 { 192.168.3/24; // THEN use .3, or .1 or .2
 { 192.168.1/24; 192.168.2/24; }; }; };
 { { 192.168.4/24; 192.168.5/24; }; // if .4 or .5, prefer that net
 };
};
```

The following example gives reasonable behavior for the local host and hosts on directly connected networks. It is similar to the behavior of the address sort in BIND 4.9.x. Responses sent to queries from the local host favor any of the directly connected networks. Responses sent to queries from any other hosts on a directly connected network prefer addresses on that same network. Responses to other queries are not sorted.

```
sortlist {
 { localhost; localnets; };
 { localnets; };
};
```

## RRset Ordering

When multiple records are returned in an answer it may be useful to configure the order of the records placed into the response. The **rrset-order** statement permits configuration of the ordering of the records in a multiple record response. See also the **sortlist** statement, “The sortlist Statement” on page 562.

An **order\_spec** is defined as follows:

```
[class class_name][type type_name][name "domain_name"]
 order ordering
```

If no class is specified, the default is **ANY**. If no type is specified, the default is **ANY**. If no name is specified, the default is “\*”.

The legal values for **ordering** are:

| Item          | Description                                                          |
|---------------|----------------------------------------------------------------------|
| <b>fixed</b>  | Records are returned in the order they are defined in the zone file. |
| <b>random</b> | Records are returned in some random order.                           |
| <b>cyclic</b> | Records are returned in a round-robin order.                         |

For example:

```
rrset-order {
 class IN type A name "host.example.com" order random;
 order cyclic;
};
```

causes any responses for type A records in class IN that have " host.example.com" as a suffix, to always be returned in random order. All other records are returned in cyclic order.

If multiple **rrset-order** statements appear, they are not combined — the last one applies.

**Note:** The **rrset-order** statement is not yet implemented in BIND 9. BIND 9 currently supports only a "random-cyclic" ordering, where the server randomly chooses a starting point within the RRset and returns the records in order starting at that point, wrapping around the end of the RRset if necessary.

## Tuning

### **lame-ttl**

Sets the number of seconds to cache a lame server indication. 0 disables caching. (This is not recommended.) Default is 600 (10 minutes). Maximum value is 1800 (30 minutes).

### **max-nocache-ttl**

To reduce network traffic and increase performance the server stores negative answers. **max-nocache-ttl** is used to set a maximum retention time for these answers in the server in seconds. The default **max-nocache-ttl** is 10800 seconds (3 hours). **max-nocache-ttl** cannot exceed 7 days and is silently truncated to 7 days if set to a greater value.

### **max-cache-ttl**

**max-cache-ttl** sets the maximum time for which the server will cache ordinary (positive) answers. The default is one week (7 days).

### **min-roots**

The minimum number of root servers that is required for a request for the root servers to be accepted. Default is 2.

**Note:** Not yet implemented in BIND 9.

### **sig-validity-interval**

Specifies the number of days into the future when DNSSEC signatures automatically generated as a result of dynamic updates ((Section 4.1)) will expire. The default is 30 days. The signature inception time is unconditionally set to one hour before the current time to allow for a limited amount of clock skew.

### **min-refresh-time, max-refresh-time, min-retry-time, max-retry-time**

These options control the server's behavior on refreshing a zone (querying for SOA changes) or retrying failed transfers. Usually the SOA values for the zone are used, but these values are set by the master, giving slave server administrators little control over their contents.

These options allow the administrator to set a minimum and maximum refresh and retry time either per-zone, per-view, or per-server. These options are valid for master, slave and stub zones, and clamp the SOA refresh and retry times to the specified values.

## The Statistics File

The statistics file generated by BIND 9 is similar, but not identical, to that generated by BIND 8.

The statistics dump begins with the line **+++ Statistics Dump +++ (973798949)**, where the number in parentheses is a standard UNIX-style timestamp, measured as seconds since January 1, 1970. Following that line, are a series of lines containing a counter type, the value of the counter, optionally a zone name, and optionally a view name. The lines without view and zone listed are global statistics for the entire server. Lines with a zone and view name for the given view and zone (the view name is omitted for the default view). The statistics dump ends with the line **--- Statistics Dump --- (973798949)**, where the number is identical to the number in the beginning line.

The following statistics counters are maintained:

| Item             | Description                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>success</b>   | The number of successful queries made to the server or zone. A successful query is defined as a query which returns a NOERROR response other than a referral response. |
| <b>referral</b>  | The number of queries which resulted in referral responses.                                                                                                            |
| <b>nxrset</b>    | The number of queries which resulted in NOERROR responses with no data.                                                                                                |
| <b>nxdomain</b>  | The number of queries which resulted in NXDOMAIN responses.                                                                                                            |
| <b>recursion</b> | The number of queries which caused the server to perform recursion in order to find the final answer.                                                                  |
| <b>failure</b>   | The number of queries which resulted in a failure response other than those above.                                                                                     |

### server Statement Grammar

```
server ip_addr {
 [bogus yes_or_no ;]
 [provide-ixfr yes_or_no ;]
 [request-ixfr yes_or_no ;]
 [edns yes_or_no ;]
 [transfers number ;]
 [transfer-format (one-answer | many-answers) ;]]
 [keys { string ; [string ; [...]] } ;]
};
```

## Server Statement Definition and Usage

The **server** statement defines characteristics to be associated with a remote nameserver.

The **server** statement can occur at the top level of the configuration file or inside a **view** statement. If a **view** statement contains one or more **server** statements, only those apply to the view and any top-level ones are ignored. If a view contains no **server** statements, any top-level **server** statements are used as defaults.

If you discover that a remote server is giving out bad data, marking it as **bogus** prevents further queries to it. The default value of **bogus** is **no**.

The **provide-ixfr** clause determines whether the local server, acting as master, responds with an incremental zone transfer when the given remote server, a slave, requests it. If set to **yes**, incremental transfer is provided whenever possible. If set to **no**, all transfers to the remote server are nonincremental. If not set, the value of the **provide-ixfr** option in the view or global options block is used as a default.

The **request-ixfr** clause determines whether the local server, acting as a slave, requests incremental zone transfers from the given remote server, a master. If not set, the value of the **request-ixfr** option in the view or global options block is used as a default.

IXFR requests to servers that do not support IXFR automatically fall back to AXFR. Therefore, there is no need to manually list which servers support IXFR and which ones do not; the global default of **yes** should always work. The purpose of the **provide-ixfr** and **request-ixfr** clauses is to make it possible to disable the use of IXFR even when both master and slave claim to support it, for example if one of the servers is buggy and crashes or corrupts data when IXFR is used.

The **edns** clause determines whether the local server will attempt to use EDNS when communicating with the remote server. The default is **yes**.

The server supports two zone transfer methods. The first, **one-answer**, uses one DNS message per resource record transferred. **many-answers** packs as many resource records as possible into a message. **many-answers** is more efficient, but is only known to be understood by BIND 9, BIND 8.x, and patched versions of BIND 4.9.5. You can specify which method to use for a server with the **transfer-format** option. If **transfer-format** is not specified, the **transfer-format** specified by the **options** statement is used.

**transfers** is used to limit the number of concurrent inbound zone transfers from the specified server. If no **transfers** clause is specified, the limit is set according to the **transfers-per-ns** option.

The **keys** clause is used to identify a **key\_id** defined by the **key** statement, to be used for transaction security when talking to the remote server. The **key** statement must come before the **server** statement that references it. When a request is sent to the remote server, a request signature is generated using the key specified here and appended to the message. A request originating from the remote server is not required to be signed by this key.

Although the grammar of the **keys** clause allows for multiple keys, only a single key per server is currently supported.

#### **trusted-keys Statement Grammar**

```
trusted-keys {
 string number number number string ;
 [string number number number string ; [...]]
};
```

#### **trusted-keys Statement Definition and Usage**

The **trusted-keys** statement defines DNSSEC security roots. A security root is defined when the public key for a non-authoritative zone is known, but cannot be securely obtained through DNS, either because it is the DNS root zone or its parent zone is unsigned. Once a key has been configured as a trusted key, it is treated as if it had been validated and proven secure. The resolver attempts DNSSEC validation on all DNS data in subdomains of a security root.

The **trusted-keys** statement can contain multiple key entries, each consisting of the key's domain name, flags, protocol, algorithm, and the base-64 representation of the key data.

#### **view Statement Grammar**

```
view view_name [class] {
 match-clients { address_match_list } ;
 match-destinations { address_match_list } ;
 match-recursive-only { yes_or_no } ;
 [view_option; ...]
 [zone-statistics yes_or_no ;]
 [zone_statement; ...]
};
```

#### **6.2.20. view Statement Definition and Usage**

The **view** statement is a powerful new feature of BIND 9 that lets a name server answer a DNS query differently depending on who is asking. It is particularly useful for implementing split DNS setups without having to run multiple servers.

Each **view** statement defines a view of the DNS namespace that is seen by a subset of clients. A client matches a view if its source IP address matches the **address\_match\_list** of the view's **match-clients** clause and its destination IP address matches the **address\_match\_list** of the view's **match-destinations**

clause. If not specified, both **match-clients** and **match-destinations** default to matching all addresses. A view can also be specified as **match-recursive-only**, which means that only recursive requests from matching clients match that view. The order of the **view** statements is significant — a client request is resolved in the context of the first **view** that it matches.

Zones defined within a **view** statement are only accessible to clients that match the **view**. By defining a zone of the same name in multiple views, different zone data can be given to different clients, for example, "internal" and "external" clients in a split DNS setup.

Many of the options given in the **options** statement can also be used within a **view** statement, and then apply only when resolving queries with that view. When no view-specific value is given, the value in the **options** statement is used as a default. Also, zone options can have default values specified in the **view** statement; these view-specific defaults take precedence over those in the **options** statement.

Views are class-specific. If no class is given, class IN is assumed. Note that all non-IN views must contain a hint zone, since only the IN class has compiled-in default hints.

If there are no **view** statements in the config file, a default view that matches any client is automatically created in class IN, and any **zone** statements specified on the top level of the configuration file are considered to be part of this default view. If any explicit **view** statements are present, all **zone** statements must occur inside **view** statements.

Here is an example of a typical split DNS setup implemented using **view** statements.

```
view "internal" {
 // This should match our internal networks.
 match-clients { 10.0.0.0/8; };
 // Provide recursive service to internal clients only.
 recursion yes;
 // Provide a complete view of the example.com zone
 // including addresses of internal hosts.
 zone "example.com" {
 type master;
 file "example-internal.db";
 };
};

view "external" {
 match-clients { any; };
 // Refuse recursive service to external clients.
 recursion no;
 // Provide a restricted view of the example.com zone
 // containing only publicly accessible hosts.
 zone "example.com" {
 type master;
 file "example-external.db";
 };
};
```

## Zone Statement Grammar

```
zone zone_name [class] [{
 type (master | slave | hint | stub | forward) ;
 [allow-notify { address_match_list } ;]
 [allow-query { address_match_list } ;]
 [allow-transfer { address_match_list } ;]
 [allow-update { address_match_list } ;]
 [update-policy { update_policy_rule [...] } ;]
 [allow-update-forwarding { address_match_list } ;]
 [also-notify { ip_addr [port ip_port] ; [ip_addr [port ip_port] ; ...] } ;]
 [check-names (warn|fail|ignore) ;]
 [dialup dialup_option ;]
 [file string ;]
 [forward (only|first) ;]
```

```

[forwarders { ip_addr [port ip_port] ; [ip_addr [port ip_port] ; ...] } ;]
[ixfr-base string ;]
[ixfr-tmp-file string ;]
[maintain-ixfr-base yes_or_no ;]
[masters [port ip_port] { ip_addr [port ip_port] [key key]; [...] } ;]
[max-ixfr-log-size number ;]
[max-transfer-idle-in number ;]
[max-transfer-idle-out number ;]
[max-transfer-time-in number ;]
[max-transfer-time-out number ;]
[notify yes_or_no | explicit ;]
[pubkey number number number string ;]
[transfer-source (ip4_addr | *) [port ip_port] ;]
[transfer-source-v6 (ip6_addr | *) [port ip_port] ;]
[notify-source (ip4_addr | *) [port ip_port] ;]
[notify-source-v6 (ip6_addr | *) [port ip_port] ;]
[zone-statistics yes_or_no ;]
[sig-validity-interval number ;]
[database string ;]
[min-refresh-time number ;]
[max-refresh-time number ;]
[min-retry-time number ;]
[max-retry-time number ;]
];

```

## **zone Statement Definition and Usage**

### **Zone Types**

| Item          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>master</b> | The server has a master copy of the data for the zone and will be able to provide authoritative answers for it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>slave</b>  | A slave zone is a replica of a master zone. The <b>masters</b> list specifies one or more IP addresses of master servers that the slave contacts to update its copy of the zone. By default, transfers are made from port 53 on the servers; this can be changed for all servers by specifying a port number before the list of IP addresses, or on a per-server basis after the IP address. Authentication to the master can also be done with per-server TSIG keys. If a file is specified, then the replica is written to this file whenever the zone is changed, and reloaded from this file on a server restart. Use of a file is recommended, since it often speeds server start-up and eliminates a needless waste of bandwidth. Note that for large numbers (in the tens or hundreds of thousands) of zones per server, it is best to use a two level naming scheme for zone file names. For example, a slave server for the zone <code>example.com</code> might place the zone contents into a file called <code>ex/example.com</code> where <code>ex/</code> is just the first two letters of the zone name. (Most operating systems behave very slowly if you put 100K files into a single directory.)                                                                                                                                                                                                                                |
| <b>stub</b>   | A stub zone is similar to a slave zone, except that it replicates only the NS records of a master zone instead of the entire zone. Stub zones are not a standard part of the DNS; they are a feature specific to the BIND implementation.<br><br>Stub zones can be used to eliminate the need for glue NS record in a parent zone at the expense of maintaining a stub zone entry and a set of name server addresses in <code>named.conf</code> . This usage is not recommended for new configurations, and BIND 9 supports it only in a limited way. In BIND 4/8, zone transfers of a parent zone included the NS records from stub children of that zone. This meant that, in some cases, users could get away with configuring child stubs only in the master server for the parent zone. BIND 9 never mixes together zone data from different zones in this way. Therefore, if a BIND 9 master serving a parent zone has child stub zones configured, all the slave servers for the parent zone also need to have the same child stub zones configured.<br><br>Stub zones can also be used as a way of forcing the resolution of a given domain to use a particular set of authoritative servers. For example, the caching name servers on a private network using RFC2157 addressing may be configured with stub zones for <code>10.in-addr.arpa</code> to use a set of internal name servers as the authoritative servers for that domain. |

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| forward | A "forward zone" is a way to configure forwarding on a per-domain basis. A <b>zone</b> statement of type <b>forward</b> can contain a <b>forward</b> and/or <b>forwarders</b> statement, which will apply to queries within the domain given by the zone name. If no <b>forwarders</b> statement is present or an empty list for <b>forwarders</b> is given, then no forwarding is done for the domain, canceling the effects of any forwarders in the <b>options</b> statement. Thus if you want to use this type of zone to change the behavior of the global <b>forward</b> option (that is, "forward first to", then "forward only", or vice versa, but want to use the same servers as set globally) you need to respecify the global forwarders. |
| hint    | The initial set of root nameservers is specified using a "hint zone". When the server starts up, it uses the root hints to find a root nameserver and get the most recent list of root nameservers. If no hint zone is specified for class IN, the server uses a compiled-in default set of root servers hints. Classes other than IN have no built-in defaults hints.                                                                                                                                                                                                                                                                                                                                                                                 |

## Class

The zone's name may optionally be followed by a class. If a class is not specified, class IN (for Internet), is assumed. This is correct for the vast majority of cases.

The **hesiod** class is named for an information service from MIT's Project Athena. It is used to share information about various systems databases, such as users, groups, printers, and so on. The keyword HS is a synonym for hesiod.

Another MIT development is CHAOSnet, a LAN protocol created in the mid-1970s. Zone data for it can be specified with the **CHAOS** class.

## Zone Options

### allow-notify

See the description of **allow-notify** in "Access Control" on page 558.

### allow-query

See the description of **allow-query** in "Access Control" on page 558.

### allow-transfer

See the description of **allow-transfer** in "Access Control" on page 558.

### allow-update

Specifies which hosts are allowed to submit Dynamic DNS updates for master zones. The default is to deny updates from all hosts.

### update-policy

Specifies a "Simple Secure Update" policy. See "Dynamic Update Policies" on page 571.

### allow-update-forwarding

Specifies which hosts are allowed to submit Dynamic DNS updates to slave zones to be forwarded to the master. The default is { none; }, which means that no update forwarding is performed. To enable update forwarding, specify **allow-update-forwarding { any; }**. Specifying values other than { none; } or { any; } is usually counterproductive, since the responsibility for update access control should rest with the master server, not the slaves.

Note that enabling the update forwarding feature on a slave server may expose master servers relying on insecure IP address based access control to attacks.

### also-notify

Only meaningful if **notify** is active for this zone. The set of machines that will receive a DNS NOTIFY message for this zone is made up of all the listed nameservers (other than the primary master) for the zone plus any IP addresses specified with **also-notify**. A port may be specified with each **also-notify** address to send the notify messages to a port other than the default of 53. **also-notify** is not meaningful for stub zones. The default is the empty list.

#### **check-names**

This option was used in BIND 8 to restrict the character set of domain names in master files or DNS responses received from the network. BIND 9 does not restrict the character set of domain names and does not implement the **check-names** option.

#### **database**

Specify the type of database to be used for storing the zone data. The string following the **database** keyword is interpreted as a list of whitespace-delimited words. The first word identifies the database type, and any subsequent words are passed as arguments to the database to be interpreted in a way specific to the database type.

The default is "rbt", BIND 9's native in-memory red-black-tree database. This database does not take arguments.

Other values are possible if additional database drivers have been linked into the server. Some sample drivers are included with the distribution but none are linked in by default.

#### **dialup**

See the description of **dialup** in "Boolean Options" on page 555.

#### **forward**

Only meaningful if the zone has a forwarders list. The **only** value causes the lookup to fail after trying the forwarders and getting no answer, while **first** would allow a normal lookup to be tried.

#### **forwarders**

Used to override the list of global forwarders. If it is not specified in a zone of type **forward**, no forwarding is done for the zone; the global options are not used.

#### **ixfr-base**

Was used in BIND 8 to specify the name of the transaction log (journal) file for dynamic update and IXFR. BIND 9 ignores the option and constructs the name of the journal file by appending ".jnl" to the name of the zone file.

#### **ixfr-tmp-file**

Was an undocumented option in BIND 8. Ignored in BIND 9.

#### **max-transfer-time-in**

See the description of **max-transfer-time-in** in "Zone Transfers" on page 559.

#### **max-transfer-idle-in**

See the description of **max-transfer-idle-in** in "Zone Transfers" on page 559.

#### **max-transfer-time-out**

See the description of **max-transfer-time-out** in "Zone Transfers" on page 559.

#### **max-transfer-idle-out**

See the description of **max-transfer-idle-out** in "Zone Transfers" on page 559.

#### **notify**

See the description of **notify** in "Boolean Options" on page 555.

## **pubkey**

In BIND 8, this option was intended for specifying a public zone key for verification of signatures in DNSSEC signed zones when they are loaded from disk. BIND 9 does not verify signatures on loading and ignores the option.

## **zone-statistics**

If yes, the server keeps statistical information for this zone, which can be dumped to the **statistics-file** defined in the server options.

## **sig-validity-interval**

See the description of **sig-validity-interval** in “Tuning” on page 564.

## **transfer-source**

See the description of **transfer-source** in “Zone Transfers” on page 559

## **notify-source**

See the description of **notify-source** in “Zone Transfers” on page 559

## **min-refresh-time, max-refresh-time, min-retry-time, max-retry-time**

See the description in “Tuning” on page 564.

## **Dynamic Update Policies**

BIND 9 supports two alternative methods of granting clients the right to perform dynamic updates to a zone, configured by the **allow-update** and **update-policy** option, respectively.

The **allow-update** clause works the same way as in previous versions of BIND. It grants given clients the permission to update any record of any name in the zone.

The **update-policy** clause is new in BIND 9 and allows more fine-grained control over what updates are allowed. A set of rules is specified, where each rule either grants or denies permissions for one or more names to be updated by one or more identities. If the dynamic update request message is signed (that is, it includes either a TSIG or SIG(0) record), the identity of the signer can be determined.

Rules are specified in the **update-policy** zone option, and are only meaningful for master zones. When the **update-policy** statement is present, it is a configuration error for the **allow-update** statement to be present. The **update-policy** statement only examines the signer of a message; the source address is not relevant.

This is how a rule definition looks:

```
(grant | deny) identity nametype name [types]
```

Each rule grants or denies privileges. Once a message has successfully matched a rule, the operation is immediately granted or denied and no further rules are examined. A rule is matched when the signer matches the identity field, the name matches the name field, and the type is specified in the type field.

The identity field specifies a name or a wildcard name. The nametype field has 4 values: name, subdomain, wildcard, and self

| Item      | Description                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------|
| name      | Matches when the updated name is the same as the name in the name field.                                     |
| subdomain | Matches when the updated name is a subdomain of the name in the name field (which includes the name itself). |
| wildcard  | Matches when the updated name is a valid expansion of the wildcard name in the name field.                   |
| self      | Matches when the updated name is the same as the message signer. The name field is ignored.                  |

If no types are specified, the rule matches all types except SIG, NS, SOA, and NXT. Types may be specified by name, including "ANY" (ANY matches all types except NXT, which can never be updated).

## Zone File

### DOMAIN Data File, DOMAIN Reverse Data File, DOMAIN Cache File, and DOMAIN Local

#### Types of Resource Records and When to Use Them

This section, largely borrowed from RFC 1034, describes the concept of a Resource Record (RR) and explains when each is used. Since the publication of RFC 1034, several new RRs have been identified and implemented in the DNS. These are also included.

#### Resource Records

A domain name identifies a node. Each node has a set of resource information, which may be empty. The set of resource information associated with a particular name is composed of separate RRs. The order of RRs in a set is not significant and need not be preserved by nameservers, resolvers, or other parts of the DNS. However, sorting of multiple RRs is permitted for optimization purposes, for example, to specify that a particular nearby server be tried first. See “The sortlist Statement” on page 562 and “RRset Ordering” on page 563.

The components of a Resource Record are:

| Item       | Description                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| owner name | the domain name where the RR is found.                                                                                                                                                                                |
| type       | an encoded 16 bit value that specifies the type of the resource in this resource record. Types refer to abstract resources.                                                                                           |
| TTL        | the time to live of the RR. This field is a 32 bit integer in units of seconds, and is primarily used by resolvers when they cache RRs. The TTL describes how long an RR can be cached before it should be discarded. |
| class      | an encoded 16 bit value that identifies a protocol family or instance of a protocol.                                                                                                                                  |
| RDATA      | the type and sometimes class-dependent data that describes the resource.                                                                                                                                              |

The following are *types* of valid RRs (some of these listed, although not obsolete, are experimental (x) or historical (h) and no longer in general use):

| <b>Item</b> | <b>Description</b>                                                                                                                                                                                       |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A           | a host address.                                                                                                                                                                                          |
| A6          | an IPv6 address.                                                                                                                                                                                         |
| AAAA        | Obsolete format of IPv6 address                                                                                                                                                                          |
| AFSDB       | (x) location of AFS® database servers. Experimental.                                                                                                                                                     |
| CNAME       | identifies the canonical name of an alias.                                                                                                                                                               |
| DNAME       | for delegation of reverse addresses. Replaces the domain name specified with another name to be looked up. Described in RFC 2672.                                                                        |
| HINFO       | identifies the CPU and OS used by a host.                                                                                                                                                                |
| ISDN        | (x) representation of ISDN addresses. Experimental.                                                                                                                                                      |
| KEY         | stores a public key associated with a DNS name.                                                                                                                                                          |
| LOC         | (x) for storing GPS info. See RFC 1876. Experimental.                                                                                                                                                    |
| MX          | identifies a mail exchange for the domain. See RFC 974 for details.                                                                                                                                      |
| NS          | the authoritative nameserver for the domain.                                                                                                                                                             |
| NXT         | used in DNSSEC to securely indicate that RRs with an owner name in a certain name interval do not exist in a zone and indicate what RR types are present for an existing name. See RFC 2535 for details. |
| PTR         | a pointer to another part of the domain name space.                                                                                                                                                      |
| RP          | (x) information on persons responsible for the domain. Experimental.                                                                                                                                     |
| RT          | (x) route-through binding for hosts that do not have their own direct wide area network addresses. Experimental.                                                                                         |
| SIG         | ("signature") contains data authenticated in the secure DNS. See RFC 2535 for details.                                                                                                                   |
| SOA         | identifies the start of a zone of authority.                                                                                                                                                             |
| SRV         | information about well known network services (replaces WKS).                                                                                                                                            |
| WKS         | (h) information about which well known network services, such as SMTP, that a domain supports. Historical, replaced by newer RR SRV.                                                                     |
| X25         | (x) representation of X.25 network addresses. Experimental.                                                                                                                                              |

The following *classes* of resource records are currently valid in the DNS:

| Item | Description                                                            |
|------|------------------------------------------------------------------------|
| IN   | For information about other, older classes of RRs the Internet system. |

RDATA is the type-dependent or class-dependent data that describes the resource:

| Item  | Description                                                                                                                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| A     | for the IN class, a 32 bit IP address.                                                                                                                                                                      |
| A6    | maps a domain name to an IPv6 address, with a provision for indirection for leading "prefix" bits.                                                                                                          |
| CNAME | a domain name.                                                                                                                                                                                              |
| DNAME | provides alternate naming to an entire subtree of the domain name space, rather than to a single node. It causes some suffix of a queried name to be substituted with a name from the DNAME record's RDATA. |
| MX    | a 16 bit preference value (lower is better) followed by a host name willing to act as a mail exchange for the owner domain.                                                                                 |
| NS    | a fully qualified domain name.                                                                                                                                                                              |
| PTR   | a fully qualified domain name.                                                                                                                                                                              |
| SOA   | several fields.                                                                                                                                                                                             |

The owner name is often implicit, rather than forming an integral part of the RR. For example, many nameservers internally form tree or hash structures for the name space, and chain RRs off nodes. The remaining RR parts are the fixed header (type, class, TTL) which is consistent for all RRs, and a variable part (RDATA) that fits the needs of the resource being described.

The meaning of the TTL field is a time limit on how long an RR can be kept in a cache. This limit does not apply to authoritative data in zones; it is also timed out, but by the refreshing policies for the zone. The TTL is assigned by the administrator for the zone where the data originates. While short TTLs can be used to minimize caching, and a zero TTL prohibits caching, the realities of Internet performance suggest that these times should be on the order of days for the typical host. If a change can be anticipated, the TTL can be reduced prior to the change to minimize inconsistency during the change, and then increased back to its former value following the change.

The data in the RDATA section of RRs is carried as a combination of binary strings and domain names. The domain names are frequently used as "pointers" to other data in the DNS.

### Textual expression of RRs

RRs are represented in binary form in the packets of the DNS protocol, and are usually represented in highly encoded form when stored in a nameserver or resolver. In the examples provided in RFC 1034, a style similar to that used in master files was employed in order to show the contents of RRs. In this format, most RRs are shown on a single line, although continuation lines are possible using parentheses.

The start of the line gives the owner of the RR. If a line begins with a blank, then the owner is assumed to be the same as that of the previous RR. Blank lines are often included for readability.

Following the owner, we list the TTL, type, and class of the RR. Class and type use the mnemonics defined above, and TTL is an integer before the type field. In order to avoid ambiguity in parsing, type and class mnemonics are disjoint, TTLs are integers, and the type mnemonic is always last. The IN class and TTL values are often omitted from examples in the interests of clarity.

The resource data or RDATA section of the RR are given using knowledge of the typical representation for the data.

For example, we might show the RRs carried in a message as:

| Item           | Description | Value              |
|----------------|-------------|--------------------|
| ISI.EDU.       | MX          | 10 VENERA.ISI.EDU. |
|                | MX          | 10 VAXA.ISI.EDU    |
| VENERA.ISI.EDU | A           | 128.9.0.32         |
|                | A           | 10.1.0.52          |
| VAXA.ISI.EDU   | A           | 10.2.0.27          |
|                | A           | 128.9.0.33         |

The MX RRs have an RDATA section which consists of a 16 bit number followed by a domain name. The address RRs use a standard IP address format to contain a 32 bit internet address.

This example shows six RRs, with two RRs at each of three domain names.

Similarly we might see:

| Item               | Description | Value         |
|--------------------|-------------|---------------|
| XX.LCS/MIT.EDU. IN | A           | 10.0.0.44     |
| CH                 | A           | MIT.EDU. 2420 |

This example shows two addresses for XX.LCS/MIT.EDU, each of a different class.

### Discussion of MX Records

As described above, domain servers store information as a series of resource records, each of which contains a particular piece of information about a given domain name (which is usually, but not always, a host). The simplest way to think of an RR is as a typed pair of datum, a domain name matched with relevant data, and stored with some additional type information to help systems determine when the RR is relevant.

MX records are used to control delivery of email. The data specified in the record is a priority and a domain name. The priority controls the order in which email delivery is attempted, with the lowest number first. If two priorities are the same, a server is chosen randomly. If no servers at a given priority are responding, the mail transport agent falls back to the next largest priority. Priority numbers do not have any absolute meaning — they are relevant only respective to other MX records for that domain name. The domain name given is the machine to which the mail is delivered. It must have an associated A record — CNAME is not sufficient.

For a given domain, if there is both a CNAME record and an MX record, the MX record is in error, and is ignored. Instead, the mail is delivered to the server specified in the MX record pointed to by the CNAME.

```

example.com. IN MX 10 mail.example.com.
 IN MX 10 mail2.example.com.
 IN MX 10 mail.backup.org.
mail.example.com. IN A 10.0.0.1
mail2.example.com. IN A 10.0.0.2

```

For example:

Mail delivery is attempted to mail.example.com and mail2.example.com (in any order), and if neither of those succeed, delivery to mail.backup.org is attempted.

### Setting TTLs

The time to live of the RR field is a 32 bit integer represented in units of seconds, and is primarily used by resolvers when they cache RRs. The TTL describes how long an RR can be cached before it should be discarded. The following three types of TTL are currently used in a zone file.

| Item    | Description                                                                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SOA     | The last field in the SOA is the negative caching TTL. This controls how long other servers will cache no-such-domain (NXDOMAIN) responses from you.<br><br>The maximum time for negative caching is 3 hours (3h). |
| \$TTL   | The \$TTL directive at the top of the zone file (before the SOA) gives a default TTL for every RR without a specific TTL set.                                                                                      |
| RR TTLs | Each RR can have a TTL as the second field in the RR, which controls how long other servers can cache it.                                                                                                          |

All these TTLs default to units of seconds, though units can be explicitly specified, for example, 1h30m.

### Inverse Mapping in IPv4

Reverse name resolution (that is, translation from IP address to name) is achieved by means of the *in-addr.arpa* domain and PTR records. Entries in the *in-addr.arpa* domain are made in least-to-most significant order, read left to right. This is the opposite order to the way IP addresses are usually written. Thus, a machine with an IP address of 10.1.2.3 would have a corresponding *in-addr.arpa* name of 3.2.1.10.in-addr.arpa. This name should have a PTR resource record whose data field is the name of the machine or, optionally, multiple PTR records if the machine has more than one name. For example, in the [ example.com ] domain:

| Item     | Description             |
|----------|-------------------------|
| \$ORIGIN | 2.1.10.in-addr.arpa     |
| 3        | IN PTR foo.example.com. |

**Note:** The **\$ORIGIN** lines in the examples are for providing context to the examples only-they do not necessarily appear in the actual usage. They are only used here to indicate that the example is relative to the listed origin.

### Other Zone File Directives

The Master File Format was initially defined in RFC 1035 and has subsequently been extended. While the Master File Format itself is class independent all records in a Master File must be of the same class.

Master File Directives include **\$ORIGIN**, **\$INCLUDE**, and **\$TTL**.

## The \$ORIGIN Directive

Syntax: **\$ORIGIN domain-name [ comment ]**

**\$ORIGIN** sets the domain name that is appended to any unqualified records. When a zone is first read in there is an implicit **\$ORIGIN < zone-name>**. The current **\$ORIGIN** is appended to the domain specified in the **\$ORIGIN** argument if it is not absolute.

```
$ORIGIN example.com.
WWW CNAME MAIN-SERVER
```

is equivalent to

```
WWW.EXAMPLE.COM. CNAME MAIN-SERVER.EXAMPLE.COM.
```

## The \$INCLUDE Directive

Syntax: **\$INCLUDE filename [ origin ] [ comment ]**

Read and process the file **filename** as if it were included into the file at this point. If **origin** is specified the file is processed with **\$ORIGIN** set to that value, otherwise the current **\$ORIGIN** is used.

The origin and the current domain name revert to the values they had prior to the **\$INCLUDE** once the file has been read.

**Note:** RFC 1035 specifies that the current origin should be restored after an **\$INCLUDE**, but it is silent on whether the current domain name should also be restored. BIND 9 restores both of them. This could be construed as a deviation from RFC 1035, a feature, or both.

## The \$TTL Directive

Syntax: **\$TTL default-ttl [ comment ]**

Set the default Time To Live (TTL) for subsequent records with undefined TTLs. Valid TTLs are of the range 0-2147483647 seconds.

**\$TTL** is defined in RFC 2308.

## BIND Master File Extension: the \$GENERATE Directive

Syntax: **\$GENERATE range lhs type rhs [ comment ]**

**\$GENERATE** is used to create a series of resource records that only differ from each other by an iterator. **\$GENERATE** can be used to easily generate the sets of records required to support sub /24 reverse delegations described in RFC 2317: Classless IN-ADDR.ARPA delegation.

```
$ORIGIN 0.0.192.IN-ADDR.ARPA.
$GENERATE 1-2 0 NS SERVER$.EXAMPLE.
$GENERATE 1-127 $ CNAME $.0
```

is equivalent to

```
0.0.0.192.IN-ADDR.ARPA NS SERVER1.EXAMPLE.
0.0.0.192.IN-ADDR.ARPA NS SERVER2.EXAMPLE.
1.0.0.192.IN-ADDR.ARPA CNAME 1.0.0.0.192.IN-ADDR.ARPA
2.0.0.192.IN-ADDR.ARPA CNAME 2.0.0.0.192.IN-ADDR.ARPA
...
127.0.0.192.IN-ADDR.ARPA CNAME 127.0.0.0.192.IN-ADDR.ARPA
.
```

| Item  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| range | This can be one of two forms: start-stop or start-stop/step. If the first form is used then step is set to 1. All of start, stop, and step must be positive.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| lhs   | lhs describes the owner name of the resource records to be created. Any single \$ symbols within the lhs side are replaced by the iterator value. To get a \$ in the output you need to escape the \$ using a backslash \, e.g. \\$\$. The \$ may optionally be followed by modifiers which change the offset from the iterator, field width, and base. Modifiers are introduced by a { immediately following the \$ as \${offset[,width[,base]}]. For example, \${-20,3,d} which subtracts 20 from the current value, prints the result as a decimal in a zero padded field of width 3. Available output forms are decimal (d), octal (o) and hexadecimal (x or X for uppercase). The default modifier is \${0,0,d}. If the lhs is not absolute, the current \$ORIGIN is appended to the name. |
|       | For compatibility with earlier versions, \$\$ is still recognised as indicating a literal \$ in the output.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| type  | At present the only supported types are PTR, CNAME, DNAME, A, AAAA, and NS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| rhs   | rhs is a domain name. It is processed similarly to lhs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The **\$GENERATE** directive is a BIND extension and not part of the standard zone file format.

## Files

| Item                          | Description                                 |
|-------------------------------|---------------------------------------------|
| /usr/samples/tcpip/named.conf | Contains the sample <b>named.conf</b> file. |

## ndpdh.cnf File Format for TCP/IP

### Purpose

Defines the configuration file locations for the **ndpd-host** daemon and the **autoconf6** command.

### Description

The /etc/ndpd/ndpdh.cnf file is the default configuration file for the **ndpd-host** daemon and the **autoconf6** command. If the **ndpd-host** daemon or the **autoconf6** command is started without specifying an alternate file, they will read this file for information about how to locate all of the necessary files for enabling the SEND mode.

**Prerequisite:** To enable the SEND mode, the **clic.rte** fileset and OpenSSL must be installed.

The format of the **ndpdh.cnf** file when configuring the **ndpd-host** daemon and the **autoconf6** command is shown as follows:

| Keywords        | Values        | Description                                                |
|-----------------|---------------|------------------------------------------------------------|
| cga-params-file | Any file name | Name of the Cryptographically Generated Address (CGA) file |
| anchor-file     | Any file name | Name of the trust anchor file                              |

## Files

| Item                              | Description                               |
|-----------------------------------|-------------------------------------------|
| /usr/samples/tcpip/send/ndpdh.cnf | Contains the sample <b>ndpdh.cnf</b> file |

## netcd.conf File Format for netcd

### Purpose

Defines parameters for the **netcd** daemon.

### Description

The **/etc/netcd.conf** file is the default configuration file for the **netcd** daemon. This file is part of TCP/IP in Network Support Facilities.

To change the **/etc/netcd.conf** file, run the **stopsrc -s netcd** command and then the **startsrc -s netcd** command. The **netcd.conf** file specifies the map resolvers that are cached, and supplies parameters to the **netcd** daemon.

A template of the **netcd.conf** file is provided in the **/usr/samples/tcpip** directory.

**Attention:** Further installations can overwrite the **/usr/samples/tcpip/netcd.conf** file. You can copy this file to another location and use it as a template to create your customized **netcd** configuration.

If you do not use any configuration files, the **netcd** daemon proceeds with the default values indicated later in this section.

There are 4 types of declarations (a declaration or statement being a line starting with one of the keywords followed by parameters):

- cache description declarations (keyword - **cache**)
- security declarations (keywords - **owner**, **group** and **home\_dir**)
- log file declarations (keywords - **log\_file**, **log\_rotate**, and **log\_size**)
- additional declarations to control the **netcd** daemon (keywords - **net\_scan\_frequency**, **local\_scan\_frequency**, and **socket\_queue\_size**)

### Syntax

The general syntax is a string of characters that follows one or more spaces or tabs that follow the keyword, as shown in the following example:

```
cache <space><space><tab><tab> dns <space><space> local <tab><tab> foo
```

The syntax for each individual keyword is described in the following sections.

#### Cache description declarations

##### Syntax

**cache** <type\_of\_cache> <type\_of\_map> <hash\_size> <cache\_ttl>

0 to n **cache** declarations describe what is cached. If no such line is specified, the default line is cache all all 128 60.

The *type\_of\_cache* parameter can have the following values:

- **local** - local resolver
- **dns** - DNS resolver
- **nis** - nis resolver
- **nisplus** - nisplus resolver
- **yp** - yellow pages services
- **ulm** - other resolvers that you are using on your machine (if any)
- **all** - **local**, **dns**, **nis**, **nisplus**, **ulm**, and **yp** for the *type\_of\_cache* parameter
- a ulm name - the name of a specific resolver other than **local**, **dns**, **nis**, and **nisplus** that you installed

Any string other than **local**, **dns**, **nis**, **nisplus**, **yp**, **ulm**, and **all** is taken as a ulm name. You can declare up to 16 ulms.

The *type\_of\_map* parameter can have the following values:

- **hosts** - hosts map type of the resolver
- **protocols** - protocols map type of the resolver
- **services** - services map type of the resolver
- **networks** - networks map type of the resolver
- **netgroup** - netgroup map type of the resolver
- **all** - all map types applicable for the *type\_of\_map* parameter that you specified
- a yp map name - the name of a yellow page service from the list passwdbyname, passwdbyuid, groupbyname, groupbygid, netidbyname, and passwd.adjunctbyname

The map types supported for **local**, **nis**, **nisplus** and **ulm** resolutions are **hosts**, **services**, **networks**, **protocols** and **netgroup**. For the **dns** cache, **hosts** is the only map supported.

The maps supported for **yp** are **passwdbyname**, **passwdbyuid**, **groupbyname**, **groupbygid**, **netidbyname**, and **passwd.adjunctbyname**.

The *hash\_size* parameter specifies the number of lines for the cache (a cache is a hash table). The default value is 128.

The *cache\_ttl* parameter specifies the length of time during which an entry is kept in the cache. Its unit is minute. The value of 0 is infinite; the default value is 60. The *cache\_ttl* parameter is not taken into account for local caches. For **dns**, it is not suggested to specify a non-null value, because if you specify a non-null value, it overwrites the DNS time-to-live (TTL) sent back when DNS finds the entry. Otherwise, each entry is kept in the cache for the duration of the TTL that the DNS specifies.

## Security declarations

The three following declarations allow the **netcd** daemon to run in the secure mode (for example, security against code execution because of stack overflow):

| Item                          | Description                                                                                                       |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>owner &lt;value&gt;</b>    | Specifies the owner of the <b>netcd</b> daemon during its execution. The default value is <b>root</b> .           |
| <b>group &lt;value&gt;</b>    | Specifies the group owner of the <b>netcd</b> daemon during its execution. The default value is <b>system</b> .   |
| <b>home_dir &lt;value&gt;</b> | Specifies the working directory for the <b>netcd</b> daemon during its execution. The default value is <b>/</b> . |

## Log file declarations

| Item                             | Description                                                                                                                                          |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>log_file &lt;file&gt;</b>     | Specifies the name of the log file for the <b>netcd</b> daemon. The default value is <b>/var/tmp/netcd.log</b> .                                     |
| <b>log_rotate &lt;number&gt;</b> | Specifies the number of rotations for the log file. The default is no rotation, which is specified by not including a <b>log_rotate</b> declaration. |
| <b>log_size &lt;number&gt;</b>   | Specifies the size of the log file, in case of rotation, in KB.                                                                                      |

## Additional declarations

| Item                                      | Description                                                                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>net_scan_frequency &lt;value&gt;</b>   | Specifies the scan frequency, in minutes, of the network cache for expired entries because of TTL. The default value is 1.                                                                                                                                    |
| <b>local_scan_frequency &lt;value&gt;</b> | Specifies the scan frequency, in minutes, of the local files for modified dates. When a local file (for example, <b>/etc/hosts</b> ) is detected as modified, the corresponding local cache is reloaded with the content of the file. The default value is 1. |
| <b>socket_queue_size &lt;value&gt;</b>    | Specifies the size of the message queue for the socket that the <b>netcd</b> daemon uses to communicate with the requesting applications. This value indicates how many waiting requests the <b>netcd</b> daemon will accept. The default value is 256.       |

## Examples

1. To cache only local host resolutions with a hash table of 1024 lines, use the following cache declaration:  

```
cache local hosts 1024
```
2. To cache all of the local resolutions with caches of 512 lines, use the following cache declaration:  

```
cache local all 512
```
3. For all protocol resolutions with a hash table of 600 lines and with an expiration of 1 day, use the following cache declaration:  

```
cache all protocols 600 1440
```
4. For a **david ulm** for all maps with a hash table of 128 lines and with an expiration of 1 hour by default, use the following cache declaration:  

```
cache david all 128
```

## .netrc File Format for TCP/IP

### Purpose

Specifies automatic login information for the **ftp** and **rexec** commands.

## Description

The `$HOME/.netrc` file contains information used by the automatic login feature of the `rexec` and `ftp` commands. It is a hidden file in a user's home directory and must be owned either by the user executing the command or by the root user. If the `.netrc` file contains a login password, the file's permissions must be set to 600 (read and write by owner only). This file is part of TCP/IP in Network Support Facilities.

**Note:** The `.netrc` file is not used by any programs when the `securetcpip` command is running on your system.

The `.netrc` can contain the following entries (separated by spaces, tabs, or new lines):

| Item                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>machine HostName</code>  | The <code>HostName</code> variable is the name of a remote host. This entry begins the definition of the automatic login process for the specified host. All following entries up to the next machine entry or the end of the file apply to that host.                                                                                                                                                                                                                                                                                                                            |
| <code>default</code>           | The <code>default</code> variable is the same as <code>machine</code> except that <code>default</code> matches any name. There can be only one <code>default</code> entry. It must be the last entry (after all machine entries); otherwise, entries that follow it will be ignored. This is normally used as:<br><code>default login anonymous password user@site</code><br>thereby giving the user automatic anonymous ftp login to machines not specified in the <code>.netrc</code> file. This can be overridden by using the <code>-n</code> flag to disable the auto-login. |
| <code>login UserName</code>    | The <code>UserName</code> variable is the full domain user name for use at the remote host. If this entry is found, the automatic login process initiates a login, using the specified name. If this entry is missing, the automatic login process is unsuccessful.                                                                                                                                                                                                                                                                                                               |
| <code>password Password</code> | The <code>Password</code> variable is the login password to be used. The automatic login process supplies this password to the remote server. A login password must be established at the remote host, and that password must be entered in the <code>.netrc</code> file. Otherwise the automatic login process is unsuccessful, and the user is prompted for the login password.<br><b>Note:</b> You cannot use a space when you enter the password.                                                                                                                             |
| <code>account Password</code>  | The <code>Password</code> variable is the account password to be used. If this entry is found and an account password is required at the remote host, the automatic login process supplies the password to the remote server. If the remote host requires an account password but this entry is missing, the automatic login process prompts for the account password.                                                                                                                                                                                                            |
| <code>macdef MacroName</code>  | The <code>MacroName</code> variable is the name of an <code>ftp</code> subcommand macro. The macro is defined to contain all of the following <code>ftp</code> subcommands up to the next blank line or the end of the file. If the macro is named <code>init</code> , the <code>ftp</code> command executes the macro upon successful completion of the automatic login process. The <code>rexec</code> command does not recognize a <code>macdef</code> entry.                                                                                                                  |

## Examples

The following is an example of an entry in a `.netrc` file:

```
machine host1.austin.century.com login fred password bluebonnet
```

## Files

| Item                                  | Description                     |
|---------------------------------------|---------------------------------|
| <code>/usr/samples/tcpip/netrc</code> | Sample <code>.netrc</code> file |

## **networks File Format for TCP/IP**

### **Purpose**

Contains network name information.

### **Description**

The **/etc/networks** file contains information about the known networks that comprise the DARPA Internet. Each network is represented by a single line in the **networks** file. The format for the entries in the **networks** file is:

*Name Number Aliases*

The fields are described as follows:

| <b>Item</b>    | <b>Description</b>                                   |
|----------------|------------------------------------------------------|
| <i>Name</i>    | Specifies an official network name.                  |
| <i>Number</i>  | Specifies a network number.                          |
| <i>Aliases</i> | Specifies any unofficial names used for the network. |

Items on a line are separated by one or more spaces or tab characters. Comments begin with a # (pound sign). Routines that search the **networks** file do not interpret characters from the beginning of a comment to the end of that line. Network numbers are specified in dotted-decimal notation. A network name can contain any printable character except a field delimiter, new-line character, or comment character.

The **networks** file is normally created from the official network database maintained at the Network Information Center (NIC). The file can be modified locally to include unofficial aliases or unknown networks. This file is part of TCP/IP in Network Support Facilities.

### **Files**

| <b>Item</b>                        | <b>Description</b>                                                                  |
|------------------------------------|-------------------------------------------------------------------------------------|
| <b>/usr/samples/tcpip/networks</b> | Contains a sample <b>networks</b> file, which also contains directions for its use. |

routed command  
getnetent subroutine  
TCP/IP name resolution

## **nroff or troff Input File Format**

### **Purpose**

Specifies input file format for the **nroff** and **troff** commands.

### **Description**

The **nroff** and **troff** commands format text for printing by interspersing the text with control sequences. Control sequences are either control line requests or escape requests that control text processing by the printing device.

Control lines begin with a control character followed by a one- or two-character name that specifies a basic request or a user-defined macro. Default control characters are the . (dot) or the ' (apostrophe). The ' (apostrophe) control character suppresses the **nroff** or **troff** command break function, which is caused by some requests. This break function forces output of a partially filled line. To separate the control character

from the request or macro, use white space created with either a tab or the space bar. The **nroff** and **troff** commands ignore control lines with unrecognized names.

Escape requests can be inserted anywhere in the input text by means of an escape character. The \ (backslash) character is the default escape character. For example, the escape request \nr causes the contents of the number register, r, to be read.

**Note:** If text must begin a line with a . (dot), a zero-width character sequence (\&) must precede the control character. This is true even if the control character is preceded by an escape request. The zero-width character prevents the command from interpreting the text as a control character. See the example for an illustration of the use of a zero-width character.

## Examples

To print the words .dean, enter:

```
\fB\&.dean
```

If you neglected to add the \&, the formatter would read the statement as the macro request:

```
.de an
```

### Related information:

**nroff** command

**troff** command

## nterm File Format

### Purpose

Describes terminal driving tables for the **nroff** command.

### Description

The **nroff** command uses driving tables to customize its output for various types of output devices such as printing terminals, special word-processing terminals (such as Diablo, Qume, or NEC Spinwriter mechanisms), or special output-filter programs. These driving tables are written as ASCII files and are installed in the **/usr/share/lib/nterm/tab.Name** file, where the *Name* variable is the name for a terminal type.

The first line of a driving table should contain the name of the terminal, which is simply a string with no imbedded white space (any combination of spaces, tabs, and newline characters). The next part of the driver table is structured as follows:

- **bset** [*Integer*]
- **breset** [*Integer*]
- **hor** [*Integer*]
- **vert** [*Integer*]
- **newline** [*Integer*]
- **char** [*Integer*]
- **em** [*Integer*]
- **halfline** [*Integer*]
- **adj** [*Integer*]
- **twinit** [*Character String*]
- **twrest** [*Character String*]
- **twnl** [*Character String*]

- **hlr** [Character String]
- **hlf** [Character String]
- **flr** [Character String]
- **bdon** [Character String]
- **bdooff** [Character String]
- **iton** [Character String]
- **itoff** [Character String]
- **ploton** [Character String]
- **plotoff** [Character String]
- **up** [Character String]
- **down** [Character String]
- **right** [Character String]
- **left** [Character String]
- **codeset** [Character String]

The meanings of these fields are as follows:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bset</b>     | Specifies bits to set in the <code>c_oflag</code> field of the <b>termio</b> structure before output.                                                                                                                                                                                                                                                                                                                           |
| <b>breset</b>   | Specifies bits to reset in the <code>c_oflag</code> field of the <b>termio</b> structure before output.                                                                                                                                                                                                                                                                                                                         |
| <b>hor</b>      | Specifies horizontal resolution in units of 1/240 of an inch.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>vert</b>     | Defines vertical resolution in units of 1/240 of an inch.                                                                                                                                                                                                                                                                                                                                                                       |
| <b>newline</b>  | Defines space moved by a new-line (linefeed) character in units of 1/240 of an inch.                                                                                                                                                                                                                                                                                                                                            |
| <b>char</b>     | Defines a quantum of character sizes, in units of 1/240 of an inch (that is, a character is a multiple of <b>char</b> units wide).                                                                                                                                                                                                                                                                                              |
| <b>em</b>       | Defines the size of an em space in units of 1/240 of an inch.                                                                                                                                                                                                                                                                                                                                                                   |
| <b>halfline</b> | Defines the amount of space moved by a half-linefeed (or half-reverse-linefeed) character in units of 1/240 of an inch.                                                                                                                                                                                                                                                                                                         |
| <b>adj</b>      | Defines a quantum of white space, in 1/240 of an inch; that is, white spaces are a multiple of <b>adj</b> units wide.<br><b>Note:</b> If this is less than the size of the space character, the <b>nroff</b> command outputs fractional spaces using plot mode. Also, if the <b>-e</b> switch to the <b>nroff</b> command is used, the <b>adj</b> variable is set equal to the <b>hor</b> variable by the <b>nroff</b> command. |
| <b>twinit</b>   | Specifies a sequence of characters used to initialize the terminal in a mode suitable for the <b>nroff</b> command.                                                                                                                                                                                                                                                                                                             |
| <b>twrest</b>   | Specifies a sequence of characters used to restore the terminal to normal mode.                                                                                                                                                                                                                                                                                                                                                 |
| <b>twnl</b>     | Specifies a sequence of characters used to move down one line.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>hlr</b>      | Specifies a sequence of characters used to move up one-half line.                                                                                                                                                                                                                                                                                                                                                               |
| <b>hlf</b>      | Specifies a sequence of characters used to move down one-half line.                                                                                                                                                                                                                                                                                                                                                             |
| <b>flr</b>      | Specifies a sequence of characters used to move up one line.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>bdon</b>     | Specifies a sequence of characters used to turn on hardware boldface mode, if any.                                                                                                                                                                                                                                                                                                                                              |
| <b>bdooff</b>   | Specifies a sequence of characters used to turn off hardware boldface mode, if any.                                                                                                                                                                                                                                                                                                                                             |
| <b>iton</b>     | Specifies a sequence of characters used to turn on hardware italics mode, if any.                                                                                                                                                                                                                                                                                                                                               |
| <b>itoff</b>    | Specifies a sequence of characters used to turn off hardware italics mode, if any.                                                                                                                                                                                                                                                                                                                                              |
| <b>ploton</b>   | Specifies a sequence of characters used to turn on hardware plot mode (for Diablo-type mechanisms), if any.                                                                                                                                                                                                                                                                                                                     |
| <b>plotoff</b>  | Specifies a sequence of characters used to turn off hardware plot mode (for Diablo-type mechanisms), if any.                                                                                                                                                                                                                                                                                                                    |
| <b>up</b>       | Specifies a sequence of characters used to move up one resolution unit ( <b>vert</b> ) in plot mode, if any.                                                                                                                                                                                                                                                                                                                    |
| <b>down</b>     | Specifies a sequence of characters used to move down one resolution unit ( <b>vert</b> ) in plot mode, if any.                                                                                                                                                                                                                                                                                                                  |
| <b>right</b>    | Specifies a sequence of characters used to move right one resolution unit ( <b>hor</b> ) in plot mode, if any.                                                                                                                                                                                                                                                                                                                  |
| <b>left</b>     | Specifies a sequence of characters used to move left one resolution unit ( <b>hor</b> ) in plot mode, if any.                                                                                                                                                                                                                                                                                                                   |

| Item                              | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>codeset</b> <i>CodeSetName</i> | Specifies the code set for the particular output device. <i>CodeSetName</i> is any valid name for use with the <b>iconv</b> command. The code set defines character entries within the font description file for the character set section. The code set field is optional. If used, the code set field must follow the "left" field and precede the character set section, if provided. The default is <b>IBM-850</b> . |

The **nroff** command uses the specified *CodeSetName* and the code set implied by the current locale to determine if code set conversions are necessary for the input characters. The **iconv** function is used to perform the code set conversion if necessary.

This part of the driving table is fixed-format; you cannot change the order of entries. Entries should be on separate lines each containing two fields (no comments allowed) separated by white space; for example:

```
bset 0
breset 0
Hor 24
```

Follow this first part of the driving table with a line containing only the word **charset**, and then specify a table of special characters that you want to include. That is, specify all the non-ASCII characters that the **nroff** command knows by 2-character names, such as \(hy. If the **nroff** command does not find the word **charset** where it expects, it terminates processing with an error message.

Each definition after **charset** occupies one line and has the following format:

```
chname width output
```

The **chname** field is the (2-letter) name of the special character, the **width** field is its width in ems, and the **output** field is the string of characters and escape sequences to send to the terminal to produce the special character.

### International Character Support

For fonts for large character sets in which most characters are the same width, as in Japanese, Chinese, and Korean, prototype characters are provided for the character set section of the **nterm** table. These prototype characters specify the width of characters of varying byte lengths. The code field for prototype character entries must contain a single ? (question mark). The prototype character entries apply to all characters not explicitly defined on their own in the character set section. It is assumed the output device code for characters handled via prototype characters is the same as the input code for characters (with possible codeset conversions). The following are the prototype character definitions:

```
X1 Width ? Represents the width of all one-byte characters not defined elsewhere.
X2 Width ? Represents the width of all two-byte characters not defined elsewhere.
X3 Width ? Represents the width of all three-byte characters not defined elsewhere.
X4 Width ? Represents the width of all four-byte characters not defined elsewhere.
```

If any field in the **charset** part of the driving table does not pertain to the output device, you can give that particular sequence as a null string or leave out the entry. Special characters that do not have a definition in this file are ignored on output by the **nroff** command.

You can put the **charset** definitions in any order, so it is possible to speed up the **nroff** command by putting the most used characters first. For example:

```
charset
em 1-
hy 1-
\1-
bu 1 +\bo
```

The best way to create a terminal table for a new device is to take an existing terminal table and edit it to suit your needs. Once you create such a file, put it in the `/usr/share/lib/nterm` directory. Then, give it the name `tab.xyz`, where the `xyz` variable is the name of the terminal and also the name that you pass the `nroff` command by way of the `-T` flag. For example:

```
nroff -Txyz
```

## Files

| Item                                       | Description              |
|--------------------------------------------|--------------------------|
| <code>/usr/share/lib/nterm/tab.Name</code> | Contains terminal files. |

## Permissions File Format for BNU

### Purpose

Specifies BNU permissions for remote systems that call or are called by the local system.

### Description

The `/etc/uucp/Permissions` file specifies access for remote systems that use the Basic Networking Utilities (BNU) program to communicate with the local system. The **Permissions** file contains an entry for each system the local system contacts using BNU. These entries correspond to entries in the `/etc/uucp/Systems` file or other systems files listed in the `/etc/uucp/Sysfiles` file with the same format. The **Permissions** file also contains an entry for each login ID that remote systems are permitted to use when using BNU to log into the local system.

Entries in the **Permissions** file specify:

- The login ID for a remote system
- The circumstances under which a remote system is allowed to send files to and receive files from the local system
- The commands a remote system is permitted to execute on the local system.

The access permissions set in a **Permissions** file affect remote systems as a whole. They do *not* pertain to individual users who work on those remote systems. Permissions limiting `uucico` and `uuxqt` daemon activities restrict the BNU access to a local system by *all* users on a specified remote system. The default permissions for sending and receiving files and executing commands are very restrictive. However, the file also provides options that enable you to change these defaults if you want to allow remote systems to have less restricted access to the local system.

Each entry in a **Permissions** file is a logical line. If an entry is too long to fit on the screen, make the last character in that physical line a \ (backslash), which indicates continuation, and then type the remainder of the entry on the next physical line.

Each logical line contains a required entry specifying a login ID (LOGNAME entry) or the name of a remote system (MACHINE entry), followed by optional option/value pairs separated by either spaces or tabs. Both the LOGNAME and MACHINE entries and the option/value pairs are composed of name/value pairs. Name/value pairs consist of the name of the entry or option followed by an = (equal sign) and the value of the entry or option, with no spaces allowed within the pair.

The **Permissions** file can also contain comment lines and blank lines. Comment lines begin with a # (pound sign) and occupy the entire physical line. Blank lines are ignored.

**Note:**

1. Access permissions set in the **Permissions** file affect all BNU communications, including those made through the mail facility or over a TCP/IP connection. Entries in a **Permissions** file do *not* affect a remote-system user with a valid login on a specified local system. Remote login commands (such as **cu**, **ct**, **tn**, or **tip**) connect to and log in on a system regardless of the restrictions set up in the **localPermissions** file. A user with a valid login ID is subject only to the permission codes established for that user's user ID (UID) and group ID (GID).
2. Examples of using the **Permissions** file are provided. The examples include issuing default or restricted access to remote systems and combining LOGNAME and MACHINE entries.

## LOGNAME and MACHINE Entries

The **Permissions** file contains two types of required entries:

| Item    | Description                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------------------|
| LOGNAME | Specifies the login IDs and access permissions for remote systems that are allowed to contact the local system. |
| MACHINE | Specifies the names and access permissions for the remote systems that the local system can contact.            |

Both LOGNAME and MACHINE entries specify *what the remote system can do on the local system*. LOGNAME entries take effect when a remote system contacts the local system. MACHINE entries take effect when the local system contacts a remote system. The permissions given to the remote system in the two types of entries can be the same or different.

For example, if remote system **hera** contacts local system **zeus** and logs in as **uhera**, the LOGNAME=**uhera** entry in the **Permissions** file on **zeus** controls what actions system **hera** can take on system **zeus**. If system **zeus** contacts system **hera**, the MACHINE=**hera** entry in the **Permissions** file on **zeus** controls what actions system **hera** can take on system **zeus**.

The most restrictive LOGNAME and MACHINE entry is an entry without any option/value pairs, which means that the remote system's access to the local system is defined by the default permissions. To override these defaults, include option/value pairs in the entry. The available options are:

- REQUEST
- SENDFILES
- READ,WRITE
- NOREAD,NOWRITE
- COMMANDS
- VALIDATE
- CALLBACK

These options allow different remote systems different types of access to the local system when using the BNU file transport and command execution programs. A LOGNAME and a MACHINE entry can be combined into a single entry when both include the same options.

### LOGNAME Entry

A LOGNAME entry specifies one or more login IDs for remote systems permitted to log into the local system to conduct **uucico** and **uuxqt** daemon transactions, plus the access permissions for those remote systems. The login ID can be any valid login name. The LOGNAME entry specifies permissions for the remote system when it contacts the local system. The format of a LOGNAME entry is:

**LOGNAME**=*LoginID*[:*LoginID* . . .] [*Option=Value* . . .]

Remote systems log in with one of the IDs listed in the *LoginID* list. While logged in with that ID, the remote system has the permissions specified in the *Option=Value* list. The remote system that is calling must be listed in the **/etc/uucp/Systems** file or an alternative **uucico** service systems file specified in **/etc/uucp/Sysfiles** on the local system.

To specify more than one login ID with the same option/value pairs, list them in the same LOGNAME entry, separated by colons but without spaces. To specify multiple login IDs with different option/value pairs, list them in separate LOGNAME entries.

The most restrictive LOGNAME entry is an entry without any option/value pairs. The remote system's access to the local system is then defined by these default permissions:

- The remote system cannot ask to receive any queued files from the local system.
- The local system cannot send queued work to the calling remote system when the remote system has completed its current operations. Instead, the queued work can be sent only when the local system contacts the remote system.
- The remote system cannot send files to (write) or transfer files from (read) any location except the BNU public directory (*/var/spool/uucppublic/SystemName*) on the local system.
- Users on the remote system can execute only the default commands on the local system. (The default command set includes only the **rmail** command, which users implicitly execute by issuing the **mail** command.)

To override these defaults, include option/value pairs in the LOGNAME entry.

**Note:** A login ID can appear in only one LOGNAME entry. If there is a single entry for a login ID, that entry alone is sufficient for all remote systems using that login ID.

**Attention:** Allowing remote systems to log in to the local system with the **uucp** login ID seriously jeopardizes the security of your system. Remote systems logged in with the **uucp** ID can display and possibly modify (depending on the other permissions specified in the LOGNAME entry) the local **Systems** and **Permissions** files. It is strongly recommended that you create other BNU login IDs for remote systems and reserve the **uucp** login ID for the person responsible for administering BNU on the local system. Each remote system that contacts the local system should have a unique login ID with a unique UID.

## MACHINE Entry

The **Permissions** file contains a MACHINE entry for each remote system the local system is permitted to contact. The access permissions specified in the MACHINE entry affect the remote system's access to the local system when the local system contacts the remote system. Following is the format of a MACHINE entry:

**MACHINE**=*SystemName*[:*SystemName* . . .] [*Option=Value* . . .]

OR

**MACHINE=OTHER** [*Option=Value* . . .]

The most restrictive type of MACHINE entry, which uses the default permissions, is:

**MACHINE**=*SystemName*[:*SystemName* . . .]

The system names are separated by a colon. The entry includes no spaces or tab characters. There are no option/value pairs, indicating that remote system access to the local system is defined by the following default permissions:

- The remote system cannot ask to receive any local system files queued to run on the calling remote system.
- The remote system cannot access (read) any files except those in the public directory on the local system.
- The remote system can send (write) files only to the local public directory.
- The remote system can execute only those commands in the default command set on the local system.

To override these defaults, include option/value pairs in the LOGNAME entry.

The *SystemName* list in a MACHINE entry may include a number of different remote systems. A MACHINE entry can also be:

**MACHINE=OTHER [Option=Value . . . ]**

where the word OTHER represents a system name. This sets up access permissions for remote systems not specified in the existing MACHINE entries in a **Permissions** file. The **MACHINE=OTHER** entry is useful in these circumstances:

- When your installation includes a large number of remote systems that the local system regularly contacts for **uucico** and **uuxqt** daemon transactions
- When it is occasionally necessary to change the default command set specified in the COMMANDS option in the MACHINE entry.

Rather than create separate MACHINE entries for each of a large group of remote systems, set up one **MACHINE=OTHER** entry that includes the appropriate commands specified in a COMMANDS option entry. Then, when it becomes necessary to change the default command set, change the list of commands in only one entry rather than in numerous entries. Usually, a **MACHINE=OTHER** entry also specifies more restrictive option values for the unidentified remote systems.

**Note:** The local system cannot call any remote system that is not listed by name in a MACHINE entry, unless there is a **MACHINE=OTHER** entry in the **Permissions** file on the local system.

## Option/Value Pairs

Option/value pairs can be used with the LOGNAME and MACHINE entries. The default permissions are restrictive, but can be changed with one or more of the option/value pairs. These options allow different remote systems different types of access to the local system when using the BNU file transport and command execution programs.

### CALLBACK Option

The CALLBACK option, included in LOGNAME entries, specifies that no file transfer transactions will occur until the local system contacts the targeted remote system. The format of the CALLBACK option is either:

**CALLBACK=no**

OR

**CALLBACK=yes**

**Note:** If two systems both include the **CALLBACK=yes** option in their respective **Permissions** files, they cannot communicate with each other using BNU.

The default value, **CALLBACK=no**, specifies that the remote system may contact the local system and begin transferring files without the local system initiating the operations.

For tighter security, use the **CALLBACK=yes** option to specify that the local system must contact the remote system before the remote system may transfer any files to the local system.

If you include the **CALLBACK=yes** option in the LOGNAME entry, you must also have a MACHINE entry for that system so that your system can call it back. You can have a **MACHINE=OTHER** entry to allow your system to call any remote system, including the one for which the **CALLBACK=yes** option is specified.

The default value, **CALLBACK=no**, is generally sufficient for most sites.

### **COMMANDS Option**

The COMMANDS option, included only in a MACHINE entry, specifies the commands that the remote systems listed in that MACHINE entry can execute on the local system. The format of the COMMANDS option is either:

**COMMANDS=CommandName[:CommandName . . .]**

OR

**COMMANDS=ALL**

The default is **COMMANDS=rmail:uucp**. Under the default, remote systems can run only the **rmail** and **uucp** commands on the local system. (Users enter the **mail** command, which then calls the **rmail** command.)

The commands listed in the COMMANDS option override the default. You can also specify path names to those locations on the local system where commands issued by users on remote systems are stored. Specifying path names is useful when the default path of the **uuxqt** daemon does not include the directory where a command resides.

**Note:** The default path of the **uuxqt** daemon includes only the **/usr/bin** directory.

To allow a certain remote system to execute all available commands on the local system, use the **COMMANDS=ALL** format. This specifies that the command set available to the designated remote system includes all commands available to users on the local system.

**Note:** The COMMANDS option can jeopardize the security of your system. Use it with extreme care.

### **NOREAD and NOWRITE Options**

The NOREAD and NOWRITE options, used in both LOGNAME and MACHINE entries, delineate exceptions to the READ and WRITE options by explicitly forbidding access by the remote system to directories and files on the local system.

The formats of these options follow:

**NOREAD=PathName[:PathName . . .]**

**NOWRITE=PathName[:PathName . . .]**

**Note:** The specifications you enter with the READ, WRITE, NOREAD, and NOWRITE options affect the security of your local system in terms of BNU transactions.

### **READ and WRITE Options**

The READ and WRITE options, used in both LOGNAME and MACHINE entries, specify the path names of directories that the **uucico** daemon can access when transferring files to or from the local system. You can specify more than one path for **uucico** daemon activities.

The default location for both the READ and WRITE options is the **/var/spool/uucppublic** directory (the BNU public directory) on the local system. The formats for these options follow:

**READ=***PathName[: PathName . . .]*

**WRITE=***PathName[: PathName . . .]*

The source file, destination file, or directory must be readable or writable for the other group for the BNU program to access it. Set these permissions with the **chmod** command. A user without root user authority can take away permissions granted by the READ and WRITE options, but that user cannot grant permissions that are denied by these options.

If the READ and WRITE options are not present in the **Permissions** file, the BNU program transfers files only to the **/var/spool/uucppublic** directory. However, if you specify path names in these options, enter the path name for every source and destination, including the **/var/spool/uucppublic** directory if the remote system is to be permitted access to it.

**Attention:** Specifications with the READ, WRITE, NOREAD, and NOWRITE options affect the security of your local system in terms of BNU transactions. The subdirectories of directories specified in the READ and WRITE options can also be accessed by the remote system unless these subdirectories are forbidden with the NOREAD or NOWRITE options.

### **REQUEST Option**

The REQUEST option, used in both LOGNAME and MACHINE entries, enables a remote system to ask to receive any queued files containing work that users on the local system have requested to be executed on that remote system. The default is not to allow such requests.

When a remote system contacts the local system to transfer files or execute commands, the remote system may also request permission to receive any files queued on the local system for transfer to or execution on that remote system. This format of the REQUEST option permits such requests:

**REQUEST=yes**

The default, **REQUEST=no**, does not have to be entered. This specifies that the remote system cannot ask to receive any work queued for it on the local system. The local system must contact the remote system before transmitting files and execute commands queued on the local system to the remote system.

Use the **REQUEST=yes** option in both LOGNAME and MACHINE entries to allow remote-system users to transfer files to and execute commands on a local system on demand. Restrict access with the **REQUEST=no** option so that the local system retains control of file transfers and command executions initiated by remote systems.

**Note:** Entries in the **Permissions** file affect only BNU transactions. They do not affect remote-system users with valid logins on a local system.

### **SENDFILES Option**

The default allows the local system to transfer queued work to the remote system only when the local system contacts the remote system. However, when a remote system finishes transferring files to or executing commands on a local system, that local system may try to send queued work to the calling remote system immediately. To enable an immediate transfer, use the following SENDFILES option:

### **SENDFILES=yes**

The **SENDFILES=yes** option allows the transfer of queued work from the local to the remote system once the remote system has completed its operations. The default value, **SENDFILES=call**, specifies that local files queued to run on the remote system are sent only when the local system contacts the remote system.

#### **Note:**

1. The SENDFILES option is ignored when it is included in a MACHINE entry.
2. Entries in the **Permissions** file affect only BNU transactions. They do not affect remote-system users with valid logins on a local system.

### **VALIDATE Option**

The VALIDATE option provides more security when including commands in the default command set that could cause damage when executed by a remote system on a local system. Use this option, specified only in a MACHINE entry, in conjunction with a COMMANDS option. The format of the VALIDATE option is:

**VALIDATE=***LoginName[: LoginName . . .]*

The VALIDATE option verifies the identity of the calling remote system. Including this option in a MACHINE entry means that the calling remote system must have a unique login ID and password for file transfers and command executions.

**Note:** This option is meaningful only when the login ID and password are protected. Giving a remote system a special login and password that provide unlimited file access and remote command-execution ability is equivalent to giving any user on that remote system a normal login and password on the local system, unless the special login and password are well-protected.

The VALIDATE option links a MACHINE entry, which includes a specified COMMANDS option, to a LOGNAME entry associated with a privileged login. The **uuxqt** daemon, which executes commands on the local system on behalf of users on a remote system, is not running while the remote system is logged in. Therefore, the **uuxqt** daemon does not know which remote system sent the execution request.

Each remote system permitted to log in to a local system has its own spooling directory on that local system. Only the BNU file transport and command execution programs are allowed to write to these directories. For example, when the **uucico** daemon transfers execution files from the remote system *hera* to the local system *zeus*, it places these files in the */var/spool/uucppublic/hera* directory on system *zeus*.

When the **uuxqt** daemon attempts to execute the specified commands, it determines the name of the calling remote system (*hera*) from the path name of the remote-system spooling directory (*/var/spool/uucppublic/hera*). The daemon then checks for that name in a MACHINE entry in the **Permissions** file. The daemon also checks for the commands specified in the COMMANDS option in a MACHINE entry to determine whether the requested command can be executed on the local system.

## **Security**

Access Control: Only a user with root authority can edit the **Permissions** file.

## Examples

The following are examples of using the **Permissions** file.

### Providing Default Access to Remote Systems

1. To provide the default permissions to any system logging in as uucp1, enter:  
`LOGNAME=uucp1`
2. To provide the default permissions to systems venus, apollo, and athena when called by the local system, enter:  
`MACHINE=venus:apollo:athena`

### Providing Less Restricted Access to Remote Systems

1. The following LOGNAME entry allows remote system merlin to read and write to more directories than just the spool directory:

```
LOGNAME=umerlin READ=/ NOREAD=/etc:/usr/sbin/uucp
WRITE=/home/merlin:/var/spool/uucppublic
```

A system logging in as user umerlin can read all directories except the `/usr/sbin/uucp` and `/etc` directories, but can write only to the `/home/merlin` and public directories. Because the login name umerlin has access to more information than is standard, BNU validates the system before allowing merlin to log in.

2. The following example allows remote system hera unrestricted access to system zeus, and shows the relationship between the LOGNAME and MACHINE entries:

```
LOGNAME=uhera REQUEST=yes SENDFILES=yes READ
=/ WRITE=/MACHINE=hera VALIDATE=uhera REQUEST=yes \COMMANDS=ALL READ=/ WRITE=/
```

The remote system hera may engage in the following **uucico** and **uuxqt** transactions with system zeus:

- System hera may request that files be sent from system zeus, regardless of which system placed the call (`REQUEST=yes` appears in both entries);
- System zeus may send files to system hera when system hera contacts system zeus (`SENDFILES=yes` in the LOGNAME entry);
- System hera may execute all available commands on system zeus (`COMMANDS=ALL` in the MACHINE entry);
- System hera may read from and write to all directories and files under the **root** directory on system zeus, regardless of which system placed the call (`READ=/` `WRITE=/` in both entries).

Because the entries provide system hera with relatively unrestricted access to system zeus, BNU validates the log name before permitting system hera to log in.

**Note:** This entry allows unrestricted access to the local system by the remote system listed in the MACHINE entry. This entry can jeopardize the security of your system.

### Combining LOGNAME and MACHINE Entries

1. Following are LOGNAME and MACHINE entries for system hera:

```
LOGNAME=uhera REQUEST=yes SENDFILES=yes
MACHINE=hera VALIDATE=uhera REQUEST=yes COMMANDS=rmail:news:uucp
```

Since they have the same permissions and apply to the same remote system, these entries can be combined as:

```
LOGNAME=uhera SENDFILES=yes REQUEST=yes \
MACHINE=hera VALIDATE=uhera COMMANDS=rmail:news:uucp
```

2. LOGNAME and MACHINE entries used for more than one remote system can be combined if they have the same permissions. For example:

```
LOGNAME=uucp1 REQUEST=yes SENDFILES=yes
MACHINE=zeus:apollo:merlin REQUEST=yes COMMANDS=rmail:uucp
```

can be combined as:

```
LOGNAME=uucp1 REQUEST=yes SENDFILES=yes \MACHINE=zeus:apollo:
merlin COMMANDS=rmail:uucp
```

Either form of the entries allows systems zeus, apollo, and merlin the same permissions. They can:

- Log into the local system as uucp1.
- Execute the **rmail** and **uucp** commands.
- Request files from the local system, regardless of which system placed the call.

### Allowing Access to Unnamed Systems

To allow your system to call systems that are not specified by name in a MACHINE entry, use a MACHINE=OTHER entry as follows:

```
MACHINE=OTHER COMMANDS=rmail
```

This entry allows your system to call any machine. The machine called will be able to request execution of the **rmail** command. Otherwise, the default permissions apply.

### Permissions File Entries for Three Systems

The following examples show the **Permissions** files for three connected systems:

On system venus:

```
LOGNAME=uhera MACHINE=hera \
READ=/ WRITE=/ COMMANDS=ALL \
NOREAD=/usr/secure:/etc/uucp \
NOWRITE=/usr/secure:/etc/uucp
SENDFILES=yes REQUEST=yes VALIDATE=hera
```

On system hera:

```
LOGNAME=uvenus MACHINE=venus \
READ=/ WRITE=/ COMMANDS=rmail:who:lp:uucp \
SENDFILES=yes REQUEST=yes

LOGNAME=uucp1 MACHINE=OTHER \
REQUEST=yes SENDFILES=yes
```

On system apollo:

```
LOGNAME=uhera MACHINE=hera \
READ=/var/spool/uucppublic:/home/hera \
REQUEST=no SENDFILES=call
```

Given these permissions:

- System hera logs into system venus as uhera. It can request or send files regardless of who initiated the call and can read or write to all directories except **/usr/secure** and **/usr/sbin/uucp**. It can execute any command. However, before system venus allows any system to log in as uhera, it checks to make sure that system is hera.
- System venus logs into system hera as uvenus. After it logs in, it can read or write to all directories on system hera and can request or send commands regardless of who initiated the call. It can execute the **rmail**, **who**, **lp**, and **uucp** commands only.
- System hera logs into system apollo as uhera. After it logs in, it can send files, but requests to receive files will be denied. It can read and write only from the public directory and the **/home/hera** directory, and can execute only the default list of commands.

- System apollo logs into system hera as uucp1, since it does not have a unique login ID on system hera. It can request and send files, regardless of who initiated the call. It can read and write only from the public directory (the default) and execute only the default list of commands.

**Note:** The uucp1 login ID defined on system hera can be used by any remote system, not just by system apollo. In addition, the presence of the MACHINE=OTHER entry allows system hera to call machines not specified elsewhere in the **Permissions** file. If system hera calls an unknown machine, the permissions in the MACHINE=OTHER entry take effect.

## Files

| Item                            | Description                                                          |
|---------------------------------|----------------------------------------------------------------------|
| /etc/uucp/Permissions file      | Describes access permissions for remote systems.                     |
| /etc/uucp/Systems file          | Describes accessible remote systems.                                 |
| /etc/uucp/Sysfiles file         | Specifies possible alternative files for the /etc/uucp/Systems file. |
| /var/spool/uucppublic directory | Contains files that have been transferred.                           |

## phones File Format for tip

### Purpose

Describes connections used by the **tip** command to contact remote systems.

### Description

The **/etc/phones-file** file lists the remote systems that can be contacted using the **tip** command, along with the telephone numbers used to contact those systems.

A sample **phones-file** file for the **tip** command is included with the operating system. The sample file is named **/usr/lib/phones-file**. A user with root user authority can copy the sample file to the **/etc/phones** file and modify it to suit the needs of a particular site.

Any **tip** user can create an individual phones file in the format of the **phones-file** file. The individual phones file can be named with any operating system file name and placed in any directory to which the user has access. To instruct the **tip** command to use the new file, either set the **tip** command **phones** variable or set an environment variable named **PHONES**.

Systems listed in the **phones** file must also be described in the **/etc/remote-file** file, in the file specified by the **REMOTE** environment variable, or in the file specified by the **tip** command **remote** variable.

### Format of Entries

The format of an entry in the **phones** file is:

*SystemName*      *PhoneNumber*

The *SystemName* field and the *PhoneNumber* field must be separated by at least one space. More than one space can be used to improve readability.

| Item               | Description                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <i>SystemName</i>  | Specifies the name of the remote system to be contacted.                                                                                |
| <i>PhoneNumber</i> | Specifies the telephone number, including line access codes, to be used to reach the remote system. Dashes may be used for readability. |

If more than one phone number can be used to reach a certain system, make multiple entries for that system, placing each entry on a separate line.

Any line beginning with a # (pound sign) is interpreted as a comment.

## Examples

1. To list phone numbers in a **phones** file, make entries similar to the following:

```
hera 1237654
zeus 9-512-345-9999
```

System hera is contacted using the telephone number 123-7654. To contact system zeus, a line-access code of 9 is followed by the telephone number 512-345-9999.

2. To define more than one phone number for the same system, make multiple entries for that system, as follows:

```
decvax 9-915-987-1111
decvax 9-915-987-2222
```

If the **tip** command cannot reach the decvax system using the first phone number, it attempts to contact the system using the second phone number.

## Files

| Item                        | Description                                                                  |
|-----------------------------|------------------------------------------------------------------------------|

## Poll File Format for BNU

### Purpose

Specifies when the BNU program should poll remote systems.

### Description

The */etc/uucp/Poll* file specifies when the Basic Networking Utilities (BNU) program should poll (initiate automatic calls to) designated remote computers. This file is used in conjunction with the */var/spool/cron/crontabs/uucp* file, **uudemon.hour** command, and **uudemon.poll** command. Together, these files are responsible for initiating automatic calls to certain remote systems.

Each entry in the **Poll** file contains the name of the remote computer followed by a sequence of times when the BNU program should poll that system. Modify the times specified in the **Poll** file based on how the systems at your site are used. Specify times as digits between 0 and 23. The format of the entry is as follows:

```
SystemName Time [Time ...]
```

The fields in the **Poll** file entry must be separated by at least one space. More spaces can be used for readability. A tab character between the *SystemName* field and the first *Time* field is optional.

#### Note:

1. Only someone with root user authority can edit the **Poll** file, which is owned by the **uucp** program login ID.
2. Most versions of UUCP require a tab character between the *SystemName* field and the first *Time* field. In BNU, either a tab or spaces will work.

## Examples

Following is a standard entry in the **Poll** file:

```
hera <TAB> 0 4 8 12 16 20
```

This entry specifies that the local system will poll the remote system *hera* every 4 hours.

The tab character can be replaced by one or more spaces. Thus the preceding entry is equivalent to the following one:

```
hera 0 4 8 12 16 20
```

## Files

| Item                          | Description                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------|
| /etc/locks                    | Contains lock files that prevent multiple uses of devices and multiple calls to systems. |
| /var/spool/cron/crontabs/uucp | Schedules BNU jobs for the <b>cron</b> daemon.                                           |

## profile File Format

### Purpose

Sets the user environment at login time.

### Description

The **\$HOME/.profile** file contains commands that the system executes when you log in. The **.profile** also provides variable profile assignments that the system sets and exports into the environment. The **/etc/profile** file contains commands run by all users at login.

After the **login** program adds the **LOGNAME** (login name) and **HOME** (login directory) variables to the environment, the commands in the **\$HOME/.profile** file are executed, if the file is present. The **.profile** file contains the individual user profile that overrides the variables set in the **profile** file and customizes the user-environment profile variables set in the **/etc/profile** file. The **.profile** file is often used to set exported environment variables and terminal modes. The person who customizes the system can use the **mkuser** command to set default **.profile** files in each user home directory. Users can tailor their environment as desired by modifying their **.profile** file.

**Note:** The **\$HOME/.profile** file is used to set environments for the Bourne and Korn shells. An equivalent environment for the C shell is the **\$HOME/.cshrc** file.

## Examples

The following example is typical of an **/etc/profile** file:

```
#Set file creation mask unmask 022
#Tell me when new mail arrives
MAIL=/usr/mail/$LOGNAME
#Add my /bin directory to the shell
search sequence
PATH=/usr/bin:/usr/sbin:/etc::
#Set terminal type
TERM=1ft
#Make some environment variables global
export MAIL PATH TERM
```

## Files

## protocols File Format for TCP/IP

### Purpose

Defines the Internet protocols used on the local host.

### Description

The **/etc/protocols** file contains information about the known protocols used in the DARPA Internet. Each protocol is represented by a single line in the **protocols** file. Each entry corresponds to the form:

*Name Number Aliases*

The fields contain the following information:

| Item           | Description                                           |
|----------------|-------------------------------------------------------|
| <i>Name</i>    | Specifies an official Internet Protocol name.         |
| <i>Number</i>  | Specifies a protocol number.                          |
| <i>Aliases</i> | Specifies any unofficial names used for the protocol. |

Items on a line are separated by one or more spaces or tab characters. Comments begin with the # (pound sign), and routines that search the **protocols** file do not interpret characters from the beginning of a comment to the end of the line. A protocol name can contain any printable character except a field delimiter, new line character, or comment character.

The protocol and alias names are case sensitive.

The lines appear as follows:

```
ip 0 #dummy for IP
icmp 1 #control message protocol
#ggp 2 #gateway^2 (not normally used)
```

```

tcp 6 #tcp
#egp 8 #exterior gateway protocol
#pup 12 #pup
udp 17 #user datagram protocol

```

#### **Related information:**

TCP/IP protocols

## **queuedefs File Format**

### **Purpose**

Specifies the handling of **cron** daemon events.

### **Description**

The **/var/adm/cron/queuedefs** file defines how the system handles different **cron** daemon events types. The file specifies the maximum number of processes per event type to schedule at one time, the nice value of the event type, and how long to wait before retrying to execute a process. The following event types can be scheduled by the **cron** daemon:

- **at** command events
- **batch** command events
- **crontab** command events
- **sync** subroutine events
- **ksh** command events
- **csh** command events

This file is empty as shipped, but can be modified to change how the **cron** daemon handles each event type. Each entry in the **queuedefs** file is of the form:

*EventType.* [*Jobsj*] [*Nicen*] [*Waitw*]

The fields are described as follows:

| Item             | Description                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>EventType</b> | Specifies a character representing an event type. The following are valid values for the <b>EventType</b> field:         |
| <b>a</b>         | Specifies an <b>at</b> command event.                                                                                    |
| <b>b</b>         | Specifies a <b>batch</b> command event.                                                                                  |
| <b>c</b>         | Specifies a <b>crontab</b> command event.                                                                                |
| <b>d</b>         | Specifies a <b>sync</b> subroutine event.                                                                                |
| <b>e</b>         | Specifies a <b>ksh</b> command event.                                                                                    |
| <b>f</b>         | Specifies a <b>csh</b> command event.                                                                                    |
| <b>Jobsj</b>     | Specifies the maximum number of jobs the <b>cron</b> daemon can start at one time. The default value is 100.             |
| <b>Nicen</b>     | Specifies the nice value for job execution. The default value is 2.                                                      |
| <b>Waitw</b>     | Specifies the time, in seconds, to wait before attempting to execute the command again. The default value is 60 seconds. |

**Note:** You must have root user authority to modify this file.

The **at** command allows you to specify the time when a command should be run. Each command or program will be assigned a job number and will be queued in the **/var/spool/cron/atjobs** directory.

The queueing system may also be set up by defining a batch queue in the **/etc/qconfig** file and using the **enq** command to submit a job to this queue. This queue may be set up with a first-come, first-serve discipline. The following stanzas should be added to the **/etc/qconfig** file to enable this:

```
bsh
device = bshdev
discipline = fcfs
bshdev:
backend = usr/bin/sh
```

This configuration may already exist in the **/etc/qconfig** file. If you want your commands and programs to run under the Korn shell, you should change the last line in the above stanza to:

```
backend = usr/bin/ksh
```

After creating the above stanza in the **/etc/qconfig** file, enable the queue by issuing the following:  
**qchk -A**

Programs and commands may now be run on a first-come, first-serve basis using the **enq** command. For example, to run the program PROGRAM1 from the bsh queue, enter:

```
enq -P bsh PROGRAM1
```

The flags for the batch facility and queueing are:

| Item   | Description                      |
|--------|----------------------------------|
| at -qa | This is for queueing at jobs.    |
| at -qb | This is for queueing batch jobs. |
| at -qe | This is for queueing ksh jobs.   |
| at -qf | This is for queueing csh jobs.   |

## Examples

1. To set the **at** command job queue to handle 4 concurrent jobs with a nice value of 1 and no retries, enter:  
**a.4j1n**
2. To set the **crontab** command job queue to handle 2 concurrent jobs with a nice value of 2 and a retry in 90 seconds if the **fork** subroutine fails, enter:  
**c.2j2n90w**

## rc.net File Format for TCP/IP

### Purpose

Defines host configuration for network interfaces, host name, default gateway, and static routes.

### Description

The **/etc/rc.net** file is a shell script that contains configuration information. The stanzas allow you to enable the network interfaces and set the host name, the default gateway, and any static routes for the current host. This file can be used as a one-step configuration alternative to using individually the set of commands and files necessary to configure a host.

The **rc.net** shell script is run by the configuration manager program during the second phase of configuration. If TCP/IP is installed, a second script, **rc.tcpip**, is run from the **init** command after the second phase of configuration has completed and after the **init** command has started the SRC master.

Stanzas in the file should appear in the order in which they are presented here.

The **rc.net** shell script may also be run by the configuration manager program (**cfgmgr**) if **cfgmgr** is run after system configuration is completed. It is often run at other times to configure new devices that have been added to the system since boot time. If **cfgmgr** runs **rc.net**, both the configuration methods and **rc.net** itself check to see if networking devices are already in the Available state. If so, the values of device attributes are not changed to avoid overwriting any configuration changes that have been made since boot time.

If **/etc/rc.net** is run without **cfgmgr**, device attributes will be reset to the values in the ODM database regardless of the states of the devices. This allows a system's configuration to be restored to the values specified in the ODM database.

## Using the Configuration Methods

These stanzas use the configuration methods for TCP/IP to manipulate the ODM database.

### Configuring Network Interfaces

For each network adapter that has been previously configured, a set of stanzas is required. The following stanzas define, load, and configure the appropriate network interfaces for every configured network adapter. These configuration methods require that the interface and protocol information be entered in the ODM database, using either SMIT or high-level configuration commands such as the **mkdev** command. The network interface configuration information is held in the running system only and must be reset at each system restart.

```
/usr/lib/methods/defif >>
$LOGFILE 2>&1
/usr/lib/methods/cfgif $* >> $LOGFILE
2>&1
```

The **defif** method defines the network interfaces. The **cfgif** method configures the network interfaces in the configuration database.

The second part of the stanzas indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

Along with the network interface configuration, additional commands must be executed for X.25 and SLIP interfaces: the **x25ip** command for X.25 interfaces and the **slattach** command for SLIP connections. The **x25ip** command loads the X.25 translation table into the kernel and the **slattach** command is used to assign a TTY line to an interface for SLIP. For each SLIP interface, the **slattach** command must be executed for the appropriate TTY.

At times, when diskless clients reboot using these configuration methods they hang on LED 581. This happens because diskless clients use server disk space to store the logging information. To get the client to reboot when this happens, execute the **/usr/lib/methods/cfgif** configuration method in the client **rc.net** file that resides on the server without message logging as follows:

```
/usr/lib/methods/cfgif $*
```

### Setting the Host Name, Default Gateway, and Any Static Routes

The following stanzas set the host name, default gateway, and static routes, using the **definet** and **cfginet** subroutines to alter the ODM database for the **inet0** object.

```
/usr/lib/methods/definet >>
$LOGFILE 2>&1/usr/lib/methods/cfginet >> $LOGFILE
2>&1
```

The second part of the stanzas indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

## Using Traditional Configuration Commands

These stanzas use configuration commands for TCP/IP to set configuration values.

### Configuring Network Interfaces

The following stanza defines, loads, and configures the specified network interface:

```
/usr/sbin/ifconfig Interface inet
InternetAddress up>>$LOGFILE 2 &1
```

The *Interface* parameter should specify the type and number of the interface, for example, *tr0*. The *InternetAddress* parameter should specify the Internet address of the interface, for example, *192.1.8.0*.

The last part of the stanza indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

### Setting the Host Name, Default Gateway, and Any Static Routes

These stanzas should follow any stanzas for the network interfaces. These stanzas use the **hostname** command to set the host name and the **route** command to define the default gateway and any static routes. The static route information is held in the running system only and must be reset at each system restart.

```
/usr/bin/hostname Hostname >>
$LOGFILE 2>&1/usr/sbin/route add 0
Gateway >> $LOGFILE 2>&1
/usr/sbin/route add DestinationAddress
Gateway >>$LOGFILE 2>&1
```

The **add** variable for the **route** command adds a static route to the host. This route can be to the default gateway (by specifying a hop count, or metric, of 0), or to another host through a gateway.

The last part of the stanzas indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

### Miscellaneous Functions

Use these stanzas to set the host ID and user name. By default, the host ID and user name are set to the host name. However, these stanzas can be altered to customize the host ID and user name.

```
/usr/sbin/hostid `hostname'
/usr/bin/uname -s `hostname | sed -e 's/\..*$//'
>> $LOGFILE 2>&1
```

To customize these stanzas, replace the *hostname* entry in single quotation marks with the desired host ID or user name.

The second part of the user name stanza indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

## Load Network File System (NFS)

If you have the Network File System (NFS) installed on the current host, the following stanza loads and configures the NFS kernel extension:

```
if [-x /usr/sbin/gfsinstall -a
 -x /usr/lib/drivers/nfs.ext] ; then
 /usr/sbin/gfsinstall -a /usr/lib/drivers/
nfs.ext >>$LOGFILE 2>&1fi
```

The last part of the NFS stanza indicates that output should be sent to a log file. The log file must include the full path name. If no log file is specified, the default log file is **/dev/null**.

## Examples

1. To set up a Token-Ring interface, using the **ifconfig** command, include the following stanza:

```
/usr/sbin/ifconfig tr0 inet
 192.1.8.0 up >>$LOGFILE 2>&1
```

This stanza defines Token-Ring interface **tr0**, with the Internet address **192.1.8.0**.

2. To set the host name, using the **hostname** command, include the following stanza:

```
/usr/bin/hostname robo.austin.century.com
>>$LOGFILE 2>&1
```

This stanza sets host name **robo.austin.century.com**. The host name in this example includes domain and subdomain information, which is necessary if the host is using the domain naming system.

3. To set up a default gateway, using the **route** command, include the following stanza:

```
/usr/sbin/route add 0
192.100.13.7 >>$LOGFILE 2>&1
```

The value **0** for the *Metric* parameter means that any packets sent to destinations not previously defined and not on a directly connected network go through the default gateway. The **192.100.13.7** address is the default gateway.

4. To set up a static route, using the **route** command, include the following stanza:

```
/usr/sbin/route add net
192.100.201.7 192.100.13.7>>$LOGFILE 2>&1
```

The **192.100.201.7** address is the receiving computer (the *Destination* parameter). The **192.100.13.7** address is the routing computer (the *Gateway* parameter).

## Files

## rc.ntx File Format

### Purpose

Supplies configuration information for the Network Terminal Accelerator adapter card.

## Description

The `/etc/rc.ntx` file invokes the `hty_load` command to load the `/etc/hty_config` file. This file can also specify a route to a gateway, using the `ntx_route` command. Also, the `rc.ntx` file enables SNMP.

The `/etc/rc.ntx` file can be used to perform different configuration tasks. For example, to supply a route to an additional gateway, add the following line immediately after the comment about additional routes, and supply an IP address for the *Destination* and *Gateway* parameters:

```
/usr/bin/ntx_route -drhp$i net Destination
Gateway
```

Following is the file as it is shipped with the software package. You can add additional commands to the file, as indicated above.

```
echo "Executing hty_load"
/usr/bin/hty_load -f /etc/hty_config
echo "Finished executing hty_load"

#
Maximum number of Network Terminal Accelerator adapters
supported on each workstation.
#

MAX_RHP_DEVICES=7

i=0
while [$i -le $MAX_RHP_DEVICES]
do
 if [-f /etc/rhp$i.ntx_comun.conf]; then
 echo "Configuring SNMP communities on NTX
 Adapter rhp$i"
 /usr/bin/ntx_comun -d /dev/rhp$i -f
 /etc/rhp$i.ntx_comun.conf
 fi
 if [-f /etc/rhp$i.ntx_traps.conf]; then
 echo "Configuring SNMP traps on NTX Adapter rhp$i"
 /usr/bin/ntx_traps -d /dev/rhp$i -f
 /etc/rhp$i.ntx_traps.conf
 fi
 if [-f /etc/rhp$i.ntx_nms.conf]; then
 echo "Configuring SNMP nms on NTX Adapter rhp$i"
 /usr/bin/ntx_nms -d /dev/rhp$i -f
 /etc/rhp$i.ntx_nms.conf
 fi
 if [-f /etc/rhp$i.ntx_descr.conf]; then
 echo "Configuring SNMP site-specific variables on
 NTX Adapter rhp$i"
 /usr/bin/ntx_descr -d /dev/rhp$i -f
 /etc/rhp$i.ntx_descr.conf
 fi
 if [-c /dev/rhp$i]; then
 STATE=`lsattr -E -l rhp$i -a snmp -F value`
 echo "Turning $STATE SNMP on NTX Adapter rhp$i"
 /usr/bin/ntx_snmp -d /dev/rhp$i $STATE
 fi
 # Additional routes for each NTX Adapter can be added here
 # example: /usr/bin/ntx_route -d /dev/rhp$i X.X.X X.X.X.X

 i=`expr $i + 1` # increment count
done
```

## remote File Format for tip

### Purpose

Describes remote systems contacted by the **tip** command.

### Description

The **/etc/remote-file** file describes the remote systems that can be contacted using the **tip** command. When a user invokes the **tip** command, the command reads the **remote** file to find out how to contact the specified remote system. If invoked with the *SystemName* parameter, the **tip** command searches the **remote** file for an entry beginning with that system name. If invoked with the *PhoneNumber* parameter, the command searches the **remote** file for an entry beginning with **tipBaudRate**, where *BaudRate* designates the baud rate to be used for the connection.

Any **tip** user can create an individual remote file in the format of the **remote** file. The individual remote file can be named with any operating system file name and placed in any directory to which the user has access. To instruct the **tip** command to use the new file, set the **REMOTE** environment variable before issuing the **tip** command, or use the **tip** command **remote** variable.

A sample **remote** file for **tip** is included with the operating system. The sample file is named **/usr/lib/remote-file**. This sample file contains two examples, either of which is a complete **remote** file. One of the examples uses a set of general dialer definitions, followed by general system definitions, and specific systems. The second example defines each system individually.

Any user can copy the sample file to some other directory and modify it for individual use. A user with root user authority can copy the sample file to the **/etc/remote** file and modify it to suit the needs of a particular site.

### Format of Entries

The general format of an entry in the **/etc/remote-file** file is a system name, baud rate, or dialer name followed by a description and one or more attributes, as follows:

*SystemName[ | SystemName ...] | Description:Attribute[:Attribute ...]:*

OR

*tipBaudRate | Description: Attribute[:Attribute ...]:*

OR

*DialerName[ | DialerName ...] | Description:Attribute[:Attribute ...]:*

The name of the system or dialer is followed by a | (pipe symbol) and a description of the system or dialer. More than one system or dialer name can be given; in this case, they must be separated by pipe symbols and precede the *Description* parameter. The last section in this list is always treated by the **tip** command as a description, not a system name.

The *Description* field is followed by a : (colon) and a list of attributes separated by colons. Each entry must also end with a colon.

An entry can be continued on the next line by typing a \ (backslash). The continuation line must begin with a : (colon) and can be indented for readability.

Any line beginning with a # (pound sign) is read as a comment line.

**Note:** Spaces can be used only within the *Description* parameter or in comment lines.

## Attributes Used to Define Systems and Dialers

Use the following attributes to describe systems in the **remote** file:

| Item                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>at=ACUType</b>            | Defines the type of automatic calling unit (also known as the ACU or modem). This attribute should be specified in each entry (or in another entry included with the <b>tc</b> attribute) unless the system is linked to a modem. The <i>ACUType</i> must be one of the following: <ul style="list-style-type: none"><li>• <b>biz31f</b></li><li>• <b>biz31w</b></li><li>• <b>bix22f</b></li><li>• <b>biz22w</b></li><li>• <b>df02</b></li><li>• <b>df03</b></li><li>• <b>dn11</b></li><li>• <b>ventel</b></li><li>• <b>hayes</b></li><li>• <b>courier</b></li><li>• <b>vadic</b></li><li>• <b>v3451</b></li><li>• <b>v831</b></li></ul> |
| <b>br#BaudRate</b>           | Specifies the baud rate to be used on the connection. The default rate is 1200 baud. This attribute should be specified in each entry or in another entry included with the <b>tc</b> attribute. The baud rate specified can be overridden using the <b>tip</b> command <i>-BaudRate</i> parameter.                                                                                                                                                                                                                                                                                                                                      |
| <b>cu=Device</b>             | Specifies the device for the call unit if it is different from the device defined in the <b>dv</b> statement. The default is the device defined in the <b>dv</b> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>du</b>                    | Makes a call. This attribute must be specified in each entry or in another entry included with the <b>tc</b> attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>dv=Device[Device ...]</b> | Lists one or more devices to be used to link to the remote system. If the first device listed is not available, the <b>tip</b> command attempts to use the next device in the list, continuing until it finds one available or until it has tried all listed devices.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>e1=Mark</b>               | This attribute must be specified in each entry or in another entry included with the <b>tc</b> attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>fs=Size</b>               | Defines the mark used to designate an end-of-line in a file transfer. This setting is the same as that defined by the <b>tip</b> command <b>eol</b> variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ie=InputString</b>        | Specifies the frame size. The default is the value of the <b>BUFSIZ</b> environment variable. This value can also be changed using the <b>tip</b> command <b>framesize</b> variable.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>oe=OutputString</b>       | Specifies the input end-of-file mark. The default setting is null value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>pa=Parity</b>             | Specifies the output end-of-file mark. The default setting is a null value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|                              | Specifies the required parity setting for connecting to the remote system. The default setting is Even. Valid choices are: Even (7 bits, even parity), Odd (7 bits, odd parity), None (7 bits, no parity), and Graphic (8 bits, no parity).                                                                                                                                                                                                                                                                                                                                                                                              |

| Item                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pn=</b>           | <p>Lists telephone numbers to be used to call the remote system. This entry is required if a modem is used to call a remote system, except in a <b>tipBaudRate</b> entry when a telephone number is entered with the <b>tip</b> command.</p> <p>If the <b>tip</b> command is invoked with the <i>PhoneNumber</i> parameter, the <b>pn</b> attribute in the appropriate <b>tipBaudRate</b> entry is ignored and the number given when the command is invoked is used instead.</p> |
|                      | The <b>pn</b> attribute can be in either of the following forms:                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                      | <b>pn=@</b> Instructs <b>tip</b> to search the <b>/etc/phones-file</b> file, or the file specified with the <b>phones</b> variable, for the telephone number.                                                                                                                                                                                                                                                                                                                    |
|                      | <b>pn=Number[Number ...]</b><br>Lists one or more phone numbers to be used to call the remote system.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>tc=Entry</b>      | Refers to another entry in the file. This allows you to avoid defining the same attributes in more than one entry. If used, this attribute should be at the end of the entry.                                                                                                                                                                                                                                                                                                    |
| <b>tc=DialerName</b> | Includes the specified <i>DialerName</i> entry. The <i>DialerName</i> entry must be defined elsewhere in the <b>remote</b> file.                                                                                                                                                                                                                                                                                                                                                 |
| <b>tc=SystemName</b> | Includes the specified <i>SystemName</i> entry. The <i>SystemName</i> entry must be defined elsewhere in the <b>remote</b> file.                                                                                                                                                                                                                                                                                                                                                 |

## Setting Up Group Entries

Set up entries in the **remote** file in two ways. Define each system individually, giving all of its attributes in that entry. This works well if you are contacting several dissimilar systems.

Or group the systems by similarity. To do this, use two or three groups, depending on how the systems are similar. The groups can be arranged by:

- Dialer definitions, including the device, baud rate, call unit, ACU type, and dial-up connection flag.
- General system definitions, including any information that several systems have in common. Use the **tc** attribute to refer to a dialer entry.
- Specific system descriptions, which use the **tc** attribute to refer to one of the general system types or a dialer entry.

You can omit either the dialer definitions or the general system definitions, depending on the way the remote systems are grouped.

## Examples

### Defining a System Individually

To define a system without using the **tc=** attribute, enter:

```
vms750|ghost|NPG 750:\n :dv=/dev/tty36,/dev/tty37:br#9600:e]=^Z^U^C^S^Q^0:\n :ie=$@:oe=^Z:
```

This entry defines system *vms750*, which can also be referred to as *ghost*. The system can be accessed using either */dev/tty36* or */dev/tty37*, at a baud rate of 9600. The end-of-line mark is *^Z^U^C^S^Q^0*. The input end-of-file mark is *\$@* and the output end-of-file mark is *^Z*. Since no phone number is defined, the system is accessed over a direct connection.

### Grouping Systems by Similarity

The following examples use a dialer entry and a general system entry, followed by specific system entries that refer to the general entries.

1. To define a dialer, enter:

```
dial1200|1200 Baud Able Quadracall attributes:
\ :dv=/dev/cull:br#1200:at=dn11:du:
```

This entry defines a dialer called `dial1200`. The dialer is connected to device `/dev/cull` and is an ACU type of `dn11`. The dial-up connection (`du`) flag is set.

2. To define a general system type and refer to a dialer entry, enter:

```
unix1200|1200 Baud dial-out to another UNIX system:\ :el=^U^C^R^O^D^S^Q:ie=%$:oe=^D:tc=dial1200:
```

This entry defines a system type called `unix1200`. The end-of-line mark for communication with this type of remote system is `^U^C^R^O^D^S^Q`. The input end-of-file mark is `%$` and the output end-of-file mark is `^D`. The dialer defined by the `dial1200` entry is used.

3. To describe a specific system, enter:

```
zeus|CSRG ARPA VAX-11/780:pn=@:tc=unix1200:
```

This entry describes system `zeus`, which is described as a CSRG ARPA VAX-11. The `tip` command then searches the `/etc/phones` file for the telephone number (`pn=@`) and uses the attributes of a `unix1200` system type (`tc=unix1200`).

## Files

| Item                              | Description                                                     |
|-----------------------------------|-----------------------------------------------------------------|
| <code>/etc/remote</code>          | Denotes the complete path name of the <code>remote</code> file. |
| <code>/etc/phones</code>          | Lists the phone numbers used to contact remote systems.         |
| <code>/usr/lib/remote-file</code> | Contains an example <code>remote</code> file.                   |

## resolv.conf File Format for TCP/IP

### Purpose

Defines Domain Name Protocol (DOMAIN) name-server information for local resolver routines.

### Description

If the `/etc/resolv.conf` file exists, the local resolver routines either use a local name resolution database maintained by a local `named` daemon (a process) to resolve Internet names and addresses, or they use the Domain Name Protocol to request name resolution services from a remote DOMAIN name server host. If no `resolv.conf` file exist than the resolver routines continue searching their direct path, which may include searching through `/etc/hosts` file or the NIS hosts map.

**Note:** If the `resolv.conf` file does not exist, the resolver routines attempt name resolution using the default paths, the `/etc/netsvc.conf` file, or the NSORDER environment variable.

If the host is a name server, the `resolv.conf` file must exist and contain a nameserver reference to itself as well as a default domain.

The `resolv.conf` file can contain one domain entry or one search entry, a maximum of three nameserver entries, and any number of options entries.

A domain entry tells the resolver routines which default domain name to append to names that do not end with a . (period). There can be only one domain entry. This entry is of the form:

`domain DomainName`

The *DomainName* variable is the name of the local Internet domain. If there is no domain or search entry in the file, the **gethostbyname** subroutine returns the default domain (that is, everything following the first period). If the host name does not have a domain name included, the root domain is assumed.

A search entry defines the list of domains to search when resolving a name. Only one domain entry or search entry can be used. If the domain entry is used, the default search list is the default domain. A search entry should be used when a search list other than the default is required. The entry is of the form:

`search DomainName ...`

The search entry can have up to a maximum of 1024 character strings for the *DomainName* variable. The first *DomainName* variable is interpreted as the default domain name. The *DomainName* variable is the name of a domain that should be included in the search list.

**Note:**

1. The domain entry and search entry are mutually exclusive. If both entries are used, the one that appears last will override the other.
2. The resolver routines require you to set the default domain. If the default domain is not set in the `/etc/resolv.conf` file, then you must set it in the `HostName` on the machine.

A nameserver entry defines the Internet email address of a remote DOMAIN name server to the resolver routines on the local domain. This entry is of the form:

`nameserver Address`

The *Address* variable is the dotted decimal address of the remote name server. If more than one name server is listed, the resolver routines query each name server (in the order listed) until either the query succeeds or the maximum number of attempts have been made.

The *Address* variable is the address of the preferred network on which you want the address returned. The *Netmask* variable is the netmask of the corresponding network address.

The options entry specifies miscellaneous behaviors of the resolver. The entry is of the form:

`options OptionName`

The *OptionName* variable can have one of the following values:

| Item                    | Description                                                                                                                                                                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>debug</code>      | Turns on the RES_DEBUG resolver option, which enables resolver debugging.                                                                                                                                                                                                                                               |
| <code>ndots:n</code>    | Specifies that for a domain name with <i>n</i> or more periods (.) in it, the resolver should try to look up the domain name "as is" before applying the search list.                                                                                                                                                   |
| <code>timeout:n</code>  | Enables you to specify the initial timeout for a query to a nameserver. The default value is five seconds. The maximum value is 30 seconds. For the second and successive rounds of queries, the resolver doubles the initial timeout and is divided by the number of nameservers in the <code>resolv.conf</code> file. |
| <code>attempts:n</code> | Enables you to specify how many queries the resolver should send to each nameserver in the <code>resolv.conf</code> file before it stops execution. The default value is 4. The maximum value is 5.                                                                                                                     |
| <code>rotate</code>     | Enables the resolver to use all the nameservers in the <code>resolv.conf</code> file, not just the first one.                                                                                                                                                                                                           |
| <code>inet6</code>      | Uses or maps IPv6 in the <b>gethostbyname</b> subroutine.                                                                                                                                                                                                                                                               |

Entries in this file can be made using the System Management Interface Tool (SMIT), by using the `namerslv` command, or by creating and editing the file with an editor.

## Examples

To define a domain host that is not a name server, enter:

```
domain abc.aus.century.com
nameserver 192.9.201.1
nameserver 192.9.201.2
```

The example contains entries in the **resolv.conf** file for a host that is not a name server.

## resolv.ldap File Format for TCP/IP

### Purpose

Defines Lightweight Directory Access Protocol (LDAP) server information for **ldap** mechanism used by local resolver subroutines.

### Description

The **/etc/resolv.ldap** file specifies the IP address of the LDAP server, which contains the name resolution database. This database is used by the local resolver subroutines to resolve symbolic host names into Internet email addresses. LDAP server specifications are obtained from **resolv.ldap** file only for the **ldap** mechanism.

**Note:** Although still supported, the use of the **ldap** mechanism is not recommended. Instead, the use of the **nis\_ldap** mechanism is advised. For the **nis\_ldap** mechanism, use the **ldap.cfg** file for configuring the LDAP server and other details.

However, if the **resolv.ldap** file does not exist, then the resolver subroutines continue searching their direct paths, which may include searching through a DNS server, the **/etc/hosts** file, or the NIS hosts map. In addition to the default paths, the resolver subroutines may also use the **/etc/irs.conf** file, the **/etc/netsvc.conf** file, or the **NSORDER** environment variable.

The **resolv.ldap** file contains one **ldapserver** entry, which is required, and one **searchbase** entry, which is optional. The **ldapserver** entry specifies the Internet email address of the LDAP server to the resolver subroutines. The entry must take the following format:

```
ldapserver Address [Port]
```

The *Address* parameter specifies the dotted decimal address of the LDAP server. The *Port* parameter is optional; it specifies the port number that the LDAP server is listening on. If you do not specify the *Port* parameter, then it defaults to 389.

The **searchbase** optional entry specifies the base DN (distinguished name) of the name resolution database on the LDAP server. This entry must take the following format:

```
searchbase baseDN
```

The *baseDN* parameter specifies the starting point for the name resolution database on the LDAP server. If you do not define this entry, then the *searchbase* entry defaults to *cn=hosts*.

## Example

To define an LDAP server with an IP address 192.9.201.1, that listens on the port 636, and with a *searchbase* *cn=hosttab*, enter the following:

```
ldapserver 192.9.201.1 636
searchbase cn=hosttab
```

## Files

| Item             | Description                                 |
|------------------|---------------------------------------------|
| /etc/resolv.ldap | Contains the IP address of the LDAP server. |

## rfc1108 table

### Description

An rfc1108 table contains the mapping between AIX Trusted Network labels and rfc1108 labels. This mapping is used by the AIX Trusted Network implementation of RIPS0. A sample file containing this table is stored in the **/usr/samples/tcpip/rfc1108.example** directory.

Each entry in the file must have the following fields. Each field is separated by a “|” from the one preceding it. The entry is ended by the newline character.

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>index</b>    | Tracks the maximum number of the entries and designates an entry number for each entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>rfclable</b> | Specifies the rfc name for the label. These names are specified in RFC1108 that the U.S. Department of Defense published.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>rfcvalue</b> | Specifies the rfc value corresponding to <b>rfclabel</b> . These values are specified in RFC1108 that the U.S. Department of Defense published.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ourlabel</b> | Specifies the classification level that the AIX Trusted Network system uses. The system corresponds to the value of the <b>rfclabel</b> field for the purpose of translation between the RFC1108 labeling system and the local labeling system. Thus, the processing of a packet with the <b>rfclabel</b> field takes place at the corresponding <b>ourlabel</b> field. The specified classification level must be one of the classifications that are specified in the Label Encodings file that the local system uses.                                                                                                                    |
| <b>valid</b>    | Indicates whether datagrams, which is the information transmitted over the TCP/IP network, with labeling as specified previously are accepted or transmitted. This flag is not enforced.<br><br>A <b>1</b> in this field indicates that datagrams labeled as specified in this entry are processed unless other conditions preclude it. This is the default value.<br><br>A <b>0</b> in this field indicates that datagrams labeled as specified in this entry are neither accepted nor transmitted.<br><br>All other values for this field are not valid. If more than one character is supplied, only the first character is significant. |

## Examples

The following is an example of an rfc1108 file:

```
1|top secret|61|TOP SECRET|1
```

tninit command

## .rhosts File Format for TCP/IP

### Purpose

Specifies remote users that can use a local user account on a network.

### Description

The **\$HOME/.rhosts** file defines which remote hosts (computers on a network) can invoke certain commands on the local host without supplying a password. This file is a hidden file in the local user's home directory and must be owned by the local user. It is recommended that the permissions of the **.rhosts** file be set to 600 (read and write by the owner only). The group user and others should not have write permission for the **.rhosts** file. If write permission is granted to the group user (and others), then permission to invoke any command on the local host will not be given to the remote host . The format of the **\$HOME/.rhosts** file is:

*HostNameField* [*UserFieldName*]

When a remote command executes, the local host uses the local **/etc/hosts.equiv** file and the **\$HOME/.rhosts** file of the local user account to validate the remote host and remote user.

### Host-Name Field

The **.rhosts** file supports the following host-name entries:

```
+
HostName
-HostName
+@NetGroup
-@NetGroup
```

A + (plus sign) signifies that any host on the network is trusted. The HostName entry is the name of a remote host and signifies that any user logging in from HostName is trusted. A -HostName entry signifies that the host is not trusted. A +@NetGroup or -@NetGroup entry signifies that all hosts in the netgroup or no hosts in the netgroup, respectively, are trusted.

The @NetGroup parameter is used by Network Information Service (NIS) for grouping. Refer to the NIS **netgroup** file for more information.

### User-Name Field

The **.rhosts** file supports the following user-name entries:

```
+
UserName
-UserName
+@NetGroup
-@NetGroup
```

A + (plus sign) signifies that any user on the network is trusted. The UserName entry is the login name of the remote user and signifies that the user is trusted. If no user name is specified, the remote user name must match the local user name. A -UserName entry signifies that the user is not trusted. A +@NetGroup or -@NetGroup entry signifies that all users in the netgroup or no users in the netgroup, respectively, are trusted.

The @NetGroup parameter is used by NIS for grouping. Refer to the NIS **netgroup** file for more information.

## Examples

1. To allow remote users to log in to a local-user account, enter:

```
hamlet dewey
hamlet irving
```

These entries in the local user's **\$HOME/.rhosts** file allow users **dewey** and **irving** at remote host **hamlet** to log in as the local user on the local host.

2. To prevent any user on a given remote host from logging in to a local-user account, enter:

```
-hamlet
```

This entry in the local user's **\$HOME/.rhosts** file prevents any user on remote host **hamlet** from logging in as a local user on the local host.

3. To allow all hosts in a netgroup to log in to a local-user account, while restricting specified users, enter:

```
+@century -joe
+@century -mary
+@century
```

This entry in the local user's **\$HOME/.rhosts** file allows all hosts in the century netgroup to log in to the local host. However, users **joe** and **mary** are not trusted, and therefore are requested to supply a password. The deny, or - (minus sign), statements must precede the accept, or + (plus sign), statements in the list. The @ (at sign) signifies the network is using NIS grouping.

## Files

| Item            | Description                                                             |
|-----------------|-------------------------------------------------------------------------|
| /etc/host.equiv | Specifies remote systems that can execute commands on the local system. |
| netgroup        | Lists the groups of users on the network.                               |

# sccsfile File Format

## Purpose

Describes the format of a Source Code Control System (SCCS) file.

## Description

The SCCS file is an ASCII file consisting of the following logical parts:

| Item                | Description                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Checksum</b>     | The logical sum of all characters except the characters in the first line                                                              |
| <b>Delta table</b>  | Information about each delta including type, SCCS identification (SID) number, date and time of creation, and comments about the delta |
| <b>User Names</b>   | Login names, group names, or numerical group IDs of users who are allowed to add or remove deltas from the SCCS file                   |
| <b>Header flags</b> | Flags defining how some SCCS commands work with the SCCS file, or defining values for identification keywords in the file              |
| <b>Comments</b>     | Descriptive information about the file                                                                                                 |
| <b>Body</b>         | The actual text lines intermixed with control lines                                                                                    |

**Note:** Several lines in an SCCS file begin with the ASCII SOH (start-of-heading) character (octal 001). This character is called the *control character* and is represented graphically as the @ (at sign) in the following text. Any line described in the following text that does not begin with the control character contains text from the source file. Text lines cannot begin with the control character.

## Checksum

The checksum is the first line of an SCCS file. This line has the following format:

**@hNumber**

The control character and variables in the checksum line have the following meanings:

| Item          | Description                                                                                                                                                                                                                                                                     |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>@h</b>     | Designates a magic number of 064001 octal (or 0x6801).                                                                                                                                                                                                                          |
| <b>Number</b> | Represents the logical sum of all characters in the SCCS file (not including the characters in this line). It is recalculated each time the SCCS file is updated with SCCS commands, and is used to detect possibly damaging changes made to an SCCS file by non-SCCS commands. |

## Delta Table

Each time a group of changes, known as a delta, is made to an SCCS file, the delta table creates a new entry. Each entry contains descriptive information about the delta. The @s (at sign, letter s) character defines the beginning of a delta table entry, and the @e (at sign, letter e) character defines the end of the entry. For each delta created, there is a delta table entry in the following format:

```
@s NumberLinesInserted/NumberLinesDeleted/NumberLinesUnchanged
@d DeltaType SID Date Time UserID Number PreNumber
@i NumbersIncluded . . .
@x NumbersExcluded . . .
@g NumbersIgnored . . .
@m ModificationRequestNumber
@c Comments . . .
```

The control characters and variables in the delta table entries have the following meanings:

| <b>Item</b> | <b>Description</b>                                                                                                                                                                                                  |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>@s</b>   | Designates the first line of each entry, which contains the number of lines inserted, deleted, and unchanged from the previous delta.                                                                               |
| <b>@d</b>   | Designates the second line of each entry, which contains the following variables:                                                                                                                                   |
|             | <i>DeltaType</i>                                                                                                                                                                                                    |
|             | Type of delta. The letter d designates a normal delta; the letter r designates a delta that has been removed with the <b>rmDEL</b> command.                                                                         |
|             | <i>SID</i>                                                                                                                                                                                                          |
|             | SCCS ID (SID) of the delta.                                                                                                                                                                                         |
|             | <i>Date</i>                                                                                                                                                                                                         |
|             | Date, in the YY/MM/DD format, that the delta was created.                                                                                                                                                           |
|             | <i>Time</i>                                                                                                                                                                                                         |
|             | Time, in the HH:MM:SS format, that the delta was created.                                                                                                                                                           |
|             | <i>UserID</i>                                                                                                                                                                                                       |
|             | Login name that corresponds to the real user ID at the time the delta was created.                                                                                                                                  |
|             | <i>Number</i>                                                                                                                                                                                                       |
|             | Serial numbers of the delta.                                                                                                                                                                                        |
|             | <i>PreNumber</i>                                                                                                                                                                                                    |
|             | Serial numbers of the delta's predecessor.                                                                                                                                                                          |
| <b>@i</b>   | Indicates the serial numbers of the deltas that are included in the creation of this delta by using the <b>get</b> command with the <b>-i</b> flag. This line can contain several delta numbers and is optional.    |
| <b>@x</b>   | Indicates the serial numbers of the deltas that were excluded from the creation of this delta by using the <b>get</b> command with the <b>-x</b> flag. This line can contain several delta numbers and is optional. |
| <b>@g</b>   | Indicates the serial numbers of the deltas that were ignored in the creation of this delta by using the <b>delta</b> command with the <b>-g</b> flag. This line can contain several delta numbers and is optional.  |
| <b>@m</b>   | Indicates a modification request (MR) number associated with the delta. There can be several MR lines in an SCCS file, each one containing a different MR number. These lines are optional.                         |
| <b>@c</b>   | Comment lines associated with the delta. There can be several comment lines in an SCCS file. These lines are optional.                                                                                              |
| <b>@e</b>   | Ends the delta table entry.                                                                                                                                                                                         |

## User Names

This section of the file contains the list of login names, group names, or numerical group IDs of users who can add deltas to the file. The names and IDs are separated by new-line characters. This section uses the following control characters:

| <b>Item</b> | <b>Description</b>                                                                                                       |
|-------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>@u</b>   | A bracketing line that indicates the beginning of a user-name list. This line appears before the first line in the list. |
| <b>@U</b>   | A bracketing line that indicates the end of a user name list. This line appears after the last line in the list.         |

An empty list allows any user to make a delta. The list is changed using the **admin** command with the **-a** or **-e** flag.

## Header Flags

Flags control commands and define keywords used internally in the SCCS. Header flags are set using the **admin** command with various flags. The format of each line is:

**@f** *Flag Text*

The control character and variables in the header flags section have the following meanings:

| Item | Description                                                                                                                                                                                                                                                                                                                       |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| @fb  | Branch. Allows the use of the <b>-b</b> flag of the <b>get</b> command to cause a branch in the delta tree.                                                                                                                                                                                                                       |
| @fc  | Ceiling. Defines the highest release number from 0 through 9999 that can be retrieved by a <b>get</b> command for editing. This release number is called the <i>ceiling release number</i> .                                                                                                                                      |
| @fd  | Default SCCS ID. Defines the default SID to be used when one is not specified with a <b>get</b> command. When this flag is not set, the <b>get</b> command uses the most recently created delta.                                                                                                                                  |
| @ff  | Floor. Defines the lowest release number from 0 through 9999 that can be retrieved by a <b>get</b> command for editing. This release number is called the <i>floor release number</i> .                                                                                                                                           |
| @fi  | ID keywords. Controls the No ID keywords error warning message. When this flag is not set, the message is only a warning. When this flag is set, the absence of ID keywords causes an error and the delta fails.                                                                                                                  |
| @fj  | Joint edit. Causes the <b>get</b> command to allow concurrent edits of the same base SID.                                                                                                                                                                                                                                         |
| @fl  | Lock releases. Defines a list of releases that cannot be edited with the <b>get</b> command using the <b>-e</b> flag.                                                                                                                                                                                                             |
| @fm  | Module name. Defines the replacement of a module name for the <b>11</b> identification keyword. This value is used to override the default.                                                                                                                                                                                       |
| @fn  | No changes. Causes the <b>delta</b> command to insert null deltas (delta entries with no changes) for any skipped releases when a delta for a new release is created. For example, delta 5.1 is created after delta 2.1, skipping releases 3 and 4. When this flag is omitted, skipped releases are omitted from the delta table. |
| @fq  | User-defined flag. Defines the replacement of the identification keyword.                                                                                                                                                                                                                                                         |
| @ft  | Type of program. Defines the replacement of the identification keyword.                                                                                                                                                                                                                                                           |
| @fv  | Program name. Controls prompting for MR numbers in addition to comments on delta creation. If a value is assigned, it defines an MR number validity-checking program.                                                                                                                                                             |

## Comments

When comments are taken from a file containing descriptive text by using the **admin** command with the **-t** flag option, the contents of that file are displayed in the comments section. Typically, the comments section contains a description of the purpose of the entire file and uses the following control characters:

| Item | Description                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------|
| @t   | A bracketing line that indicates the beginning of the comments section. This line appears before the first comment line. |
| @T   | A bracketing line that indicates the end of the comments section. This line appears after the last comment line.         |

## Body

The body consists of two types of lines: control lines and text lines. Control lines bracket text lines. The text lines contain pieces of text that were inserted or deleted for a particular version of the file. The control lines that bracket a piece of text indicate whether a piece of text was inserted or deleted, and in what version. When a particular version of a file is created from the SCCS file, the control lines identify the pieces of text that should be added or deleted for that version of the file.

Control lines can be nested within one another, so the same portion of text can be bracketed by several sets of control lines. The body of a long SCCS file can be very complicated. The SCCS commands, however, provide a better way to understand the different versions of an SCCS file.

| Item     | Description                                                                                                                                                                                                                                                                                                                                                     |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| @INumber | Indicates an insert control line. The <i>Number</i> variable indicates the serial number that corresponds to the delta for the control line. Text inserted between this control line and an end control line with the same serial number was inserted as part of the delta that corresponded to the same serial number.                                         |
| @DNumber | Indicates a delete control line. The <i>Number</i> variable indicates the serial number that corresponds to the delta for the control line is indicated by the <i>Number</i> variable. Text deleted between this control line and an end control line with the same serial number was deleted as part of the delta that corresponded to the same serial number. |
| @ENumber | Indicates an end control line. The serial number that corresponds to the delta for the control line is indicated by the <i>Number</i> variable. This indicates the end of a section of text to be inserted or deleted.                                                                                                                                          |

Within the text are also identification keywords that are specific to the SCCS file system. These keywords represent identifying information about the SCCS file. When using the **get** command without the **-e** or **-k**

flag, these keywords will be replaced by their values. Because different versions have different identifying information, the identification keywords provide an easy way for the SCCS file system to provide the correct identifying information for any version of the file requested by the **get** command. Keywords can be used to provide several kinds of information:

- Version identification information:

| Keyword | Value                                                               |
|---------|---------------------------------------------------------------------|
| %M%     | Module name; the value of the <b>m</b> header flag in the SCCS file |
| %I%     | SID (1, 1, 0, 0)                                                    |
| %R%     | Release                                                             |
| %L%     | Level                                                               |
| %B%     | Branch                                                              |
| %S%     | Sequence                                                            |

- Time and date information:

| Keyword  | Value                                                   |
|----------|---------------------------------------------------------|
| 11/10/24 | Date of the current <b>get</b> command (YY/MM/DD)       |
| 10/24/11 | Date of the current <b>get</b> command (MM/DD/YY)       |
| 01:02:56 | Time of the current <b>get</b> command (HH:MM:SS)       |
| 11/05/10 | Date newest applied delta was created (YY/MM/DD)        |
| 5/10/11  | Date newest applied delta was created (MM/DD/YY)        |
| 06:12:56 | Time <i>newest applied</i> delta was created (HH:MM:SS) |

- Name information:

| Keyword                     | Value                           |
|-----------------------------|---------------------------------|
| /family/aix/vc/8/9/7/3/s.11 | SCCS file name                  |
| /family/aix/vc/8/9/7/3/s.11 | Full path name of the SCCS file |

- Flag values:

| Keyword | Value                                                                 |
|---------|-----------------------------------------------------------------------|
| -q      | Value of the <b>-q</b> header flag in the SCCS file.                  |
| -t      | Module type; the value of the <b>-t</b> header flag in the SCCS file. |

- Line numbers:

| Keyword | Value                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| 562     | The current line number. This keyword identifies message output by the program. It should not be used on every line to provide sequence numbers. |

- Constructing **what** strings:

| Keyword                                                      | Value                                                                                                                                                                                                                                          |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| src/idd/en_US/files/aixfiles/scsfile.ide, idaixfiles, idd71D | A shorthand notation for constructing <b>what</b> strings for program files specific to other operating systems. Its value equals the following key letters:<br>src/idd/en_US/files/aixfiles/scsfile.ide, idaixfiles, idd71D = @(#)11<tab>1.14 |
| @(#) 11 1.14@(#)                                             | Another shorthand notation for constructing <b>what</b> strings for program files specific to this operating system. Its value is the characters and key letters:<br>@(#) 11 1.14@(#) = @(#) 11 1.14 @(#)                                      |
| @(#)                                                         | The 4-character string @(#) (at sign, left parenthesis, pound sign, right parenthesis) recognized by the <b>what</b> command.                                                                                                                  |

## **sendh\_anchor File Format for TCP/IP**

### **Purpose**

Defines the trusted anchor for the **ndpd-host** daemon.

### **Description**

The **/etc/ndpd/sendh\_anchor** file is the default trust anchor file for the **ndpd-host** daemon. If the **ndpd-host** daemon is started without specifying an alternate file through the **/etc/ndpd/ndpdh.cnf** file or a user-specified configuration file, the application will read the **/etc/ndpd/sendh\_anchor** file for information about the trust anchor.

The format of the **sendh\_anchor** file when configuring the **ndpd-host** daemon is shown as follows:

| Keyword                                                         | Value                           | Description                                               |
|-----------------------------------------------------------------|---------------------------------|-----------------------------------------------------------|
| -----BEGIN CERTIFICATE-----<br><value>-----END CERTIFICATE----- | Certificate of the trust anchor | Certificate to be used to validate Router Advertisements. |

### **Files**

| Item                                        | Description                                   |
|---------------------------------------------|-----------------------------------------------|
| <b>/usr/samples/tcpip/send/sendh_anchor</b> | Contains the sample <b>sendh_anchor</b> file. |

## **sendr\_anchor File Format for TCP/IP**

### **Purpose**

Defines the trusted anchors for the **ndpd-router** daemon.

### **Description**

The **/etc/ndpd/sendr\_anchor** file is the trust anchor file for the **ndpd-router** daemon.

The keywords, values and the corresponding meaning of each value of the **sendr\_anchor** file for configuring the **ndpd-hostis** are shown as follows:

| <b>Keyword</b>                                                  | <b>Value</b>                | <b>Description</b>                                                                                                                                                                        |
|-----------------------------------------------------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -----BEGIN CERTIFICATE-----<br><value>-----END CERTIFICATE----- | an X509v3 type certificate  | One or more certificates of a chain, starting from the certificate of the topmost router to the certificate of this router.                                                               |
| -----BEGIN RSA PRIVATE KEY----- <value>                         | private key for this router | Private key that corresponds to the public key embedded in the certificate of this router. This keyword must be the last entry in the file, which follows the certificate of this router. |
| -----END RSA PRIVATE KEY-----                                   |                             |                                                                                                                                                                                           |

## Files

| <b>Item</b>                          | <b>Description</b>                            |
|--------------------------------------|-----------------------------------------------|
| /usr/samples/tcpip/send/sendr_anchor | Contains the sample <b>sendr_anchor</b> file. |

## services File Format for TCP/IP

### Purpose

Defines the sockets and protocols used for Internet services.

### Description

The **/etc/services** file contains information about the known services used in the DARPA Internet network. Each service is listed on a single line corresponding to the form:

*ServiceName PortNumber/ProtocolName Aliases*

These fields contain the following information:

| <b>Item</b>         | <b>Description</b>                                     |
|---------------------|--------------------------------------------------------|
| <i>ServiceName</i>  | Specifies an official Internet service name.           |
| <i>PortNumber</i>   | Specifies the socket port number used for the service. |
| <i>ProtocolName</i> | Specifies the transport protocol used for the service. |
| <i>Aliases</i>      | Specifies a list of unofficial service names.          |

Items on a line are separated by spaces or tabs. Comments begin with a # (pound sign) and continue until the end of the line.

The service and alias names are case sensitive.

If you edit the **/etc/services** file, run the **refresh -s inetd** or **kill -1 InetdPID** command to inform the **inetd** daemon of the changes.

### Examples

Entries in the **services** file for the **inetd** internal services may look like this:

```
echo 7/tcp
echo 7/udp
discard 9/tcp sink null
discard 9/udp sink null
daytime 13/tcp
daytime 13/udp
chargen 19/tcp ttyst source
chargen 19/udp ttyst source
ftp 21/tcp
time 37/tcp timeserver
time 37/udp timeserver
```

## **setmaps File Format**

### **Purpose**

Defines the text of a code-set map file and a terminal map file.

### **Description**

The text of a code set map file consists of a description of the code set. The text of a terminal map file consists of a set of rules.

#### **Code-Set Map File**

The text of a code set map file is a description of the code set. It specifies the optional converter modules to push on the stream. The code set map file is located in the **/usr/lib/nls/csmmap** directory. Its name is the code set name.

The code set map file contains the following lines:

| Item                 | Description                    |
|----------------------|--------------------------------|
| Name :               | <i>name</i>                    |
| Type :               | M   S                          |
| Multibyte handling : | EUC                            |
| ioctl EUC_WSET :     | <i>w1:d1, w2:d2, w3:d3</i>     |
| lower converter :    | <i>/usr/lib/drivers/lwconv</i> |
| upper converter :    | <i>/usr/lib/drivers/upconv</i> |

The lines have the following meaning:

| Item               | Description                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name               | Specifies the code set name. It is also the code set map file name.                                                                                                                                                                                                                               |
| Type               | Specifies the code set type. It can be one of the following:<br><br>M      Denotes a multibyte code set.<br>S      Denotes a single byte code set.                                                                                                                                                |
| Multibyte handling | Specifies the type of multibyte handling of the code set. This line is required only if Type is M. It must be EUC, denoting an EUC multibyte code set.                                                                                                                                            |
| ioctl EUC_WSET     | Specifies the parameters for the EUC_WSET ioctl operation. This line is required only if Type is M. The <i>w1</i> , <i>w2</i> , and <i>w3</i> parameters specify the memory width of the code set; the <i>d1</i> , <i>d2</i> , and <i>d3</i> parameters specify the screen width of the code set. |
| lower converter    | Specifies the lower and upper converters to use on the stream. This line is required only if the code set is a non-EUC multibyte code set.                                                                                                                                                        |
| upper converter    | Specifies the lower and upper converters to use on the stream. This line is required only if the code set is a non-EUC multibyte code set.                                                                                                                                                        |

For example, the code set map file for the ISO 8859-1 code set would contain the following lines:

Name: ISO8859-1  
Type: S

Another example: the code set map file for the IBM-943 code set would contain the following lines:

```
Name : IBM-943
Type : M
Multibyte handling : EUC
ioctl_EUC_WSET : 2:2,1:1,2:2
lower converter : /usr/lib/drivers/lc_sjis
upper converter : /usr/lib/drivers/up_sjis
```

## Terminal Map File

The text of a terminal map file is a set of rules. Each rule has the following format:  
pattern:replacement

The size of the input pattern string is limited to 10 characters in length and the size of the replacement pattern string is limited to 16 characters in length.

The pattern string can include the following special characters:

| Item          | Description                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ?<br>@x       | Matches any single byte.<br>Matches this rule only if the pattern processor is in state <i>x</i> , where <i>x</i> is any single byte. (This sequence does not match a character in the input buffer.) |
| \?, \@, or \\ | Prevents the pattern processor from interpreting ? (question mark), @ (at sign), or \ (backslash) as special characters.                                                                              |
| \ddd<br>\xdd  | Represents any byte in octal notation.<br>Represents any byte in hexadecimal notation.                                                                                                                |

The replacement string can include the following special characters:

| Item           | Description                                                                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$n<br>@x      | Uses the <i>n</i> th character in the input string that matched this pattern, where <i>n</i> is a decimal digit.<br>Moves the pattern processor into state <i>x</i> . (This sequence does not become part of the replacement string.) |
| \\$, \@, or \\ | Prevents the pattern processor from interpreting \$, @, or \ as special characters.                                                                                                                                                   |
| \ddd<br>\xdd   | Represents any byte in octal notation.<br>Represents any byte in hexadecimal notation.                                                                                                                                                |

## Files

| Item                         | Description                              |
|------------------------------|------------------------------------------|
| /usr/lib/nls/csmap/sbcs      | Code set map for a single-byte code page |
| /usr/lib/nls/csmap/IBM-932   | Code set map for the IBM-932 code page   |
| /usr/lib/nls/csmap/IBM-943   | Code set map for the IBM-943 code page   |
| /usr/lib/nls/csmap/IBM-eucJP | Code set map for the IBM-eucJP code page |
| /usr/lib/nls/csmap/IBM-eucKR | Code set map for the IBM-eucKR code page |
| /usr/lib/nls/csmap/IBM-eucTW | Code set map for the IBM-eucTW code page |
| /usr/lib/nls/termmap/*.in    | Input map files                          |
| /usr/lib/nls/termmap/*.out   | Output map files                         |

tty Subsystem Overview

## **simprof File Format**

### **Purpose**

Specifies PC Simulator startup options.

### **Description**

When you start PC Simulator with the **pcsim** command, PC Simulator searches for a profile of startup options. The profile used by PC Simulator is the **simprof** file format. It is a pure ASCII text file that you can edit with any text editor.

You can specify the name of a profile with the **-profile** flag at the **pcsim** command. If you do not enter a **-profile** flag, PC Simulator searches for the **simprof** default profile. This sample profile, included with PC Simulator, is located in the **/usr/lpp/pcsim/samples** directory.

You can define more than one profile. These profiles can be for different users or for starting PC Simulator with different options. PC Simulator first searches for the specified profile in the current working directory, then in the **\$HOME** directory, and finally in the **/usr/lpp/pcsim** directory. To operate with only one profile, you can copy the **simprof** sample profile to one of these directories, and edit it to set the options you want.

Even if PC Simulator finds a profile, it searches all three directories. It can, therefore, find more than one profile with the same file name. If this happens, PC Simulator accumulates options from each profile. It overlays values for the same option in each profile and uses the last value it reads. You can set options with flags from the command line that override any options in a profile.

### **Examples**

A simulator profile resembles an AIXwindows default profile. Options are listed by flag name, followed by a : (colon), then a parameter value. The **simprof** sample profile included with PC Simulator is similar to this example, except that it includes no parameter values.

If an option is not listed or no value is specified, PC Simulator starts with the default value for this option. A blank space between the colon and parameter value is optional. Any text following a # (pound sign) is a comment. PC Simulator expands environment variables inside the **simprof** file.

**Note:** If there is no diskette drive present, the entries for Adiskette and Bdiskette should be removed from the profile. If there is only one diskette drive present, the entry for Bdiskette should be removed from the profile.

```
Cdrive : /home/dos1/txt.fil # select file /home/dos1/txt.fil
 # for fixed disk C:
Ddrive : /home/dos2 # select directory /home/dos2
 # for fixed disk D:

## Standard Resource Record Format for TCP/IP

### Purpose

Defines the format of lines in the **named** data files.

### Description

Records in the **named** files are called *resource records*. Files using the standard resource record format are:

- **DOMAIN** data file
- **DOMAIN reverse** data file
- **DOMAIN cache** file
- **DOMAIN local** file

Resource records in the **named** files have the following general format:

{Name} {TTL} AddressClass RecordType RecordSpecificData

#### Field Definitions

|              |                                                                                                                                                                                                                                                                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name         | Varies depending on the <i>RecordType</i> field. The <i>Name</i> field can specify the name of a domain, a zone of authority, the name of a host, the alias of a host or of a mailbox, or a user login ID. The <i>Name</i> field must begin in column one. If this field is left blank, the name defaults to the value of the previous resource record. |
| TTL          | Time to live. This specifies how long the record is stored in the database. If this field is left blank, the time to live defaults to the time to live specified in the start of authority record. This field is optional.                                                                                                                              |
| AddressClass | Address class of the record. There are three valid entries for this field: ANY for all address classes, IN for Internet, and CHAOS for Chaos net.                                                                                                                                                                                                       |
| RecordType   | The type of resource record. Valid record types are:                                                                                                                                                                                                                                                                                                    |
| SOA          | Start of authority record                                                                                                                                                                                                                                                                                                                               |
| NS           | Name server record                                                                                                                                                                                                                                                                                                                                      |

| MG           | Mail group member record                                                                                                                                                                                                                                                                                                                                |

## Field Definitions

**MX**

Mail exchanger record

*RecordSpecificData*

Details and examples of record types are given below.  
These fields are dependent on the *RecordType* field.

Although case distinctions are kept when loading databases, all queries to the name server database are case insensitive.

The following characters have special meanings:

### Special Characters

.

If used in the *Name* field, a . (period) indicates the current domain.

**Note:** Use the . (period) at the end of resource records to append the path of the current domain.

..

If used in the *Name* field, two periods indicate the null domain name of the root domain.

@

If used in the *Name* field, an @ (at sign) indicates the current origin.

\X

Where X is any character except numbers 0 through 9 or the character . (period), a backslash preceding a character indicates that the character's special meaning should not be used. For example, \@ (backslash, at sign) can be used to put an @ character in the label of an entry in the *Name* field.

\DDD

Where each D is any number between 0 and 9. Each number is identified as the binary octet corresponding to the number. These octets are not checked for special meaning.

**Note:** The \DDD character is not used in the *Name* field of a resource record.

( )

Parentheses indicate that data broken into more than one line should be grouped together. The () (parentheses) are currently used in the **SOA** and **WKS** resource records.

;

Indicates a comment line. All characters after the ; (semicolon) are ignored.

\*

An \* (asterisk) indicates wildcards.

**Note:** The \* (asterisk) character is not used in the *Name* field of a resource record.

There are two special types of lines that are not data lines. Instead they specify special processing. These lines are the **\$INCLUDE** and **\$ORIGIN** lines.

### Special Types of Lines

**\$INCLUDE** *FileName*

This line begins in column one and is followed by a file name. It indicates that the specified file should be included in the name server database. This is useful in separating different types of data into multiple files. For example:

`$INCLUDE /usr/named/data/mailbox`

indicates that this file should be loaded into the name server's database. Data files specified by the **\$INCLUDE** line are not treated differently from any other **named** data file.

**\$ORIGIN** *OriginName*

This line begins in column one and is followed by the name of a domain. This line indicates that the origin from more than one domain in a data file should be changed.

## Resource Record Types

Following is a list of the resource record types used in the **named** data files:

- Start of authority record
- Name server record
- Address record
- Host information record
- Well-known services record
- Canonical name record

- IN-ADDR.ARPA record
- Domain-name pointer record
- Gateway PTR record
- Mailbox record
- Mail rename name record
- Mailbox information record
- Mail group member record
- Mail exchanger record

### Start of Authority Record

The start of authority (**SOA**) record indicates the start of a zone of authority. There should be only one start of authority record per zone, indicated by a value of **SOA** in the *RecordType* field. However, the **SOA** record for the zone should be in each **named.data** and **named.rev** file on each name server in the zone. Its structure corresponds to the following format:

```
{Name}{TTL} AddressClass RecordType Origin PersonInCharge @ IN SOA merl.century.com
jane.merl.century.com (1.1 ;Serial 3600 ;Refresh 600 ;Retry 3600000 ;Expire 86400) ;Minimum
```

### Fields

| Item                  | Description                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>           | Name of the zone.                                                                                                                                                                                            |
| <i>TTL</i>            | Time to live.                                                                                                                                                                                                |
| <i>AddressClass</i>   | Internet (IN).                                                                                                                                                                                               |
| <i>RecordType</i>     | Start of authority ( <b>SOA</b> ).                                                                                                                                                                           |
| <i>Origin</i>         | Name of the host on which this data file resides.                                                                                                                                                            |
| <i>PersonInCharge</i> | Person responsible for keeping the data file current. The format is similar to a mailing address, but the @ (at sign) that normally separates the user from the host name is replaced by a . (period).       |
| <i>Serial</i>         | Version number of this data file. This number should be incremented each time a change is made to the data. The upper limit for the number to the right of the decimal point is 9999.                        |
| <i>Refresh</i>        | The number of seconds after which a secondary name server checks with the primary name server to see if an update is needed. A suggested value for this field is 3600 (1 hour).                              |
| <i>Retry</i>          | The number of seconds after which a secondary name server is to retry after a refresh attempt fails. A suggested value for this field is 600 (10 minutes).                                                   |
| <i>Expire</i>         | The upper limit in seconds that a secondary name server can use the data before it expires because it has not been refreshed. This value should be fairly large, and a suggested value is 3600000 (42 days). |
| <i>Minimum</i>        | The minimum time, in seconds, to use as time-to-live values in resource records. A suggested value is 86400 (one day).                                                                                       |

### Name Server Record

The name server record specifies the name server responsible for a given domain. There should be one name server record for each primary server for the domain, indicated by a value of **NS** in the *RecordType* field. The name server record can be in the **named.data** file, the **named.rev** file, the **named.ca** file, and the **named.local** file. Its structure corresponds to the following format:

```
{Name} {TTL} AddressClass RecordType NameServerName
IN NS arthur.century.com
```

### Fields

| Item                  | Description                                                                                                                                 |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>           | Indicates the domain serviced by the specified name server. In this case, the domain defaults to the value in the previous resource record. |
| <i>TTL</i>            | Time to live.                                                                                                                               |
| <i>AddressClass</i>   | Internet (IN).                                                                                                                              |
| <i>RecordType</i>     | Name server (NS).                                                                                                                           |
| <i>NameServerName</i> | The name server responsible for the specified domain.                                                                                       |

## Address Record

The address record specifies the address for the host and is indicated by a value of **A** in the *RecordType* field. Address records can be entries in the **named.ca**, **named.data**, and **named.rev** files. Its structure corresponds to the following format:

```
{Name} {TTL} AddressClass RecordType Address
arthur IN A 132.10.8.1
 IN A 10.0.4.1
```

### Fields

| Item                | Description                                                                                                                    |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>         | Name of the host.                                                                                                              |
| <i>TTL</i>          | Time to live.                                                                                                                  |
| <i>AddressClass</i> | Internet (IN).                                                                                                                 |
| <i>RecordType</i>   | Address (A).                                                                                                                   |
| <i>Address</i>      | Internet address of the host in dotted decimal form. There should be one address record for each Internet address of the host. |

If the name server host for a particular domain resides inside the domain, then an **A** (address) resource record that specifies the address of the server is required. This address record is only needed in the server delegating the domain, not in the domain itself. If, for example, the server for domain `aus.century.com` was `fran.aus.century.com`, then the NS record and the required A record would look like:

```
aus.century.com. IN NS fran.aus.century.com.
fran.aus.century.com. IN A 192.9.201.14
```

## Host Information Record

The host information (**HINFO**) record lists host specific information, and is indicated by **HINFO** in the *RecordType* field. This lists the hardware and operating system that are running at the specified host. Note that the hardware and operating system information is separated by a single space. There must be one host information record for each host. The **HINFO** record is a valid entry in the **named.data** and the **named.rev** files. Its structure corresponds to the following format:

```
{Name} {TTL} AddressClass RecordType Hardware OS
```

### Fields

| Item                | Description                                                              |
|---------------------|--------------------------------------------------------------------------|
| <i>Name</i>         | Name of the host.                                                        |
| <i>TTL</i>          | Time to live.                                                            |
| <i>AddressClass</i> | Address class. Valid values are IN for Internet and CHAOS for Chaos net. |
| <i>RecordType</i>   | Host information ( <b>HINFO</b> ).                                       |
| <i>Hardware</i>     | Make and model of hardware.                                              |
| <i>OS</i>           | Name of the operating system running on the host.                        |

## Well-Known Services Record

The well-known services (**WKS**) record lists the well-known services supported by a particular protocol at a specified address. This record is indicated by **WKS** in the *RecordType* field. Although TCP/IP provides the record for backward compatibility, it is now obsolete.

The services and port numbers come from the list of services in the */etc/services* file. There should be only one **WKS** record per protocol per address. The **WKS** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

{*Name*} {*TTL*} *AddressClass* *RecordType* *Address* *Protocol* *ListOfServices*

|    |     |            |     |                                  |
|----|-----|------------|-----|----------------------------------|
| IN | WKS | 125.10.0.4 | UDP | (who route timed domain)         |
| IN | WKS | 125.10.0.4 | TCP | (echo telnet ftp netstat finger) |

## Fields

| Item                  | Description                                                                                                 |
|-----------------------|-------------------------------------------------------------------------------------------------------------|
| <i>Name</i>           | Name of the host. In this case, the name of the host defaults to the value in the previous resource record. |
| <i>TTL</i>            | Time to live                                                                                                |
| <i>AddressClass</i>   | Internet (IN)                                                                                               |
| <i>RecordType</i>     | Well-known services ( <b>WKS</b> )                                                                          |
| <i>Address</i>        | Internet address of the adapter in dotted decimal form                                                      |
| <i>Protocol</i>       | Protocol used by the list of services at the specified address                                              |
| <i>ListOfServices</i> | Services supported by a protocol at the specified address                                                   |

## Canonical Name Record

The canonical name record specifies an alias for a canonical name (**CNAME**), and is indicated by **CNAME** in the *RecordType* field. The **CNAME** record is the only Resource record that can use the alias of a canonical name. All other resource records must use the full canonical (or domain) name. The **CNAME** record is a valid entry in the **named.data** file. For each **CNAME** record, there must be a corresponding address (A) record. Its structure corresponds to the following format:

{*Aliases*} {*TTL*} *AddressClass* *RecordType* *CanonicalName*

|        |    |       |          |
|--------|----|-------|----------|
| knight | IN | CNAME | lancelot |
| john   | IN | CNAME | lancelot |

## Fields

| Item                 | Description                             |
|----------------------|-----------------------------------------|
| <i>Aliases</i>       | Alias by which the host is known        |
| <i>TTL</i>           | Time to live                            |
| <i>AddressClass</i>  | Internet (IN)                           |
| <i>RecordType</i>    | Canonical name (CNAME)                  |
| <i>CanonicalName</i> | Official name associated with the alias |

## IN-ADDR.ARPA Record

The structure of names in the domain system is set up in a hierarchical fashion. The address of a name can be found by tracing down the domain structure, contacting a server for each label in the name. Because the structure is based on names, there is no easy way to translate a host address back into its host name.

In order to allow simple reverse translation, the IN-ADDR.ARPA domain was created. This domain uses host addresses as part of a name that points to the data for that host. The IN-ADDR.ARPA domain provides an index to the resource records of each host based on its address. There are subdomains within the IN-ADDR.ARPA domain for each network, based on network number. Also, to maintain consistency and natural groupings, the 4 octets of a host number are reversed. The IN-ADDR.ARPA domain is defined by the IN-ADDR.ARPA record in the **named.boot** files and the DOMAIN hosts data file.

For example, the ARPANET is net 10, which means that there is a domain called 10.in-addr.arpa. Within this domain, there is a PTR resource record at 51.0.0.10.IN-ADDR, which points to the resource records for the host sri-nic.arpa (whose address is 10.0.0.51). Since the NIC is also on the MILNET (net 26, address 26.0.0.73), there is also a PTR resource record at 73.0.0.26.in-addr.arpa that points to the same resource records for SRI-NIC.ARPA. The format of these special pointers is defined in the following section on PTR resource records, along with the examples for the NIC.

## Domain-Name Pointer Record

The Domain-Name Pointer record allows special names to point to some other location in the domain. This record is indicated by **PTR** in the *RecordType* field. PTR resource records are mainly used in IN-ADDR.ARPA records to translate addresses to names.

**Note:** PTR records should use official host names, not aliases.

The PTR record is a valid entry in the **named.rev** file. Its structure corresponds to the following format:

```
{Aliases} {TTL} AddressClass RecordType RealName
 7.0 IN PTR arthur.century.com.
```

## Fields

| Item                | Description                                                                                                                                                                                                                                                               |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Aliases</i>      | Specifies where this record should point in the domain. Also specifies the Internet address of the host with the octets in reverse order. If you have not defined the IN-ADDR.ARPA domain in your <b>named.boot</b> file, this address must be followed by .in-addr.arpa. |
| <i>TTL</i>          | Time to live.                                                                                                                                                                                                                                                             |
| <i>AddressClass</i> | Internet (IN).                                                                                                                                                                                                                                                            |
| <i>RecordType</i>   | Pointer (PTR).                                                                                                                                                                                                                                                            |
| <i>RealName</i>     | The domain name of the host to which this record points.                                                                                                                                                                                                                  |

## Gateway PTR Record

The IN-ADDR domain is also used to locate gateways on a particular network. Gateways have the same kind of PTR resource records as hosts, but they also have other PTR records used to locate them by network number alone. These records have 1, 2, or 3 octets as part of the name, depending on whether they are class A, B, or C networks, respectively.

The gateway host named gw, for example, connects three different networks, one for each class, A, B, and C. The gw gateway has the standard resource records for a host in the cs1.sri.com zone:

```
gw.cs1.sri.com. IN A 10.2.0.2
 IN A 128.18.1.1
 IN A 192.12.33.2
```

In addition, this gateway has one of the following pairs of number-to-name translation pointers and gateway location pointers in each of the three different zones (one for each network). In each example, the number-to-name pointer is listed first, followed by the gateway location pointer.

### Class A

```
2.0.2.10.in-addr.arpa. IN PTR gw.cs1.sri.com.
10.in-addr.arpa. IN PTR gw.cs1.sri.com.
```

### Class B

```
1.1.18.128.in-addr.arpa. IN PTR gw.cs1.sri.com.
18.128.in-addr.arpa. IN PTR gw.cs1.sri.com.
```

### Class C

```
2.33.12.192.in-addr.arpa. IN PTR gw.cs1.sri.com.
33.12.192.in-addr.arpa. IN PTR gw.cs1.sri.com.
```

For example, a user named elizabeth used the following resource record to have her mail delivered to host venus.abc.aus.century.com:

```
elizabeth IN MB venus.abc.aus.century.com.
```

## Mailbox Record

The mailbox (MB) record defines the machine where a user wants to receive mail, and is indicated by **MB** in the *RecordType* field. The **MB** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

{Aliases} {TTL} AddressClass RecordType Machine  
jane IN MB merlin.century.com

## Fields

| Item         | Description                                                 |
|--------------|-------------------------------------------------------------|
| Aliases      | The user login ID                                           |
| TTL          | Time to live                                                |
| AddressClass | Internet (IN)                                               |
| RecordType   | Mailbox ( <b>MB</b> )                                       |
| Machine      | Name of the machine at which the user wants to receive mail |

## Mail Rename Name Record

The mail rename (MR) name record allows a user to receive mail addressed to a list of aliases. This record is indicated by **MR** in the *RecordType* field. The **MR** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

{Aliases} {TTL} AddressClass RecordType CorrespondingMB

merlin IN MR jane

## Fields

| Item                   | Description                                                                        |
|------------------------|------------------------------------------------------------------------------------|
| <i>Aliases</i>         | Alias for the mailbox name listed in the last field.                               |
| <i>TTL</i>             | Time to live.                                                                      |
| <i>AddressClass</i>    | Internet (IN).                                                                     |
| <i>RecordType</i>      | Mail rename ( <b>MR</b> ).                                                         |
| <i>CorrespondingMB</i> | The name of the mailbox. This record should have a corresponding <b>MB</b> record. |

## Mailbox Information Record

The mailbox information (**MINFO**) record creates a mail group for a mailing list, and is indicated by **MINFO** in the *RecordType* field. This record usually has a corresponding mail group record, but may also be used with a mailbox record. The **MINFO** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

{Name} {TTL} AddressClass RecordType Requests Maintainer  
postmaster IN MINFO post-request greg.century.com

## Fields

| Item                | Description                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>         | The name of the mailbox.                                                                                                                          |
| <i>TTL</i>          | Time to live.                                                                                                                                     |
| <i>AddressClass</i> | Internet (IN).                                                                                                                                    |
| <i>RecordType</i>   | Mail Information record ( <b>MINFO</b> ).                                                                                                         |
| <i>Requests</i>     | Where mail requests (such as a request to be added to the mailing list) should be sent.                                                           |
| <i>Maintainer</i>   | The mailbox that should receive error messages. This is particularly useful when mail errors should be reported to someone other than the sender. |

## Mail Group Member Record

The mail group member (**MG**) record lists the members of a mail group. This record is indicated by **MG** in the *RecordType* field. The **MG** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

{MailGroupName} {TTL} AddressClass RecordType MemberName  
dept IN MG Tom

## Fields

| Item                 | Description                             |
|----------------------|-----------------------------------------|
| <i>MailGroupName</i> | Name of the mail group.                 |
| <i>TTL</i>           | Time to live.                           |
| <i>AddressClass</i>  | Internet (IN).                          |
| <i>RecordType</i>    | Mail group member record ( <b>MG</b> ). |
| <i>MemberName</i>    | The login ID of the group member.       |

## Mail Exchanger Record

The mail exchanger (**MX**) records identify machines (gateways) that know how to deliver mail to a machine that is not directly connected to the network. This record is indicated by **MX** in the *RecordType* field. Wildcard names containing an \* (asterisk) can be used for mail routing with **MX** records. There may

be servers on the network that state that any mail to a domain is to be routed through a relay. The **MX** record is a valid entry in the **named.data** file. Its structure corresponds to the following format:

```
{Name} {TTL} AddressClass RecordType PrefValue MailExchanger
Ann.bus.com IN MX 0 Hamlet.Century.Com
*.dev.bus.com IN MX 0 Lear.Century.Com
```

## Fields

| Item                   | Description                                                                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Name</i>            | Specifies the full name of the host to which the mail exchanger knows how to deliver mail.                                                                                                                              |
|                        | <b>Note:</b> The * (asterisk) in the second <i>name</i> entry is a wildcard name entry. It indicates that any mail to the domain <i>dev.bus.com</i> should be routed through the mail gateway <i>Lear.Century.Com</i> . |
| <i>TTL</i>             | Time to live.                                                                                                                                                                                                           |
| <i>AddressClass</i>    | Internet (IN).                                                                                                                                                                                                          |
| <i>RecordType</i>      | Mail Exchanger ( <b>MX</b> ).                                                                                                                                                                                           |
| <i>PrefValue</i>       | Indicates the order the mailer should follow when there is more than one way to deliver mail to a host.                                                                                                                 |
| <i>MailerExchanger</i> | The full name of the mail gateway. See RFC 974 for more information.                                                                                                                                                    |

## Sysfiles File Format for BNU

### Purpose

Gives system administrators flexibility in configuring their **Systems**, **Devices** and **Dialers** files for use with BNU commands.

### Description

The **/etc/uucp/Sysfiles** file let system administrators specify alternate **Systems**, **Devices** and **Dialers** files to replace the default files in the **/etc/uucp** directory or to supplement those files to enable a separation of the data needed to access remote systems. It is organized so a user can invoke two distinct types of services, **uucico** and **cu**. The **uucico** service refers to the **/usr/sbin/uucp/uucico** command and the commands that invoke it, for example **uucp**, **uux**, **uusend**, **uucico**. It automatically logs into remote systems and sends and receives data. The **cu** service connects to remote systems without attempting to login and uses the **cu**, **ct**, and **slattach** commands to contact remote systems. The responses to the user name and password prompts as well as any data transfer is the responsibility of the user. Based upon these differences a system administrator can split the data used to contact remote systems according the service types

The **Sysfiles** file contains a description of each BNU service on the local system that can establish a remote connection. Each line in the **Sysfiles** file corresponds to the following syntax:

```
service=uucico|cu [systems=filename[:filename]] \
[devices=filename[:filename]] \
[dialers=filename[:filename]] \
```

If a service does not have a corresponding line in the **Sysfiles** file, the default files are used.

## Examples

1. A **Sysfiles** configuration that splits the configuration files for **uucico** and **cu** into different sets of files would be as follows:

```
service=uucico systems=Systems.cico devices=Devices.cico \
dialers=Dialers.cico
service=cu systems=Systems.cu devices=Devices.cu \
dialers=Dialers.cu
```

These two lines in a **Sysfiles** file state that two separate sets of **Systems**, **Devices** and **Dialers** files are used for each service. Each service is specified by the **service=** at the beginning of a line with no leading white space. The files used for each service is named on the same line according to the substrings appended to the **systems=**, **devices=** and **dialers=**. Their default location is in the **/etc/uucp** directory.

2. A configuration to split the **uucico** and **cu** service entries into separate files, but to combine common configuration data would be as follows:

```
service=uucico systems=Systems.cico:Systems \
devices=Devices.cico:Devices \
dialers=Dialers.cico:Dialers
service=cu systems=Systems.cu:Systems \
devices=Devices.cu:Devices \
dialers=Dialers.cu:Dialers
```

This example provides separate **Systems**, **Devices**, and **Dialers** files for each service, but combines any common data into the default files. As the example shows, multiple **Systems**, **Devices** and **Dialers** files can be specified for each service. A colon is used as the filename delimiter in such a case.

3. This example specifies separate **Systems** files for each service. Each service uses the default **Devices** and **Dialers** files.

```
service=uucico systems=Systems.cico
service=cu systems=Systems.cu
```

If no **Sysfiles** service entry is made for a **Systems**, **Devices**, or **Dialers** file, the default file is used. Any files specified in **Sysfiles** to serve as **Systems**, **Devices**, or **Dialers** files need to conform to the syntax used in the default files, **/etc/uucp/Systems**, **/etc/uucp/Devices** or **/etc/uucp/Dialers**.

## Files

| Item                      | Description                                                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>/etc/uucp</b>          | Contains all the default configuration files for BNU, including the <b>Sysfiles</b> file.                    |
| <b>/etc/uucp/Sysfiles</b> | Contains information about alternate <b>Systems</b> , <b>Devices</b> and <b>Dialers</b> files.               |
| <b>/etc/uucp/Systems</b>  | Lists and describes remote systems accessible to a local system, using the Basic Networking Utilities (BNU). |
| <b>/etc/uucp/Devices</b>  | Contains information about available devices.                                                                |
| <b>/etc/uucp/Dialers</b>  | Contains dialing sequences for various types of modems and other types of dialers.                           |

## Systems File Format for BNU

### Purpose

Lists and describes remote systems accessible to a local system, using the Basic Networking Utilities (BNU).

### Description

BNU Systems files, `/etc/uucp/Systems` by default, list the remote computers with which users of a local system can communicate using the Basic Networking Utilities (BNU) program. Other files specified in the `/etc/uucp/Sysfiles` file can be configured and BNU Systems files. Each entry in a **Systems** file represents a remote system, and users on the local system cannot communicate with a remote system unless that system is listed in the local **Systems** file. A **Systems** file must be present on every computer at your site that uses the BNU facility.

Each entry in a **Systems** file contains:

- Name of the remote system
- Times when users can connect to the remote system
- Type of link (direct line or modem link)
- Speed of transmission over the link
- Information needed to log in to the remote system

#### Note:

1. When a remote system not listed in a **Systems** file attempts to contact the remote system, the BNU program calls the `/usr/sbin/uucp/remote.unknown` shell procedure.
2. Only someone with root user authority can edit a **Systems** file, which is owned by the **uucp** program login ID.

### Fields in a Systems File

Each entry in a **Systems** file is a logical line containing fields and optional subfields. These fields appear in the following order:

*SystemName Time[;RetryTime] Type[,ConversationProtocol] Class Phone Login*

There must be an entry in every field of a line in a **Systems** file. If a field does not apply to the particular remote system (for example, a hardwired connection would not need a telephone number in the *Phone* field), use a - (minus sign) as a placeholder.

Lines in a **Systems** file cannot wrap. In addition, each entry must be on only one line in the file. However, a **Systems** file can contain blank lines and comment lines. Comment lines begin with a # (pound sign). Blank lines are ignored.

#### System Name

The *SystemName* field contains the name of the remote system. You can list an individual remote system in a **Systems** file more than once. Each additional entry for a system represents an alternate communication path that the BNU program uses in sequential order when trying to establish a connection between the local and the remote system.

#### Time

The *Time* field contains a string that indicates the days of the week and the times of day during which users on the local system can communicate with the specified remote system. For example, the MoTuTh0800-1730 string indicates that local users can contact the specified remote system on Mondays, Tuesdays, and Thursdays from 8 a.m. until 5:30 p.m.

The day part of the entry can be a list including any day or days represented by Mo, Tu, We, Th, Fr, Sa, or Su. The day entry may also be Wk if users can contact the remote system on any weekday, or Any if they can use the remote system on any day of the week including Saturday and Sunday.

Enter the time at which users can contact the remote system as a range of times, using the 24-hour clock notation. For example, if users can communicate with the specified remote system only during the morning hours, type a range such as 0800-1200. If users can contact the remote computer at any time of day or night, simply leave the time range blank.

It is also possible to specify times during which users cannot communicate with the remote system by specifying a time range that spans 0000. For example, typing 0800-0600 means that users can contact the specified system at any time *except* between 6 a.m. and 8 a.m. This is useful if a free line is needed at a certain time of day in order to use the remote system for administrative purposes.

If the remote system calls the local system, but users on the local system cannot call the remote system, the time entry may be Never.

Multiple *Time* fields are separated by a , (comma). For example, Wk1800-0600,Sa,Su means that users can contact the remote system on any weekday at any time except between the hours of 6 p.m. and 6 a.m. and at any time on Saturday and Sunday.

### **RetryTime Subfield**

The *RetryTime* subfield is an optional subfield that specifies the minimum time in minutes between an unsuccessful attempt to reach the remote system and the retry time when the BNU program again attempts to communicate with that system. This subfield is separated from the rest of the string by a ; (semicolon). For example, Wk1800-0600,Sa,Su;2 indicates that if the first attempt to establish communications fails, BNU should continue to attempt to contact the remote system at no less than 2-minute intervals.

#### **Note:**

1. This subfield, when present, overrides the default retry time of 5 minutes.
2. The retry time does *not* cause BNU to attempt contact with the system once the time has elapsed. It specifies the *minimum* time BNU must wait before attempting to contact the remote system.

### **Type**

The *Type* field identifies the type of connection used to communicate with the remote system. The available types of connections are ACU for a telephone connection using a modem, the remote system name (as in the *SystemName* field) for a hardwired connection, and TCP for a connection using TCP/IP. There must be a corresponding entry for the type of connection in either the **/etc/uucp/Devices** file or the **Devices** file specified in the **/etc/uucp/Sysfiles** file.

### **Conversation Protocol Subfield**

If you use the TCP entry in the *Type* field, the *ConversationProtocol* subfield, associated with the caller, specifies a conversation protocol. The default is the g protocol. To use a different subfield, enter a , (comma) and the letter representing one of the other conversation protocols, either t or e. These protocols are faster and more efficient than the g protocol.

| <b>Protocol</b> | <b>Explanation</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>g</b>        | This is the default. The <b>g</b> protocol is preferred for modem connections, but it involves a large overhead in running BNU commands because it uses the checksumming and packetizing functions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>t</b>        | The <b>t</b> protocol presumes an error-free channel and is essentially the <b>g</b> protocol without the checksumming and packetizing functions. Use the <b>t</b> protocol: <ul style="list-style-type: none"> <li>• To communicate with a site running the operating system version of the BNU program</li> <li>• To communicate with a site running the Berkeley version of the UNIX-to-UNIX Copy Program (UUCP).</li> </ul>                                                                                                                                                                                                                                                                                                                                        |
| <b>e</b>        | The <b>t</b> protocol cannot be used when the <i>Type</i> field is ACU or when a modem connection is being used.<br>Use the <b>e</b> protocol: <ul style="list-style-type: none"> <li>• To communicate with a site running the BNU program on</li> <li>• To communicate with a site running the operating system version of the BNU program.</li> </ul> The <b>e</b> protocol is not reliable for modem connections.<br><br>Use either the <b>t</b> or <b>e</b> protocol to communicate with a site running the operating system version of the BNU program. Use the <b>e</b> protocol for a site running a non-operating system version of the BNU program. Use the <b>t</b> protocol for sites running the Berkeley version of the UNIX-to-UNIX Copy Program (UUCP). |

## Class

The *Class* field typically specifies the speed at which the specified hardwired or telephone line transmits data. It is generally 300, 1200, 2400, or higher for a hardwired device, and 300, 1200, or 2400 for a telephone connection.

This field can also contain a letter with a speed (for example, C1200, D1200) to differentiate between classes of dialers. For example, some offices have more than one telephone network, one for internal use and one for external communications. In such a case, it is necessary to distinguish which lines should be used for each connection.

If the entry in the *Type* field is ACU, the *Class* field in a **Systems** file is matched against the *Class* field in a **Devices** file to find the device to use for connections. For example, if a **Systems** file entry for system here is:

```
hera Any ACU 1200 3-3-5-2 oгин: nuucp ssword: oldoaktree
```

BNU searches for an entry in the **Devices** file with a *Type* of ACU and a *Class* of 1200 and connects to system hera using the first available device that meets these specifications.

If the device can match any speed, enter the word Any in the *Class* field. Note that the word Any begins with an uppercase A.

Do not include a transmission rate for a TCP/IP connection. If you do not type a transmission rate in the *Class* field, use a - (minus sign) as a placeholder.

## Phone

For a telephone connection over a modem, the *Phone* field specifies the telephone number used to reach the remote modem. If this entry represents a hardwired connection, type a - (minus sign) as a placeholder. If this entry represents a telephone connection using a modem, type the remote modem's phone number.

The *Phone* field for a telephone connection must include all of the following items that apply, in the following order:

1. Outside line code
2. Long-distance access codes
3. Number 1 (one) plus the area code (if the modem is out of the local area)

4. Three-digit exchange number
5. Four-digit modem number

Entering a complete phone number is the most efficient method of including phone numbers if your site uses only a relatively small number of telephone connections. However, if your site includes a large number of remote connections established using a phone line and a modem, you may prefer to use the **/etc/uucp/Dialcodes** file to set up dial-code abbreviations.

For example, if your site communicates regularly using modems to other systems at the same remote site, it is more efficient to use a dial-code abbreviation in a **Systems** file than to type the complete phone number of each remote modem.

The dial-code entry in the **/etc/uucp/Dialcodes** file defines an alphabetic abbreviation that represents the following portions of the phone number:

- Outside line code
- Long-distance access code
- Number 1 (one) plus the area code (if the modem is out of the local area)
- Three-digit exchange number

In the *Phone* field in a **Systems** file entry, type the alphabetic abbreviation followed by the four-digit modem number.

**Note:** Enter the alphabetic abbreviation in the **/etc/uucp/Dialcodes** file *only once* for all the remote modems listed in a **Systems** file. Then use the same abbreviation for all entries in a **Systems** file for modems at that site.

For callers that are actually switches, the *Phone* field is the token the switch requires to get to the particular computer. The token you enter here is used by the functions specified in the *Type* field of the **/etc/uucp/Dialcodes** file.

## Login

The *Login* field specifies login information that the remote system must receive before allowing the calling local system to establish a connection. The *Login* field is a series of fields and subfields called *expect-send* characters.

### Expect-Send Characters in Login Fields

Enter the required login information as:

*[Expect Send] ...*

The *Expect* subfield contains characters that the local system expects to receive from the remote system. Once the local system receives those characters, it sends another string of characters that comprise the *Send* subfield.

For example, the first *Expect* subfield generally contains the remote system's login prompt, and the first *Send* subfield generally contains the remote system login ID. The second *Expect* subfield contains the remote password prompt, and the second *Send* subfield contains the remote system password.

The *Expect* subfield may include subfields entered in the following form:

*Expect [-Send-Expect] ...*

In this case, the first *Expect* subfield still represents the string that the local system expects to receive from the remote system. However, if the local system does not receive (or cannot read) the first *Expect* string, it

sends its own string (the *Send* string within brackets) to the remote system. The local system then expects to receive another *Expect* string from the remote system.

For example, the *Expect* string may contain the following characters:

`login:--login:`

The local system expects to receive the `login:` string. If the remote system sends that string and the local system receives it correctly, the BNU program goes on to the next field in the expect-send sequence. However, if the local system does not receive the `login:` string, it sends a null character followed by a new line, and then expects to receive a second `login:` string from the remote computer.

If the remote system does not send an *Expect* string to the local system, type "" (two double quotation marks), representing a null string, in the first *Expect* subfield.

Every time the local system sends a field, it automatically transmits a new line following that *Send* subfield. To disable this automatic new line, type `\c` (backslash and the letter c) as the last two characters in the *Send* string.

Two special strings can be included in the login sequence. The EOT string sends an ASCII EOT (end of transmission) character, and the BREAK string attempts to send an ASCII BREAK character.

### Valid Expect-Send Sequences

Following are the valid expect-send strings for the *Login* field:

| String             | Explanation                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\N</code>    | Null character.                                                                                                                             |
| <code>\b</code>    | Backspace character.                                                                                                                        |
| <code>\c</code>    | At the end of a field, suppress the new line that normally follows the characters in a <i>Send</i> subfield. Otherwise, ignore this string. |
| <code>\d</code>    | Delay 2 seconds before sending or reading more characters.                                                                                  |
| <code>\p</code>    | Pause for approximately .25 to .50 seconds.                                                                                                 |
| <code>\E</code>    | Turn on the echo check.                                                                                                                     |
| <code>\e</code>    | Turn off the echo check.                                                                                                                    |
| <code>\K</code>    | Send a BREAK character. This is the same as entering BREAK. This character can be used to cycle a modem's speed.                            |
| <code>\n</code>    | New-line character.                                                                                                                         |
| <code>\r</code>    | Carriage return.                                                                                                                            |
| <code>\s</code>    | Space character.                                                                                                                            |
| <code>\t</code>    | Tab character.                                                                                                                              |
| <code>\\"</code>   | Backslash character.                                                                                                                        |
| <code>EOT</code>   | EOT character. When you enter this string, the system sends two EOT new-line characters.                                                    |
| <code>BREAK</code> | BREAK character. This character can be used to cycle the modem speed.                                                                       |
| <code>\ddd</code>  | Collapse the octal digits (ddd) into a single character and send that character.                                                            |

### Using the BREAK Character to Cycle a Modem

A BREAK or `\K` character is usually sent to cycle the line speed on computers that have a multispeed modem. For example, if you are using a 2400 baud modem to contact a remote system with a multi speed modem that normally answers the phone at 9600 baud, you can begin the chat script for that system with a `\K` character to cause the remote system modem to cycle down to 2400 baud.

### Entries for Use with TCP/IP

If your site is using TCP/IP, include the relevant TCP/IP entries in a **Systems** file. For a remote system connected to the local system using TCP/IP, the entries in the *SystemName*, *Time*, and *Login* fields are the same as for a remote system using any other type of connection. For the *Type* field, decide on the appropriate TCP/IP conversation protocol to enter in the *TCP ConversationProtocol* subfield. Enter TCP

followed by a ,(comma) followed by the letter representing the protocol. In the *Class* and *Phone* fields, enter a - (minus sign) as a placeholder.

## Examples

### Setting Up Entries Using Modems

1. A standard entry for a telephone connection using a modem looks like this:

```
merlin 0830-1730 ACU 1200 123-4567 in:--in: uucp1 word: rainday
```

This entry allows users to contact system *merlin* daily between 8:30 a.m. and 5:30 p.m., using an ACU at 1200 bps. The telephone number is 123-4567. The login name on *merlin* is *uucp1* and the password is *rainday*. The local system expects the phrase *in:* before it sends the login name. If the local system does not receive the phrase *in:*, it sends a null character and a new-line character and expects the phrase again.

2. To use a 1200 baud modem to contact a system with a multispeed modem, make an entry similar to the following:

```
athena Any ACU 1200 123-7654 \K\K in:--in: uucpa word: shield
```

The \K prefacing the login script instructs the remote modem to cycle down one speed. If the modem has three speeds, 9600, 2400, and 1200, the first \K character causes it to cycle to the 2400 baud setting, and the second \K character causes it to use the 1200 baud setting. (A third \K causes the modem to start the cycle over by returning to 9600 baud.)

### Setting Up Entries Using Direct Connections

A standard entry for a hardwired connection between a local and a remote system looks like this:

```
hera Any hera 1200 - login:--login: uzeus word: thunder
```

The remote system is *hera*, which can be called at any time. The entry in the *Type* field is also *hera*, indicating a directory connection at 1200 bps (the *Class* field). There is a placeholder in the *Phone* field since no telephone number is necessary.

### Setting Up Entries Using TCP/IP Connections

In order to make the appropriate entries in a **Systems** file, decide on the appropriate TCP/IP conversation protocol to enter in the TCP *Caller* subfield. For example, enter the following in a **Systems** file to use TCP/IP to connect to system *venus* with the default *g* protocol:

```
venus Any TCP - - in:--in: uzeus word: lamplight
```

Replace the *send* and *expect* characters in the sample login field with the login prompt, login, password prompt, and password appropriate to the remote system for which you are establishing a connection.

### Using Dialcode Abbreviations

To use a dialcode abbreviation defined in the */etc/uucp/Dialcodes* file, enter the following in a **Systems** file:

```
merlin Any ACU 1200 local8784 in:--in: uucp1 word: magic
```

This assumes that an entry for the dial code *local* exists in the **Dialcodes** file. For example, the following entry:

```
local 9=445
```

in the **Dialcodes** file would cause BNU to expand the telephone number as 9=4458784.

### Setting Up Entries for Both Local and Remote Systems

For a direct connection between two systems, a **Systems** file on system **zeus** contains the following entry for the remote system **hera**:

```
hera Any hera 1200 - "" \r\d\r\d\r in:--in: uzeus word: thunder
```

A **Systems** file on system **hera** contains the following entry for system **zeus**:

```
zeus Any zeus 1200 - "" \r\d\r\d\r in:--in: uhera word: lostleaf
```

## Files

| Item                               | Description                                                                    |
|------------------------------------|--------------------------------------------------------------------------------|
| /etc/uucp directory                | Contains all the configuration files for BNU, including a <b>Systems</b> file. |
| /etc/uucp/Sysfiles file            | Specifies possible alternative foles for the /etc/uucp/Systems file.           |
| /etc/uucp/Devices file             | Contains information about available devices.                                  |
| /etc/uucp/Dialcodes file           | Contains dialing code abbreviations.                                           |
| /etc/uucp/Permissions file         | Describes access permissions for remote systems.                               |
| /usr/sbin/uucp/remote.unknown file | Records contacts from unknown systems.                                         |

## telnet.conf File Format for TCP/IP

### Purpose

Translates a client's terminal-type strings into **terminfo** file entries.

### Description

The **telnetd** daemon uses the **/etc/telnet.conf** file during terminal negotiation to translate a client's terminal-type strings into **terminfo** file entries. The **telnet.conf** file is used when a client's terminal does not correspond directly to a **terminfo** file entry. If this is the case, the **telnet.conf** file can map standard terminal names (defined in RFC-1060 Assigned Numbers) to **terminfo** file entries that the system can emulate.

Each line in the **telnet.conf** file can contain up to 255 characters. Lines beginning with a # (pound sign) are comment lines.

The **telnet.conf** file is structured in a two-column line format, with dashes separating the items in each column. The first column specifies a manufacturer, model type, and optional additional information. The second column specifies the **terminfo** file entry that corresponds to the manufacturer, model, and optional information in the first column. The items in the first column can be either uppercase or lowercase. The items in the second column must be lowercase. RFC-1060 specifies the first terminal type in the **telnet.conf** file. The format for the **telnet.conf** file is:

Manufacturer-Model-Options TerminfoModel-Options

### Security

Suggested permissions for the **telnet.conf** file are **rw-rw-r-** or **664**. Suggested ownership is **root** for owner and **system** for group.

## Examples

Sample **telnet.conf** entries might look like the following:

```
DEC-VT100-AM vt100-am
diablo-1620-m8 1620-m8
h-19-a 19-a
TI-800 ti-800
```

In the first entry, the manufacturer is DEC (Digital Equipment Corporation), the model is VT100, and the AM option specifies automargin. In the second entry, the manufacturer is diablo, the model is 1620, and the m8 option specifies a left margin of 8 columns. In the third entry, the manufacturer is h (Heath), the model is 19, and the a option specifies ANSI mode. In the fourth entry, the manufacturer is TI (Texas Instruments), and the model is 800; no options are specified. For additional **terminfo** options, refer to the \*.ti files in the **/usr/lib/terminfo** directory.

## Files

| Item            | Description                       |
|-----------------|-----------------------------------|
| <b>terminfo</b> | Describes terminal by capability. |

## **tempaddr.conf** File Format for TCP/IP

### Purpose

Defines if temporary addresses should be allowed or denied for a set of prefixes or for a particular interface.

### Available Directives

The main directives for the **/etc/ndpd/tempaddr.conf** file is:

### Syntax

**<allow | deny> all**

This directive tells whether temporary addresses should/should not be generated for the prefixes not mentioned in tempaddr.conf.

**<allow | deny> <interface> all**

This directive tells whether temporary addresses should or should not be generated for all the prefixes on the specified interface.

**<allow | deny> <interface> <prefix>/ <prefix length>**

This directive tells whether temporary addresses should/should not be generated for the prefix/list of prefixes on the specified interface. Multiple prefixes and prefix lengths are separated by comma (,). Most recent entry in the **tempaddr.conf** file will override the older entries while generating temporary addresses.

## Files

| Item                             | Description                                    |
|----------------------------------|------------------------------------------------|
| /usr/samples/tcpip/tempaddr.conf | Contains the sample <b>tempaddr.conf</b> data. |

## **tepolicies.dat File Format**

### **Purpose**

Contains trusted execution policies for the system.

### **Description**

The **/etc/security/tsd/tepolicies.dat** file is a configuration file where the system wide trusted execution policies are defined. The trusted execution policies can be configured using the following policies:

```
TE=ON
CHKEXEC=ON
CHKSHLIB=OFF
CHKSCRIPT=OFF
CHKKERNEXT=OFF
STOP_UNTRUSTD=OFF
STOP_ON_CHKFAIL=OFF
LOCK_KERN_POLICIES=OFF
TSD_FILES_LOCK=OFF
TSD_LOCK=OFF
TEP=OFF
TEP=/usr/bin:/usr/sbin:/etc:/bin:/sbin:/bin/helpers/jfs2:/usr/lib/instl:/usr/ccs/bin
TLP=OFF
TLP=/usr/lib:/usr/ccs/lib:/lib:/var/lib
```

The description of each configuration parameter and more details of the trusted execution can be found in the Security policies configuration topic.

“/etc/nscontrol.conf File” on page 175

## **terminfo Directory**

### **Purpose**

Contains compiled **terminfo** source files.

### **Description**

**Terminfo** is a compiled database describing the capabilities of terminals. Terminals are described in the **terminfo** source files via entries. Each entry contains information about the capabilities for a particular terminal or set of common terminals. Capabilities include the operations that can be performed, the padding requirements, cursor positioning, command sequences, and initialization sequences.

The compiled **terminfo** database is used by applications such as curses and vi that must have knowledge of the terminal but do not want to be terminal-dependent.

An example of a **terminfo** source file is provided.

This article explains the **terminfo** source file format. Before a **terminfo** description can be used by applications, the **terminfo** source file it resides in must be compiled using the **tic** command. Using the **tic** command results in the creation of one or more binaries, one for each terminal. The collection of **terminfo** binaries in a directory (usually **/usr/share/lib/terminfo**) is known as the **terminfo** database, or **terminfo**.

## Source File Entries

You can edit or modify source files. A source file can contain one or more terminal descriptions or entries. A **terminfo** source file has a **.ti** suffix. Examples of source files are the **/usr/share/lib/terminfo/ibm.ti** file, which describes IBM terminals, and the **/usr/share/lib/terminfo/dec.ti** file, which describes DEC terminals.

See the **infocmp** command for obtaining the source description for a terminal when only the binary is available.

Each entry in a **terminfo** source file consists of a number of fields separated by commas. White space between commas is ignored. The following example shows a source file entry:

```
ibm6155-113|IBM 6155 Black & White display,
 font0=\E[10m, font1=\E[11m, font2=\E[12m,
 bold=\E[12m, sgr0=\E[0;10m,
 cols#113, lines#38,
 sgr=\E[%?%p1%t;7%;%?%p2%t;4%;%?%p3%t;7%;%?%p4%t;5%;%?%p6%t;12%;m,
 blink@, use=ibm5151,
```

Entries can continue onto multiple lines by placing white space at the beginning of each subsequent line. To create a comment line, begin the line with a # (pound sign) character. To comment out an individual terminal capability, put a period before the capability name.

The first field (or line) for each terminal gives the various names by which the terminal is known, separated by | (pipe symbol) characters. The first given name should be the most common abbreviation for the terminal. (This name is the one most commonly used when setting the TERM environment variable.) The last name given should be a long name fully identifying the terminal. All other names are understood as synonyms for the terminal name. All names but the last should contain no blanks. The last name may contain blanks for readability. All names should be unique.

The remaining fields identify the terminal's capabilities.

When choosing terminal names, there are some conventions you should follow. The root name should represent the particular hardware class of the terminal. Do not use hyphens in the root name, except to avoid synonyms that conflict with other names. To indicate possible modes for the hardware or user preferences, append a - (minus sign) and one of the following suffixes:

*Table 6. Root Name Suffixes*

| Suffix | Meaning                                  | Example             |
|--------|------------------------------------------|---------------------|
| -am    | With automatic margins (usually default) | <i>Terminal-am</i>  |
| -m     | Monochrome mode                          | <i>Terminal-m</i>   |
| -w     | Wide mode (more than 80 columns)         | <i>Terminal-w</i>   |
| -nam   | Without automatic margins                | <i>Terminal-nam</i> |
| -n     | Number of lines on the screen            | <i>Terminal-60</i>  |
| -na    | No arrow keys (leave them in local)      | <i>Terminal-na</i>  |
| -np    | Number of pages of memory                | <i>Terminal-4p</i>  |
| -rv    | Reverse video                            | <i>Terminal-rv</i>  |

*Table 6. Root Name Suffixes (continued)*

| Suffix      | Meaning                                                                                                                                                                                                                                                                       | Example             |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| <b>-s</b>   | Status line simulation. The terminal allows for one or more lines that are normally part of the screen to be used for the status line. This is not the same as terminals that have permanently dedicated status lines.                                                        | <i>Terminal-s</i>   |
| <b>-unk</b> | Unknown mode. This entry can be used to define a general description of a terminal that has several of the modes described above. The other entries would use the unknown entry as a base description and add the appropriate customization. See the <code>use=</code> field. | <i>Terminal-unk</i> |

A terminal in 132-column mode would be *Terminal-w*.

## Types of Capabilities

A **terminfo** entry can define any number of capabilities. All capabilities belong to one of three types:

| Item    | Description                                                                                                                                             |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Boolean | Indicates that the terminal has a particular feature. Boolean capabilities are true if the corresponding name is contained in the terminal description. |
| Numeric | Gives the size of the terminal or the size of particular delays.                                                                                        |
| String  | Gives a sequence that can be used to perform particular terminal operations.                                                                            |

This article provides tables that document the capability types. All the tables list the following:

| Item        | Description                                                                                                                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Variable    | The name the application uses to access a capability.                                                                                                                                                                                           |
| Cap Name    | The short capability name. This name is used in the <b>terminfo</b> database text and by the person creating or editing a source file entry. You can use the <b>tput</b> command to output the value of a capability for a particular terminal. |
| I.Code      | The 2-letter internal code used in the compiled database. This code always corresponds to a <b>termcap</b> capability name.                                                                                                                     |
| Description | A description of the capability.                                                                                                                                                                                                                |

Capability names have no absolute length limit. An informal limit of five characters is adopted to keep them short and to allow the tabs in the caps source file to be aligned. Whenever possible, names are chosen to be the same as or similar to the ANSI X3.64 standard of 1979.

## Boolean Capabilities

A Boolean capability indicates that the terminal has some particular feature. For instance, the **am** capability in a terminal description indicates that the terminal has automatic margins (such as an automatic new line when the end of a line is reached). The following are the Boolean capabilities:

*Table 7. Boolean Capabilities*

| Variable                                                                                                                        | Cap Name | I.Code |
|---------------------------------------------------------------------------------------------------------------------------------|----------|--------|
| <b>auto_left_margin</b><br>Indicates <b>cub1</b> wraps from column 0 to last column.                                            | bw       | bw     |
| <b>auto_right_margin</b><br>Indicates terminal has automatic margins.                                                           | am       | am     |
| <b>back_color_erase</b><br>Erases screen with current background.                                                               | bce      | ut     |
| <b>can_change</b><br>Can redefine existing color.                                                                               | ccc      | cc     |
| <b>ceol_standout_glitch</b><br>Indicates that standout is not erased by overwriting.                                            | xhp      | xs     |
| <b>col_addr_glitch</b><br>Indicates only positive motion for hpa/mhp caps.                                                      | xhpa     | YA     |
| <b>cpi_changes_res</b><br>Indicates resolution changed when changing character pitch.                                           | cpix     | YF     |
| <b>cr_cancels_micro_mode</b><br>Indicates cr turns off micro mode.                                                              | crxm     | YB     |
| <b>dest_tabs_magic_sms0 (or teleray_glitch)</b><br>Indicates destructive tabs and blanks inserted while entering standout mode. | xt       | xt     |
| <b>eat_newline_glitch</b><br>Ignores new-line character after 80 columns.                                                       | xenl     | xn     |
| <b>erase_overstrike</b><br>Erases overstrikes with a blank.                                                                     | eo       | eo     |
| <b>generic_type</b><br>Indicates generic line type, such as, dialup or switch.                                                  | gn       | gn     |
| <b>hard_copy</b><br>Indicates hardcopy terminal.                                                                                | hc       | hc     |
| <b>hard_cursor</b><br>Indicates cursor is hard to see.                                                                          | chits    | HC     |
| <b>has_meta_key</b><br>Indicates terminal has a meta key, such as shift or sets parity bit.                                     | km       | km     |
| <b>has_print_wheel</b><br>Indicates operator needed to change character set.                                                    | daisy    | YC     |
| <b>has_status_line</b><br>Indicates terminal has a dedicated status line.                                                       | hs       | hs     |
| <b>hue_lightness_saturation</b><br>Uses HLS color notation (Tektronix).                                                         | hls      | hl     |
| <b>insert_null_glitch</b><br>Indicates insert mode distinguishes nulls.                                                         | in       | in     |
| <b>lpi_changes_res</b><br>Indicates resolution changed when changing line pitch.                                                | lpix     | YG     |
| <b>memory_above</b><br>Display retained above the screen (usually multi-page terminals).                                        | da       | da     |

*Table 7. Boolean Capabilities (continued)*

| Variable                                                                                     | Cap Name | I.Code |
|----------------------------------------------------------------------------------------------|----------|--------|
| <b>memory_below</b><br>Display retained below the screen (usually multi-page terminals)      | db       | db     |
| <b>move_insert_mode</b><br>Indicates safe to move while in insert mode.                      | mir      | mi     |
| <b>move_standout_mode</b><br>Indicates safe to move in standout modes.                       | msgr     | ms     |
| <b>needs_xon_xoff</b><br>Indicates padding will not work, that xon/xoff is required.         | nxon     | nx     |
| <b>no_esc_ctlc (or beehive_glitch)</b><br>Indicates a terminal with F1=escape and F2=Ctrl-C. | xsb      | xb     |
| <b>no_pad_char</b><br>Indicates pad character does not exist.                                | npc      | NP     |
| <b>non_dest_scroll_region</b><br>Indicates non-destructive scrolling region.                 | ndscr    | ND     |
| <b>non_rev_rmcup</b><br>Indicates smcup does not reverse rmcup.                              | nrrmc    | NR     |
| <b>over_strike</b><br>Indicates terminal overstrikes.                                        | os       | os     |
| <b>ptr_silent</b><br>Indicates printer will not echo on screen.                              | mc5i     | 5i     |
| <b>row_addr_glitch</b><br>Indicates only positive motion for vpa/mvpa caps.                  | xvpa     | YD     |
| <b>semi_auto_right_margin</b><br>Indicates printing in last column causes carriage return.   | sam      | YE     |
| <b>status_line_esc_ok</b><br>Indicates escape can be used on the status line.                | eslok    | es     |
| <b>tilde_glitch</b><br>Indicates terminal cannot print the ~ (tilde) character.              | hz       | hz     |
| <b>transparent_underline</b><br>Overstrikes with underline character.                        | ul       | ul     |
| <b>xon_xoff</b><br>Indicates terminal uses xon/xoff handshaking.                             | xon      | xo     |

## Numeric Capabilities

Numeric capabilities are followed by the # (pound sign) character and a numeric value. The **cols#80** capability indicates the terminal has 80 columns. The following are the numeric capabilities:

*Table 8. Numeric Capabilities*

| Variable                                                                                                                               | Cap Name | I.Code |
|----------------------------------------------------------------------------------------------------------------------------------------|----------|--------|
| <b>buffer_capacity</b><br>Specifies the number of bytes buffered before printing.                                                      | bufsz    | Ya     |
| <b>columns</b><br>Specifies the number of columns in a line.                                                                           | cols     | co     |
| <b>dot_horz_spacing</b><br>Identifies the horizontal spacing of dots in dots per inch.                                                 | spinh    | Yc     |
| <b>dot_vert_spacing</b><br>Specifies vertical spacing of pins in pins per inch.                                                        | spinv    | Yb     |
| <b>init_tabs</b><br>Provides initial tabs every specified number of spaces.                                                            | it       | it     |
| <b>label_height</b><br>Specifies the number of rows in each label.                                                                     | lh       | lh     |
| <b>label_width</b><br>Specifies the number of columns in each label.                                                                   | lw       | lw     |
| <b>lines</b><br>Specifies the number of lines on screen or page.                                                                       | lines    | li     |
| <b>lines_of_memory</b><br>Specifies the number of lines of memory if > lines. A value of 0 indicates a variable number.                | lm       | lm     |
| <b>magic_cookie_glitch</b><br>Indicates number of blank characters left by <b>sms0</b> or <b>rms0</b> .                                | xmc      | sg     |
| <b>max_attributes</b><br>Identifies the maximum combined video attributes the terminal can display.                                    | ma       | ma     |
| <b>max_colors</b><br>Specifies the maximum number of colors supported.                                                                 | colors   | Co     |
| <b>max_micro_address</b><br>Indicate the limit on use of <b>mhp0</b> and <b>mvp0</b> .                                                 | maddr    | Yd     |
| <b>max_micro_jump</b><br>Specifies the limit on use of the <b>mcub1</b> , <b>mcuf1</b> , <b>mcuu1</b> , and <b>mcud1</b> capabilities. | mjump    | Ye     |
| <b>max_pairs</b><br>Specifies the maximum number of color pairs supported.                                                             | pairs    | pa     |
| <b>maximum_windows</b><br>Specifies the maximum number of defineable windows.                                                          | wnum     | MW     |
| <b>micro_char_size</b><br>Specifies the character step size when in micro mode.                                                        | mcs      | Yf     |
| <b>micro_line_size</b><br>Identifies the line step size when in micro mode.                                                            | mls      | Yg     |
| <b>no_color_video</b><br>Indicates video attributes that cannot be used with colors.                                                   | ncv      | NC     |
| <b>num_labels</b><br>Specifies the number of labels on the screen. This value starts at 1.                                             | nlab     | Nl     |

*Table 8. Numeric Capabilities (continued)*

| Variable                                                                                                        | Cap Name | I.Code |
|-----------------------------------------------------------------------------------------------------------------|----------|--------|
| <b>number_of_pins</b><br>Identifies the number of pins in the print-head.                                       | npins    | Yh     |
| <b>output_res_char</b><br>Specifies the horizontal resolution in units per character.                           | orc      | Yi     |
| <b>output_res_horz_inch</b><br>Specifies the horizontal resolution in units per inch.                           | orhi     | Yk     |
| <b>output_res_line</b><br>Specifies the vertical resolution in units per line.                                  | orl      | Yj     |
| <b>output_res_vert_inch</b><br>Indicates vertical resolution in units per inch.                                 | orvi     | Yl     |
| <b>padding_baud_rate</b><br>Indicates lowest baud rate where carriage-return and line-return padding is needed. | pb       | pb     |
| <b>print_rate</b><br>Indicates print rate in characters per second.                                             | cps      | Ym     |
| <b>virtual_terminal</b><br>Indicates virtual terminal number.                                                   | vt       | vt     |
| <b>wide_char_size</b><br>Identifies the character step size when the terminal is in double-wide mode.           | widcs    | Yn     |
| <b>width_status_lines</b><br>Specifies the number of columns in status lines.                                   | wsl      | ws     |

## String Capabilities

You define string-valued capabilities, such as the **el** capability (clear to end of line) with a 2-character code, an = (equal sign), and a string ending with a , (comma). A delay in milliseconds can appear anywhere in a string capability. To define a delay, enclose the delay between a \$< and a >. The following shows the **el** capability with a delay of 3:

```
el=\EK$<3>
```

The **tputs** subroutine provides padding characters for a delay. A delay can be a number, such as 20, or a number followed by an \* (asterisk), such as 3\*. An asterisk indicates that the required padding is proportional to the number of lines affected by the operation. The number given represents the required padding for each affected unit. (For insert character, the factor is the number of lines affected, which is always 1, unless the terminal has the **xenl** capability and the software supports it). If you specify an asterisk, it is sometimes useful to give a delay of the form *a.b*, such as 3.5, to specify a delay for each unit to tenths of milliseconds. You can only specify one decimal place.

The **terminfo** database provides several escape sequences in the string-valued capabilities for easy encoding of characters. The following escape codes are recognized:

| Escape Code | Meaning                                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------|
| \E,\e       | Escape                                                                                                                    |
| \n          | New line                                                                                                                  |
| \l          | Line feed                                                                                                                 |
| \r          | Carriage return                                                                                                           |
| \t          | Tab                                                                                                                       |
| \b          | Backspace                                                                                                                 |
| \f          | Form feed                                                                                                                 |
| \s          | Space                                                                                                                     |
| \^          | Caret                                                                                                                     |
| \\\         | Backslash                                                                                                                 |
| \,          | Comma                                                                                                                     |
| \:          | Colon                                                                                                                     |
| \nnn        | Character with octal value <i>nnn</i>                                                                                     |
| \^x         | Ctrl-x for any appropriate x                                                                                              |
| \0          | Null character. \0 actually produces \200, which does not end a string but behaves as a null character on most terminals. |

The following conventions are used in the String Capabilities table:

- (G) Indicates that the string is passed through **tparm**, with parameters as given (#i).
- (\*) Indicates that padding can be based on the number of lines affected.
- (#i) Indicates the *i*th parameter.

*Table 9. String Capabilities*

| Variable                                                                    | Cap Name | I.Code |
|-----------------------------------------------------------------------------|----------|--------|
| <b>appl_defined_str</b><br>Application-defined terminal string.             | apstr    | za     |
| <b>asc_chars</b><br>Alternate character set mapping of glyph to characters. | acsc     | ac     |
| <b>back_tab</b><br>Back tab.                                                | cbt      | bt     |
| <b>bell</b> Produces an audible signal (bell).                              | bel      | bl     |
| <b>box_chars_1</b><br>Box characters, primary set.                          | box1     | bx     |
| <b>box_chars_2</b><br>Box characters, alternate set.                        | box2     | by     |
| <b>box_attr_1</b><br>Attributes for box_chars_1.                            | batt1    | Bx     |

| <b>up_half_line</b><br>Indicates superscript (reverse 1/2 line-feed)                | hu       | hu     |
| <b>user0</b> User string 0.                                                         | u0       | u0     |
| <b>user1</b> User string 1.                                                         | u1       | u1     |
| <b>user2</b> User string 2.                                                         | u2       | u2     |
| <b>user3</b> User string 3.                                                         | u3       | u3     |
| <b>user4</b> User string 4.                                                         | u4       | u4     |
| <b>user5</b> User string 5.                                                         | u5       | u5     |
| <b>user6</b> User string 6.                                                         | u6       | u6     |
| <b>user7</b> User string 7.                                                         | u7       | u7     |
| <b>user8</b> User string 8.                                                         | u8       | u8     |
| <b>user9</b> User string 9.                                                         | u9       | u9     |
| <b>wait_tone</b><br>Wait for dial tone.                                             | wiat     | WA     |

Table 9. String Capabilities (continued)

| Variable                                                      | Cap Name | I.Code |
|---------------------------------------------------------------|----------|--------|
| <b>xoff_character</b><br>X-off character.                     | xoffc    | XF     |
| <b>xon_character</b><br>X-on character.                       | xonc     | XN     |
| <b>zero_motion</b><br>No motion for the subsequent character. | zerom    | Zx     |

## Preparing Descriptions

You can create a terminal description by copying and then modifying the description of a similar terminal. You can check the accuracy of your partial descriptions with the vi editor. Some terminals may reveal bugs in the vi editor as well as deficiencies in the ability of the **terminfo** database to provide a terminal description.

To test a new terminal description, set the **TERMINFO** environment variable to the path name of the directory containing the compiled description on which you are working. Programs then check that directory instead of the **/usr/share/lib/terminfo** directory.

To test for correct padding (if known), do the following:

1. Edit the **/etc/passwd** file at 9600 baud.
2. Delete about 16 lines from the middle of the screen.
3. Press the u key several times quickly.

If the terminal fails to display the result properly, more padding is usually needed. You can perform a similar test for insert character.

**Note:** Excessive padding slows down the terminal.

## Basic Capabilities

This section describes some basic terminal capabilities. If a terminal supports one of these capabilities, the terminal's **terminfo** source file entry indicates it. The following list is a list of basic capabilities:

| Item         | Description                                                                                                                                                                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>am</b>    | Indicates that the cursor moves to the beginning of the next line when it reaches the right margin. This capability also indicates whether the cursor can move beyond the bottom right corner of the screen.                                                                                   |
| <b>bel</b>   | Produces an audible signal (such as a bell or a beep).                                                                                                                                                                                                                                         |
| <b>bw</b>    | Indicates that a backspace from the left edge of the terminal moves the cursor to the last column of the previous row.                                                                                                                                                                         |
| <b>clear</b> | Clears the screen, leaving the cursor in the home position.                                                                                                                                                                                                                                    |
| <b>cols</b>  | Specifies the number of columns on each line for the terminal.                                                                                                                                                                                                                                 |
| <b>cr</b>    | Moves the cursor to the left edge of the current row. This code is usually carriage return (Ctrl-M).                                                                                                                                                                                           |
| <b>cub1</b>  | Moves the cursor one space to the left, such as backspace.                                                                                                                                                                                                                                     |
| <b>cuf1</b>  | Moves the cursor to the right one space.                                                                                                                                                                                                                                                       |
| <b>cuu1</b>  | Moves the cursor up one space.                                                                                                                                                                                                                                                                 |
| <b>cud1</b>  | Move the cursor down one space.                                                                                                                                                                                                                                                                |
| <b>hc</b>    | Specifies a printing terminal with no softcopy unit. You should also specify the <b>os</b> capability.                                                                                                                                                                                         |
| <b>ind</b>   | Scrolls text up.                                                                                                                                                                                                                                                                               |
| <b>lf</b>    | Specifies a line-feed.                                                                                                                                                                                                                                                                         |
| <b>lines</b> | Specifies the number of lines on a cathode ray tube (CRT) terminal.                                                                                                                                                                                                                            |
| <b>nel</b>   | Specifies a newline. The terminal behaves as if it received a carriage return followed by a line feed.                                                                                                                                                                                         |
| <b>os</b>    | Indicates that when a character is displayed or printed in a position already occupied by another character, the terminal overstrikes the existing character, rather than replacing it with the new character. The <b>os</b> capability applies to storage scope, printing, and APL terminals. |

| Item | Description        |
|------|--------------------|
| ri   | Scrolls text down. |

If the LINES and COLUMNS environment variables are set, these variables override the values in the **terminfo** database.

The local cursor motions encoded in the **terminfo** database files are undefined at the left and top edges of a CRT terminal. Programs should never attempt to backspace around the left edge (unless the **bw** string is given) or to go up locally off the top.

To scroll text up, a program should go to the bottom left corner of the screen and send the index string. To scroll text down, a program goes to the top left corner of the screen and sends the reverse index string. The index string is specified by the **ind** capability and the reverse index string is specified by the **ri** capability. The index string and the reverse index string are undefined when not on their respective corners of the screen.

The **am** capability determines whether the cursor sticks at the right edge of the screen when text is output, but this does not necessarily apply when the cursor is moved to the right (the **cuf1** capability) from the last column. A terminal has local motion from the left edge only if the **bw** capability is defined. The cursor then goes to the right edge of the previous row when moved to the left (the **cub1** capability) from the left edge. If the terminal does not have the **bw** capability, the effect is undefined, which is useful for drawing a box around the edge of the screen, for example.

A terminal has switch-selectable automatic margins if the **am** capability is specified. If the terminal has a command that moves to the first column of the next line, you can define the **nel** (new-line) capability. It does not matter whether the command clears the remainder of the current line. Therefore, if the terminal has no **cr** and **If**, a working **nel** can still be crafted out of one or both of them.

These capabilities suffice to describe printing terminals and simple CRT terminals. Thus, the Model 33 Teletype is described as:

```
33 | tty33 | tty | Model 33 Teletype
 bel=^G, cols#72, cr=^M, cud1=^J, hc, ind=^J, os, xon,
```

Another terminal is described as:

```
xxxx | x | xxxxxxxx,
 am, bel=^G, clear=^Z, cols#80, cr=^M, cub1=^H, cud1=^J,
 ind=^J, lines#24,
```

## Parameterized Strings

Cursor-addressing and other strings requiring parameters are described by parameterized string capabilities. These strings have escape sequences similar to the **printf %x** format. For example, to address the cursor, you specify the **cup** capability using the row and column parameters.

The parameterized capabilities include:

| Item        | Description                                                                                                                                                                  |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cub1</b> | Backspaces the cursor one space.                                                                                                                                             |
| <b>cup</b>  | Addresses the cursor using the row and column parameters. Rows and columns are numbered starting with 0 and refer to the physical screen visible to the user, not to memory. |

| Item                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>hpa</b> and <b>vpa</b>  | Indicates the cursor has row or column absolute cursor addressing; horizontal position absolute ( <b>hpa</b> ) or vertical absolute ( <b>vpa</b> ).                                                                                                                                                                                                                                                                                                                                                            |
|                            | Sometimes the <b>hpa</b> and <b>vpa</b> capabilities are shorter than the more general two-parameter sequence and you can use them in preference to the <b>cup</b> capability. Parameterized local motions (such as, a move of <i>n</i> spaces to the right) are defined with the <b>cud</b> , <b>cub</b> , <b>cuf</b> , and <b>cuu</b> capabilities, with a single parameter indicating how many spaces to move. These capabilities are primarily useful if the terminal does not have <b>cup</b> capability. |
| <b>indn</b> and <b>rin</b> | Scrolls text. These are parameterized versions of the basic <b>ind</b> and <b>ri</b> capabilities. The <i>n</i> value is a number of lines.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>mrcup</b>               | Indicates the terminal has memory-relative cursor addressing.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

The parameter mechanism uses a stack and has special % (percent sign) codes to manipulate the stack. Typically, a sequence pushes one of the parameters onto the stack and then prints it in some format. Often, more complex operations are necessary. The encodings have the following meanings:

| Item                                              | Description                                                                                                                                                                                                        |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>%%</b>                                         | Outputs a % (percent sign).                                                                                                                                                                                        |
| <b>%[ [:] Flags] [Width [.Precision] ] [doxs]</b> | As in the <b>printf</b> command, flags are the [- + # ] and space.                                                                                                                                                 |
| <b>%d</b>                                         | Prints pop() as in the <b>printf</b> command (numeric string from stack).                                                                                                                                          |
| <b>%2d</b>                                        | Prints pop() like <b>%2d</b> (minimum 2 digits output from stack).                                                                                                                                                 |
| <b>%3d</b>                                        | Prints pop() like <b>%3d</b> (minimum 3 digits output from stack).                                                                                                                                                 |
| <b>%02d</b>                                       | Prints as in the <b>printf</b> command (2 digits output).                                                                                                                                                          |
| <b>%03d</b>                                       | Prints as in the <b>printf</b> command (3 digits output).                                                                                                                                                          |
| <b>%c</b>                                         | Prints pop() gives <b>%c</b> (character output from stack).                                                                                                                                                        |
| <b>%s</b>                                         | Prints pop() gives <b>%s</b> (string output from stack).                                                                                                                                                           |
| <b>%p[i]</b>                                      | Pushes the <i>i</i> th parameter onto the stack where <i>i</i> is a number between 1 and 9.                                                                                                                        |
| <b>%P[a-z]</b>                                    | Sets variable [a-z] to pop() (variable output from stack).                                                                                                                                                         |
| <b>%g[a-z]</b>                                    | Gets variable [a-z] and pushes it onto the stack.                                                                                                                                                                  |
| <b>%'c'</b>                                       | Character constant <i>c</i> .                                                                                                                                                                                      |
| <b>%{nn}</b>                                      | Integer constant <i>nn</i> .                                                                                                                                                                                       |
| <b>%l</b>                                         | Push strlen (pop( ))                                                                                                                                                                                               |
| <b>%+ %- %* %/ %m</b>                             | Arithmetic operators (%m is modulus): push (pop() operation pop()).                                                                                                                                                |
| <b>%&amp; %  %^</b>                               | Bit operations: push (pop() operation pop()).                                                                                                                                                                      |
| <b>%= %&gt; %&lt;</b>                             | Logical operations: push (pop() operation pop()).                                                                                                                                                                  |
| <b>%! %~</b>                                      | Unary operations: push (operation pop()).                                                                                                                                                                          |
| <b>%i</b>                                         | Add 1 to first two parameters (for ANSI terminals).                                                                                                                                                                |
| <b>%?expr %t thenpart %e elsepart %;</b>          | If-then-else. The %e elsepart is optional. You can make an else-if construct as with Algol 68 in the following example, where ci denotes conditions and bi bodies.<br>%? ci %t bi %e c2 %t b2 %e c3 %t b3 %e b4 %; |

Binary operations are in postfix form with the operands in the usual order. That is, to get x - 5 use **%gx%{5}%-**.

If you use the - (minus sign) flag with **%[doxs]**, then you must place a colon between the % (percent sign) and the - (minus sign) to differentiate the flag from the %- binary operation, for example, **%:-16.16s**.

Consider a terminal that needs to be sent \E&a12c03Y padded for 6 milliseconds to get to row 3 and column 12. Here the order of the rows and columns is inverted, and the row and column are zero-padded as two digits. Thus, the **cup** capability of this terminal is **cup=\E&a%p2%2.2dc%p1%2.2dY\$<6>**.

Some terminals need the current row and column sent, preceded by a **^T**, with the row and column encoded in binary: **cup=^T%p1%c%p2%c**. Terminals that use **%c** need to be able to backspace the cursor

(**cub1**) and to move the cursor up one line on the screen (**cuu1**). This is necessary because it is not always safe to transmit **\n**, **^D**, and **\r** characters, since the system may change or discard them.

**Note:** The library routines dealing with the **terminfo** database files set terminal modes so that tabs are not expanded by the operating system; thus, **\t** (tab) is safe to send.

A final example is a terminal that uses row and column offset by a blank character: **cup=\E=%p1%\s'%'%c %p2'\s'%'%c**. After sending **\E=**, this operation pushes the first parameter, pushes the ASCII value for a space (32), adds them (pushing the sum on the stack in place of the two previous values), and outputs that value as a character. Then the same is done for the second parameter. More complex arithmetic is possible using the stack.

## Cursor Motions

The top left corner of the screen is the home position. If the terminal has a fast way to get the cursor to the home position, specify the **home** capability. Specify a fast way of getting to the bottom left corner with the **ll** capability. This method may involve going up (**cuu1**) from the home position, but a program should never do this itself (unless **ll** does) because the effect of moving up from the home position is not certain.

**Note:** The home position is the same as addressing (0,0) to the top left corner of the screen, not of memory.

If the terminal has row or column absolute-cursor addressing, you should specify the single **hpa** capability (horizontal position above) and the **vpa** capability (vertical position absolute). Sometimes these are shorter than the more general two parameter sequence and you can use them instead of the **cup** capability.

If the terminal has parameterized local motions for example, it is capable of moving the cursor *n* spaces right, you can specify the **cud**, **cub**, **cuf**, and **cuu** capabilities with a single parameter indicating how many spaces to move. These capabilities are useful if the terminal does not have the **cup** capability.

## Area Clears

The following capabilities clear large areas of the terminal:

| Item       | Description                                                                                                                                                                                                                         |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ed</b>  | Clears from the current position to the end of the display. This is defined only from the first column of a line. (Thus, it can be simulated by a request to delete a large number of lines, if a true <b>ed</b> is not available.) |
| <b>el</b>  | Clears from the current cursor position to the end of the line without moving the cursor.                                                                                                                                           |
| <b>el1</b> | Clears from the beginning of the line to the current position, inclusive. The cursor is not moved.                                                                                                                                  |

## Scrolling

The following insert-line and delete-line capabilities are used to indicate a terminal can:

| Item       | Description                                                                                                                                                                                                                                                                        |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>csr</b> | Change the scrolling region. This capability takes two parameters: the top and bottom lines of the scrolling region. The top line of the screen is 0. After using this capability, the cursor position is undefined. See the <b>sc</b> and <b>rc</b> capabilities in this section. |
| <b>da</b>  | Retain the display above the screen. If a line is deleted or the screen is scrolled, non-blank lines can be brought in at the top. This capability is usually defined for multipage terminals.                                                                                     |
| <b>db</b>  | Retain the display below the screen. If a line is deleted or the screen is reverse scrolled, the terminal can bring the non-blank lines at the bottom. This capability is usually defined for multipage terminals.                                                                 |
| <b>dl1</b> | Delete the line the cursor is on. This is done only from the first position on the line to be deleted. Additionally, the <b>dl</b> capability takes a single parameter indicating the number of lines to be deleted.                                                               |

| Item        | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>il1</b>  | Create a new blank line before the line where the cursor is currently located and scrolls the rest of the screen down. This is done only from the first position of a line. The cursor then appears on the newly blank line. Additionally, the <b>il</b> capability can take a single parameter indicating the number of lines to insert.                           |
| <b>ind</b>  | Index or scroll forward. A terminal with this capability can shift the display up one line by deleting the top line and adding a blank line at the bottom.                                                                                                                                                                                                          |
| <b>indn</b> | Specify the number of lines to scroll forward. This capability has meaning only if the <b>ind</b> capability is also defined.                                                                                                                                                                                                                                       |
| <b>rc</b>   | Restore the cursor. This capability is useful with the <b>csr</b> and <b>sc</b> capabilities.                                                                                                                                                                                                                                                                       |
| <b>ri</b>   | Reverse scrolling. With this capability, the terminal can shift the screen down by deleting the bottom line and adding a blank line at the top.                                                                                                                                                                                                                     |
| <b>rin</b>  | Specify the number of lines to reverse scroll. This capability has meaning only if the <b>ri</b> capability also is defined.                                                                                                                                                                                                                                        |
| <b>sc</b>   | Save the cursor. If defined, you can use the <b>sc</b> capability to save the cursor before using the <b>csr</b> capability. Saving the cursor is necessary because the cursor position is undefined after you use the <b>csr</b> capability. Use the <b>rc</b> capability to restore the cursor to the position it held before you used the <b>csr</b> capability. |
| <b>wind</b> | Indicates the terminal has the ability to define a window as part of memory. This is a parameterized string capability with four parameters: the starting and ending lines in memory and the starting and ending columns in memory, in that order.                                                                                                                  |

A terminal that has the **csr** capability can scroll part of its screen while leaving other lines above and below the region untouched. A forward scroll applied to a region deletes the top of the region, shifts, and adds a line to the bottom of the region. When finished with the scrolling region, you should use the **csr** capability to restore the scrolling region to the full screen.

Be sure you move the cursor into the scrolling region with the **cup** capability before you attempt to scroll the region. You should not move the cursor from the region until you are done with it.

**Note:** If you are using a terminals **csr** capability, you may also need to use the **sc** and **rc** capability.

Terminals that have **csr** defined have a destructive scrolling region. Once a line is scrolled off the screen, the terminal cannot retrieve it. A terminal with a non-destructive scrolling region can restore scrolled lines by reversing the scrolling. Unless the **ind**, **ri**, **indn**, **rin**, **dl**, and **dl1** all simulate destructive scrolling, do not specify the **csr** capability if the terminal has non-destructive scrolling regions.

On multipage terminals, scrolling can put a line onto another page and scrolling in the opposite direction brings the line back. Similarly, deleting a line can cause a line from another page to appear on the screen. Multipage terminals should have the **da** and **db** capabilities defined so that program that use scrolling can adjust their behavior.

A few terminals can define a window as part of memory. For these types of terminals, all clearing, deletion, insertion, and wrapping commands affect the area in memory where the window is defined.

## Insert or Delete Character

Generally, terminals handle insert/delete character operations in one of two ways. The most common insert/delete character operations affect only the characters on the current line and shift characters to the right and off the line. Other terminals make a distinctions between typed and untyped blanks on the screen. When inserting a character, the displayed data is shifted and an untyped blank is eliminated. Once all the untyped blanks are eliminated, the displayed data wraps to the next line if you continue to insert characters. When deleting a character, an untyped blank is added to the line to compensate for the deleted character.

Generally, terminals insert/delete characters in one-line mode or multiline mode. The two types of terminals also handle untyped spaces differently. One-line mode is the most common mode. In one-line mode, insert/delete character operations affect only the characters on the current line. Insertions shift characters to the right and off the line.

Multiline mode terminals can affect more than one line. In this mode, the terminal makes a distinction between typed and untyped blanks on the screen. Inserting a character on a multiline mode terminal shifts the displayed data and eliminates untyped blanks. If all the untyped blanks are eliminated and you continue to insert characters, the display wraps to the next line. When deleting a character, multiline terminals add an untyped blank to the line to compensate for the deleted character.

## Determining Your Terminal's Type

Clearing a screen and then typing text separated by cursor motions helps you determine the type of insert/delete operations your terminal performs. Clear the screen, then proceed as follows:

1. Type abc def using local cursor movements, not spaces, between the abc and the def.
2. Position the cursor before the abc.
3. Place the terminal in insert mode.
4. Type a line of text. If your typing causes the abc def characters to shift right and exit the right side of the display, the terminal does not distinguish between blanks and untyped positions.

If the abc moves to positions to the immediate left of the def and the characters move to the right on the line, around the end, and to the next line, the terminal is the second type. This is described by the **in** capability, which signifies insert null.

Although these two attributes (one-line versus multiline insert mode, and different treatment of untyped spaces) are logically separate, there are no known terminals whose insert mode cannot be described with a single attribute.

## Insert or Delete Character Capabilities

The **terminfo** database describes terminals that have an insert mode as well as terminals that send a simple sequence to open a blank position on the current line. The following are used to describe insert/delete character capabilities:

| Item        | Description                                                                                                                                                                                                                             |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dch1</b> | Deletes a single character. The <b>dch</b> capability with one parameter, <i>n</i> , deletes <i>n</i> characters.                                                                                                                       |
| <b>ech</b>  | Replaces the specified number of characters, starting at the cursor, with blanks. The cursor position remains unchanged.                                                                                                                |
| <b>ich1</b> | Opens a space in a line for a character to be inserted. This sequence precedes the actual character insertion. Terminals with a true insert mode would not use this capability.                                                         |
| <b>ip</b>   | Indicates post-padding needed. This is given as a number of milliseconds. Any other sequence that may need to be sent after inserting a single character can be given in this capability.                                               |
| <b>mir</b>  | Allows cursor movement while in insert mode. It is sometimes necessary to move the cursor while in insert mode to delete characters on the same line. Some terminals may not have this capability due to their handling of insert mode. |
| <b>rmdc</b> | Exits delete mode.                                                                                                                                                                                                                      |
| <b>rmir</b> | Ends insert mode.                                                                                                                                                                                                                       |
| <b>rmp</b>  | Indicates that padding is necessary between characters typed while not in insert mode. This capability is used in replace mode.                                                                                                         |
| <b>smdc</b> | Enters delete mode.                                                                                                                                                                                                                     |
| <b>smir</b> | Begins insert mode.                                                                                                                                                                                                                     |

If you are creating a **terminfo** description for a terminal that requires an insert mode and also needs a special code to precede each inserted character, then define the **smir/rmr**, and **ich1** capabilities. The **ich** capability, with the one parameter *n*, opens up *n* spaces so that *n* characters can be inserted.

## Highlighting, Underlining, and Visual Bells

If your terminal has one or more kinds of display attributes, such as highlighting, underlining, and visual bells, you can present these in a number of ways. Highlighting, such as standout mode, presents a high-contrast, easy-to-read format that adds emphasis to error messages and other important messages.

Underlining is another method to focus attention on a particular portion of the terminal. Visual bells include methods such as flashing the screen. The following capabilities describe highlighting, underlining, and visual bells:

- blink** Indicates terminal has blink highlighting mode.
  - bold** Indicates terminal has extra bright highlighting mode.
  - civis** Makes the cursor invisible.
  - cnorm** Displays a normal cursor. This capability reverses the effects of the **civis** and **cvvis** capabilities.
  - cvvis** Makes the cursor more visible than normal when it is not on the bottom line.
  - dim** Indicates the terminal has half-bright highlighting modes.
  - eo** Indicates that blanks erase overstrikes.
  - enacs** Specifies a command string that enables alternate character set mode. Some terminals cannot enter alternate character set mode without first receiving a specific command. The **enacs** capability defines the command.
  - flash** Indicates the terminal has a way of making the screen flash (as a bell replacement) for errors, without moving the cursor.
  - invis** Indicates the terminal has blanking or invisible-text highlighting modes.
  - msgr** Indicates it is safe to move the cursor in standout mode. Otherwise, programs using standout mode should exit this mode before moving the cursor or sending a new-line. Some terminals automatically leave standout mode when they move to a new line or when the cursor is addressed.
  - nrrmc** Indicates that the **smcup** sequence does not restore the screen after a **rmcup** sequence is output. This means that you cannot restore the screen to the state prior to outputting **rmcup**.
  - os** Indicates the terminal can overstrike an existing character without erasing the original. Overstriking creates a compound character.
  - prot** Indicates the terminal has protected text mode. This means the terminal protects the text from overwriting or erasing. The method of protection is terminal dependent.
  - rev** Indicates the terminal has reverse-video mode.
  - rmacs** Exits the alternate character set mode.
  - rmso** Exits standout mode.
  - rmul** Ends underlining.
  - sgr** Provides a sequence to set arbitrary combinations of attributes. The **sgr** capability can set nine attributes. In order, these attributes are the following:
    - standout
    - underline
    - blink
    - dim
    - bold
    - blank
    - protect
    - alternate character set
- To turn a mode on, set it to a nonzero value. To turn a mode off, set it to 0. The **sgr** capability can only support those modes for which separate capabilities already exist on the terminal.
- sgr0** Turns off all the special modes, including the alternate character set.

**smacs** Enters the alternate character set mode.

#### **smcup and rmcup**

Indicate the terminal must be in a special mode when running a program that uses any of the highlighting, underlining, or visual bell capabilities. The **smcup** capability enters this mode, and the **rmcup** capability exits this mode.

This need arises, for example, with terminals having more than one page of memory. If the terminal has only memory-relative cursor addressing, and not screen-relative cursor addressing, a screen-sized window must be fixed into the terminal for cursor addressing to work properly. This is also used when the **smcup** capability sets the command character to be used by the **terminfo** database file.

**sms0** Enters standout mode.

**smul** Begins underlining.

**uc** Underlines the current character and moves the cursor one space to the right.

**ul** Indicates the terminal correctly generates underlined characters (with no special codes needed), even though it does not overstrike.

**xmc** Indicates the number of blanks left if the capability to enter or exit standout mode leaves blank spaces on the screen.

#### **Highlighting, Overstriking, and Underlining**

You should choose one display method as standout mode and use it to highlight error messages and other kinds of text to which you want to draw attention. For example, you could choose reverse-video plus half-bright or reverse-video alone. The sequences to enter and exit standout mode are given by the **sms0** and **rmos0** capabilities. If the code to change into or out of standout mode leaves one or even two blank spaces on the screen, then **xmc** should be given to tell how many spaces are left.

You should specify the **ul** boolean capability if your terminal generates underlined characters by using the underline character with no special codes. You should specify this capability even if the terminal does not otherwise overstrike characters. For terminals where a character overstriking another leaves both characters on the screen, specify the **os** capability. If the terminal can erase overstrikes with a blank, then indicate this by specifying the **eo** capability.

#### **Example of Using the sgr Capability**

The following example demonstrates how to use the **sgr** capability to turn on various modes. Assume that you must define a terminal that requires the following escape sequences to turn on various modes:

| Terminfo Parameter | Mode       | Escape Sequence  |
|--------------------|------------|------------------|
|                    | none       | \E[0m            |
| p1                 | standout   | \E[0;4;7m        |
| p2                 | underline  | \E[0;3m          |
| p3                 | reverse    | \E[0;4m          |
| p4                 | blink      | \E[0;5m          |
| p5                 | dim        | \E[0;7m          |
| p6                 | bold       | \E[0;3;4m        |
| p7                 | invis      | \E[0;8m          |
| p8                 | protect    | not available    |
| p9                 | altcharset | ^0 (off) ^N (on) |

**Note:** Each escape sequence requires a 0 to turn off other modes before turning on its own mode.

You can simulate some modes by combining others. In this example, the **standout** attribute escape sequence is a combination of the **reverse** and **dim** sequences. Also, in the example the **bold** sequence is a combination of the **reverse** and **underline** sequences. To combine such modes as **underline** and **blink**, the sequence to use would be `\E[0;3;5m`.

You cannot simulate certain modes by combining others. For example, you cannot simulate the **protect** mode. In this example, the system ignores the p8 parameter. The **altcharset** mode is different in that it is either `^O` or `^N`, depending on whether the alternate character mode set is on or off. If all modes were turned on, the sequence would appear as `\E[0;3;4;5;7;8m^N`.

Some sequences are outputted for one or more modes. For example, the ;3 is outputted when either the p2 parameter or p6 parameter is true. If you write out the above sequences along with their dependencies, the result is the following;

| Sequence              | When To Output    | terminfo Translation               |
|-----------------------|-------------------|------------------------------------|
| <code>\E[0</code>     | always            | <code>\E[0</code>                  |
| <code>;3</code>       | if p2 or p6       | <code>%?%p2%p6% %t;3%;</code>      |
| <code>;4</code>       | if p1 or p3 or p6 | <code>%?%p1%p3% %p6% %t;4%;</code> |
| <code>;5</code>       | if p4             | <code>%?%p4%t;5%;</code>           |
| <code>;7</code>       | if p1 or p5       | <code>%?%p1%p5% %t;7%;</code>      |
| <code>;8</code>       | if p7             | <code>%?%p1%t;8%;</code>           |
| <code>m</code>        | always            | <code>m</code>                     |
| <code>^N or ^O</code> | if p9 ^N, else ^O | <code>%?%p9%t^N%e^0%;</code>       |

The final result would produce a **sgr** sequence that appears as follows:

```
sgr=\E[0;%?%p2%p6%|%t;3;%?%p1%p3%|%p6%|%t;4%;%?%p4%t;5;%?%p1%p5%|
%t;7%;%?%p1%t;8%;m%?%p9%t^N%e^0%;,
```

## Keypad

If the terminal has a keypad that transmits codes when the keys are pressed, you can define this in the **terminfo** entry for the terminal. It is not possible to handle terminals where the keypad only works in local mode. If the keypad can be set to transmit or not transmit, give these codes as **smkx** and **rmkx**. Otherwise, the keypad is assumed to always transmit.

To define the codes sent by the left-arrow, right-arrow, up-arrow, down-arrow, and home keys, use the **kcub1**, **kcuf1**, **kcud1**, and **khome** capabilities, respectively. If there are function keys such as F0, F1, ..., F63, the codes they send can be given as the **kf0**, **kf1**, ..., **kf63** capabilities. If the first eleven keys have labels other than the default F0 through F10, you can specify the labels with the **lf0**, **lf1**, ..., **lf10** capabilities. The codes transmitted by certain other special keys can be defined with:

| Item         | Description                                                                     |
|--------------|---------------------------------------------------------------------------------|
| <b>kbs</b>   | Backspace key.                                                                  |
| <b>kclr</b>  | Clear-screen or erase key.                                                      |
| <b>kctab</b> | Clear the tab stop in this column.                                              |
| <b>kdch1</b> | Delete-character key.                                                           |
| <b>kdl1</b>  | Delete-line key.                                                                |
| <b>ked</b>   | Clear to end of screen.                                                         |
| <b>kel</b>   | Clear to end of line.                                                           |
| <b>khts</b>  | Set a tab stop in this column.                                                  |
| <b>kich1</b> | Insert character or enter insert mode.                                          |
| <b>kil1</b>  | Insert line.                                                                    |
| <b>kind</b>  | Scroll forward or down, or both.                                                |
| <b>kll</b>   | Home down key (home is the lower left corner of the display, in this instance). |
| <b>krmir</b> | Exit insert mode.                                                               |
| <b>knp</b>   | Next page.                                                                      |
| <b>kpp</b>   | Previous page.                                                                  |

| Item        | Description                     |
|-------------|---------------------------------|
| <b>ktbc</b> | Clear-all-tabs key.             |
| <b>ri</b>   | Scroll backward or up, or both. |

In addition, if the keypad has a three-by-three array of keys including the four arrow keys, specify the other five keys as **ka1**, **ka3**, **kb2**, **kc1**, and **kc3**. These keys are useful when you need the effects of a three-by-three directional pad.

Strings that program function keys can be given as the **pfkey**, **pfloc**, and **pfx** capabilities. A string to program the soft screen labels can be given as **pln**. Each of these strings takes two parameters: the function key number to program (from 0 to 10) and the string with which to program it. Function key numbers out of this range can program undefined keys in a terminal-dependent manner. The capabilities differ in that **pfkey** causes pressing a given key to be the same as the user typing the given string, **pfloc** causes the string to be executed by the terminal in local mode, and **pfx** causes the string to be transmitted to the computer. The capabilities **nlab**, **lw**, and **lh** define the number of soft labels and the width and height. Use **smln** and **rmln** to specify the commands for turning on and off soft labels. **smln** is normally output after one or more **pln** sequences to ensure the change becomes visible.

## Tabs and Initialization

If the terminal has hardware tabs, you can use **ht** capability (usually Ctrl-I) to specify the command to advance to the next tab stop. To specify the command to move left toward the previous tab stop, use the **cbt** capability. By convention, if the terminal modes indicate that operating system is expanding the tabs rather than sending them to the terminal, programs should not use the **ht** or **cbt** capabilities even if they are present, since the user may not have the tab stops properly set.

If the terminal has hardware tabs that are initially set every *n* spaces when the terminal is powered up, its **terminfo** description should define the numeric capability **it** to show the number of spaces the tabs are set to. Normally, the **tput init** command uses the **it** parameter to determine whether to set the mode for hardware tab expansion and whether to set the tab stops. If the terminal has tab stops that can be saved in nonvolatile memory, the **terminfo** description can assume that they are properly set.

Other, similar capabilities include the **is1**, **is2**, and **is3** initialization strings for the terminal; the **iprog** capability that specifies the terminal's initialization program, and the **if** capability that identifies the name of a file containing long initialization strings. These strings are expected to set the terminal into modes consistent with the rest of the **terminfo** file description. They are normally sent to the terminal by the **tput init** command each time the user logs in. When the user logs in, the system does the following:

- Runs the **iprog** program.
- Prints **is1**.
- Print **is2**.
- Sets the margins using the **mgc**, **smgl**, and **smgr** capabilities.
- Sets the tabs using **tbc** and **hts** capabilities.
- Prints the **if** file.
- Prints **is3**.

You can set up special terminal modes without duplicating strings by putting the common sequences in the **is2** capability and special cases in the **is1** and **is3** capabilities. To specify sequences that do a harder reset from a totally unknown state, specify the **rs1**, **rs2**, **rs3**, and **rf** capabilities that are the same as **is1**, **is2**, **is3**, and the **if** capabilities.

A few terminals use the **if** and **rf** files. However, the recommended method is to use the initialization and reset strings. These strings are output by the **tput reset** command. This command is used when the terminal starts behaving strangely or is not responding at all. Commands are normally placed in the **rs1**,

**rs2**, **rs3** and **rf** capabilities only if they produce annoying effects on the screen and are not necessary when logging in. For example, the command to set the terminal into 80-column mode would normally be part of **is2**, but it causes an annoying screen behavior and is not necessary since most terminals initialize in 80-column mode.

If there are commands to set and clear tab stops, specify them using the **tbc** (clear all tab stops) and the **hts** (set a tab stop in the current column of every row) capabilities. If a more complex sequence is needed to set the tabs, the place the sequence in the **is2** or the **if** capability.

The **mgc** capability can clear any margin. For more information about how to set and clear margins, see Margins.

## Miscellaneous Strings

If the terminal requires a character other than a null character as a pad, then specify the **pad** string. Only the first character of the **pad** string is used. If a terminal does not have a pad character, specify the **npc** capability.

If the terminal can move up or down half a line, define the **hu** (half-line up) and **hd** (half-line down) capabilities. These capabilities are primarily useful for superscripts and subscripts on hardcopy terminals. If a hardcopy terminal can eject to the next page (form feed), specify the as **ff** (usually Ctrl-L) capability.

If there is a command to repeat a given character a given number of times (to save time transmitting a large number of identical characters), this can be indicated with the **rep** parameterized string. The first parameter is the character to be repeated, and the second is the number of times to repeat it. Thus following:

```
tparm(repeat_char,'x',10)
```

is the same as

```
xxxxxxxxxx
```

If the terminal has a settable command character, such as the Tektronix 4025, indicate this with the **cmdch** capability. A prototype command character is chosen that is used in all capabilities. This character is given in the **cmdch** capability to identify it. On some UNIX systems, if the **CC** environment variable exists, all occurrences of the prototype character are replaced with the character in the **CC** variable.

Terminal descriptions that do not represent a specific kind of known terminal such as switch, dialup, patch, and network, should include the **gn** (generic) capability. This capability allows programs to return errors if they cannot talk to the terminal. The **gn** capability does not apply to virtual terminal descriptions for which the escape sequences are known. If a terminal is supported by the UNIX system virtual terminal protocol, use the **vt** capability to define its terminal number.

If a terminal uses xon/xoff handshaking for the flow control, its description should include the **xon** capability. You should still include padding information as well so that routines can make better decisions about costs. However, actual pad characters are not transmitted. To specify sequences to turn on and off xon/xoff handshaking, use the **smxon** and **rmxon** capabilities. If the characters used for handshaking are not ^S and ^Q, use the **xonc** and **xoffc** capabilities to define them.

If a terminal has a meta key that acts as a shift key to set the eighth bit of any character transmitted, identify the key with the **km** capability. Otherwise, software assumes that the eighth bit is parity, and it will usually be cleared. If strings exist to turn this meta mode on and off, they can be given as the **smm** and **rmm** capabilities.

If a terminal has more lines of memory than fit on the screen at once, use the **lm** capability to define the number of lines of memory. A value of **lm#0** indicates that the number of lines is not fixed, but that there are still more lines of memory than fit on the screen.

Media copy strings that control an auxiliary printer connected to the terminal are identified with the following capabilities:

| Item | Description                                                                                                                                                                                           |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| mc0  | Prints the contents of the screen                                                                                                                                                                     |
| mc4  | Turns off the printer, and                                                                                                                                                                            |
| mc5  | Turns on the printer. When the printer is on, all text sent to the terminal is sent to the printer. It is undefined whether the text is also displayed on the terminal screen when the printer is on. |
| mc5p | Leaves the printer on for a specified number of characters and then turns the printer off. The parameter passed to mc5p should not exceed 255.                                                        |

If the terminal screen does not display the text when the printer is on, specify the **mc5i** capability to signify a silent printer. All text, including the **mc4**, is transparently passed to the printer while an **mc5p** is in effect.

## Status Lines

You can use the **terminfo** entry to indicate that the terminal has an extra status line that is not normally used by software,. If the status line is viewed as an extra line below the bottom line, into which the cursor can be addressed normally, the **hs** capability should be given. Special strings to go to the beginning of the status line and to return from the status line can be given as the **tsl** and **fsl** capabilities, respectively. (The **fsl** must leave the cursor position in the same place it was before the **tsl**. If necessary, the **sc** string and the **rc** string can be included in **tsl** and **fsl** to get this effect.) The **tsl** capability takes one parameter, which is the column number of the status line to which the cursor is to be moved.

If escape sequences and other special commands, such as tab, work while in the status line, specify the **eslok** capability. A string that turns off the status line (or otherwise erases its contents) should be given as **dsl**. If the terminal has commands to save and restore the position of the cursor, give them as **sc** and **rc** capabilities. The status line is normally assumed to be the same width as the rest of the screen, such as **cols**. If the status line is a different width (possibly because the terminal does not allow an entire line to be loaded), the width, in columns, can be indicated with the **wsl** numeric parameter.

## Line Graphics

If the terminal has a line drawing alternate character set, specify the mapping of glyph to character in the **acsc** capability. The definition of this string is based on the alternate character set used in the DEC VT100 terminal, extended slightly with some characters from the AT&T4410v1 terminal. Use the following to define the string:

| Glyph Name            | vt100+ Character |
|-----------------------|------------------|
| arrow pointing right  | +                |
| arrow pointing left   | ,                |
| arrow pointing down   | .                |
| solid square block    | 0                |
| lantern symbol        | I                |
| arrow pointing up     | -                |
| diamond               | '                |
| check board (stipple) | a                |
| degree symbol         | f                |
| plus or minus sign    | g                |
| board of squares      | h                |
| lower right corner    | j                |
| upper right corner    | k                |
| upper left corner     | l                |
| lower left corner     | m                |
| plus                  | n                |
| scan line 1           | o                |

| Glyph Name      | vt100+ Character |
|-----------------|------------------|
| horizontal line | q                |
| scan line 9     | s                |
| left tee        | t                |
| right tee       | u                |
| bottom tee      | v                |
| top tee         | w                |
| vertical line   | x                |
| bullet          | ~                |

The best way to describe a new terminal's line graphics set is to add a third column to the above table with the characters for the new terminal that would produce the appropriate glyph when the terminal is in alternate character set mode. For example:

| glyph name         | vt100<br>character | tty<br>character |
|--------------------|--------------------|------------------|
| upper left corner  | l                  | R                |
| lower left corner  | m                  | F                |
| upper right corner | k                  | T                |
| lower right corner | j                  | G                |
| horizontal line    | q                  | ,                |
| vertical line      | x                  | .                |

Then, you specify the **acsc** capability by specifying the characters from left to right as follows:  
**acsc=lrMfkTjGq\,x.**

## Color Manipulation

There are two methods of color manipulation, the HP method and the Tektronix method. Most existing color terminals belong to one of these two classes. The Tektronix method uses a set of  $N$  predefined colors (usually 8) from which a user can select *current* foreground and background colors. Thus, the terminal can support up to  $N$  colors mixed into  $N^2$  color-pairs that are displayed on the screen at the same time.

The HP method restricts the user from both defining the foreground independently of the background or the background independently of the foreground. Instead, the user must define an entire color-pair at once. Up to  $M$  color-pairs, made from  $2^*M$  different colors, can be defined this way.

The numeric variables **colors** and **pairs** define the number of colors and color-pairs that the terminal can display on the screen at one time. If a terminal can change the definition of a color, you should specify the **ccc** capability. To change the definition of a color using the Tektronix method, use the **initc** capability. This capability requires four parameters: a color number ranging from 0 to colors-1 and three Red, Green, Blue (RGB) values ranging from 0 to 1,000.

Tektronix 4100 series terminals use a type of color notation called HLS (Hue Lightness Saturation) instead of RGB color notation. For such terminals, you should define the **hls** boolean capability. The last three arguments to the **initc** capability would then be HLS values where H ranges from 0 to 360 and L and S range from 0 to 100.

**Note:** If a terminal can change the definitions of colors but uses a color notation different from RGB or HLS, you must develop a mapping to either RGB or HLS.

To set current foreground and background to a given color, use the **setf** and **setb** capabilities. These capabilities require a single parameter that specifies the number of the color. To use the HP method to initialize a color-pair, use the **initp** capability. This capability requires seven parameters:

- the number of the color-pair in the range of 0 to pairs -1
- three RGB values for the foreground
- three RGB values fro the background

When you use the **initc** or **inittp** capabilities, be sure you specify the values in the order red, green, blue or hue, lightness, saturation, respectively. To make a color-pair current, use the **scp** capability. This capability takes one parameter, the number of the color-pair.

Some terminals erase areas of the screen with the current background color. In such cases, define the **bce** capability. The **op** capability contains a sequence for setting the foreground and the background colors to what they were at the terminal start-up time. Similarly, the **oc** capability contains a control sequence for setting all colors or -pairs to the values they had at the terminal start-up time.

Some color terminals substitute color for video attributes. Such video attributes should not be combined with colors. You should pack information about these video attributes into the **ncv** capability. There is a one-to-one correspondence between the nine least significant bits of that variable and the video attributes. The following table depicts this correspondence:

| Attribute    | NCV Bit Number |
|--------------|----------------|
| A_STANDOUT   | 0              |
| A_UNDERLINE  | 1              |
| A_REVERSE    | 2              |
| A_BLINK      | 3              |
| A_DIM        | 4              |
| A_BOLD       | 5              |
| A_INVIS      | 6              |
| A_PROTECT    | 7              |
| A_ALTCHARSET | 8              |

When a particular video attribute should not be used with colors, the corresponding **ncv** bit should be set to 1. Otherwise, set the bit to 0. For example, if the terminal uses colors to simulate reverse video and bold, bits 2 and 5 should be set to 1. The resulting values for **ncv** will be 22.

## Special Cases

Some terminals require special support by the **terminfo** database. These terminals are not deficient. These terminals have hardware that may be slightly different than what the **terminfo** database expects of most terminals. Some of the special cases are discussed in this section. The programmer's manual for a terminal should provided all the information you need to code a **terminfo** description for the terminal.

For terminals that do not allow the ~ (tilde) character, use the **hz** capability.

Descriptions of terminals that ignore a line-feed character immediately after an **am** wrap should include the **xenl** capability. Those terminals whose cursor remains on the right-most column until another character is received rather than wrapping immediately upon receiving the right-most character, should also use the **xenl** capability.

If **el** capability is required to get rid of standout (instead of merely writing normal text on top of it), then you should specify **xhp** capability.

Terminals for which tabs change all moved characters into blanks should indicate the **xt** capability (destructive tabs). This capability is interpreted to mean that it is not possible to position the cursor on top of the pads inserted for standout mode. Instead, it is necessary to erase standout mode using delete and insert line.

A terminal that is unable to correctly transmit the ESC (escape) or Ctrl-C characters should specify the **xsb** capability, indicating that the F1 key is used for ESC and the F2 key is used for Ctrl-C.

Other specific terminal problems can be corrected by adding more capabilities.

## Similar Terminals

If two terminals are very similar, you can define one as being just like the other with the **use** string capability. You can also use all of the definitions from an existing description and identify exceptions. The capabilities given before the **use** capability override those in the terminal type called by the **use** capability. To cancel a capability place **xx@** to the left of the **use** capability definition, where **xx** is the capability. For example, the entry:

```
term-n1 | Terminal smkx@, rmkx@, use=term
```

defines a terminal that does not have either the **smkx** or the **rmkx** capability, and hence does not turn on the function key labels when in visual mode. This is useful for different terminal modes or for different user preferences. You can specify more than one **use** capability.

## Printer Capabilities

The **terminfo** database allows you to define the capabilities of printers as well as terminals. To find out what capabilities are available for printers as well as for terminals, see the two lists under Terminal Capabilities that list the capabilities by variable and by capability name.

### Rounding Values

Because parameterized string capabilities work only with integer values, we recommend that **terminfo** designers create strings that expect rounded numeric values. Programmers should always round values to the nearest integer before using them with a parameterized string capability.

### Printer Resolution

A printer's resolution is the smallest spacing of characters it can achieve. In general, printers have independent resolution horizontally and vertically. To determine the vertical resolution of a printer, measure the smallest achievable distance between consecutive printing baselines. To determine the horizontal resolution, measure the smallest achievable distance between the left-most edges of consecutive printed, identical, characters.

The **terminfo** database assumes all printers are capable of printing with a uniform horizontal and vertical resolution. The **terminfo** database currently interacts with printers as if they print inside a uniform matrix. All characters are printed at fixed positions relative to each cell in the matrix. Furthermore, each cell has the same size given by the smallest horizontal and vertical step sizes dictated by the resolution.

Many printers are capable of proportional printing where the horizontal spacing depends on the size of the last character printed. The **terminfo** database does not make use of this capability, although it does provide enough capability definitions to allow an application to simulate proportional printing.

A printer must not only be able to print characters as close together as the horizontal and vertical resolutions suggest, but also of moving to a position that is an integral multiple of the smallest distance away from a previous position. Thus, printed characters can be spaced apart a distance that is an integral multiple of the smallest distance, up to the length of width of a single page.

Some printers can have different resolutions depending on different modes. In normal mode, the existing **terminfo** capabilities are assumed to work on columns and lines, just like a video terminal. For example, the old **lines** capability specifies the length of a page in lines, and the **cols** capability specifies the width of

a page in columns. In **micro** mode many **terminfo** capabilities work on increments of lines and columns. With some printers, the **micro** mode may exist concurrently with **normal** mode, so that all the capabilities work at the same time.

## Specifying Printer Resolution

You can specify a printer's printing resolution with several different capabilities. Each capability specifies distance in a different way. The following capabilities define print resolution:

| Capability | Defined as                  |
|------------|-----------------------------|
| orhi       | steps per inch horizontally |
| orvi       | steps per inch vertically   |
| orc        | steps per column            |
| orl        | steps per line              |

When printing in normal mode, each character printed causes the printer to move to the next column, except in special cases described later. The distance moved is the same as the per-column resolution. Some printers cause an automatic movement to the next line when a character is printed in the rightmost position. The vertical distance moved is the same as the per-line resolution. When printing in micro mode, these distances can be different, and may be zero for some printers. The following specify printer resolution automatic motion after printing:

| Capability | Defined as                               |
|------------|------------------------------------------|
| orc        | Steps moved horizontally in normal mode. |
| orl        | Steps moved vertically in normal mode.   |
| mcs        | Steps moved horizontally in micro mode.  |
| mls        | Steps moved vertically in micro mode.    |

Some printers can print wide characters. The distance moved when a wide character is printed in normal mode may be different from when a regular width character is printed. The distance moved when a wide character is printed in micro mode may also be different from when a regular character is printed in micro mode, but the differences are assumed to be related.

If the distance moved for a regular character is the same in normal mode or micro mode (**mcs=ocs**), then the distance moved for a wide character is also the same in both modes. This does not mean the normal character distance is necessarily the same as the wide character distance, just that the distances do not change with a change from normal to micro mode. Use the **widcs** capability to specify the printer resolution when the automatic motion after printing a wide character is the same in both normal or micro mode.

If the distance moved for a regular character is different in micro mode from the distance moved in normal mode (**mcs<orc**), you can assume the micro mode distance is the same for a wide character printed in micro mode. In this case, you use the **mcs** capability to specify the distance moved. The printer uses the value you specify for both regular and wide characters.

A printer may use control sequences to change the number of columns per inch (the character pitch) and to change the number of lines per inch (the line pitch). If these are used, the resolution of the printer changes but the type of change depends on the printer.

| Capability | Defined as                                                                    |
|------------|-------------------------------------------------------------------------------|
| cpi        | Change character pitch.                                                       |
| cpix       | If set, cpi changes orhi, otherwise the cpi capability changes the orc value. |
| lpi        | Change line pitch                                                             |
| lpix       | If set, lpi changes the orvi value, otherwise the orl value is changed.       |
| chr        | Changes steps per column.                                                     |
| cvr        | Changes steps per line.                                                       |

The **cpi** and **lpi** string capabilities have a single argument, the pitch in columns (or characters) and lines per inch, respectively. The **chr** capability and **cvr** string capabilities each have a single argument, the number of steps per column and line, respectively.

Using any of the control sequences in these strings implies a change in some of the values of the **orc**, **orhi**, **orl**, and **orvi** capabilities. Also, the distance moved when a wide character is printed, specified by the **widcs** capability, changes in relation to the **orc** value. The distance moved when a character is printed in micro mode, **mcs**, changes similarly, with one exception: if the distance is 0 or 1, then no change is assumed.

Programs that use the **cpi**, **lpi**, **chr**, or **cvr** capability should recalculate the printer resolution and should recalculate other values. For more information, see [Effect of Changing Printing Resolution](#).

The following figure, "Specification of Printer Resolution Effects of Changing the Character/Line Pitches" shows the effects on printer resolution before and after a change.

Specification of Printer Resolution  
Effects of Changing the Character/Line Pitches

| <i>Before</i>                     | <i>After</i>                                                  |
|-----------------------------------|---------------------------------------------------------------|
| <i>Using cpi with cpix clear:</i> |                                                               |
| <b>orhi'</b>                      | <b>orhi</b>                                                   |
| <b>orc'</b>                       | $\text{orc} = \frac{\text{orhi}}{V_{cpi}}$                    |
| <i>Using cpi with cpix set:</i>   |                                                               |
| <b>orhi'</b>                      | $\text{orhi} = \text{orc} \cdot V_{cpi}$                      |
| <b>orc'</b>                       | <b>orc</b>                                                    |
| <i>Using lpi with lpix clear:</i> |                                                               |
| <b>orvi'</b>                      | <b>orvi</b>                                                   |
| <b>orl'</b>                       | $\text{orl} = \frac{\text{orvi}}{V_{lpi}}$                    |
| <i>Using lpi with lpix set:</i>   |                                                               |
| <b>orvi'</b>                      | $\text{orvi} = \text{orl} \cdot V_{lpi}$                      |
| <b>orl'</b>                       | <b>orl</b>                                                    |
| <i>Using chr:</i>                 |                                                               |
| <b>orhi'</b>                      | <b>orhi</b>                                                   |
| <b>orc'</b>                       | $V_{chr}$                                                     |
| <i>Using cvr:</i>                 |                                                               |
| <b>orvi'</b>                      | <b>orvi</b>                                                   |
| <b>orl'</b>                       | $V_{cvr}$                                                     |
| <i>Using cpi or chr:</i>          |                                                               |
| <b>widcs'</b>                     | $\text{widcs} = \text{widcs}' \frac{\text{orc}}{\text{orc}'}$ |
| <b>mcs'†</b>                      | $\text{mcs} = \text{mcs}' \frac{\text{orc}}{\text{orc}'}$     |

. This illustration shows the effects of changing characterpitch and line pitch on printer resolution.

$V_{cpi}$ ,  $V_{lpi}$ ,  $V_{chr}$ , and  $V_{cvr}$  are the arguments used with **cpi**, **lpi**, **chr**, and **cvr** respectively. The dagger symbol indicates the old value.

### Capabilities that Cause Movement

In the following descriptions, *movement* refers to the motion of the *current position*. With video terminals this would be the cursor; with some printers this is the carriage position. Other printers have different equivalents. In general, the current position is where a character would be displayed if printed.

The **terminfo** database has string capabilities for control sequences that cause movement a number of full columns or lines. It also has equivalent string capabilities for control sequences that cause movement a number of small steps. The following are the string capabilities for motion:

| Capability             | Description                        |
|------------------------|------------------------------------|
| <b>mcub1</b>           | Move 1 step left.                  |
| <b>mcuf1</b>           | Move 1 step right.                 |
| <b>mcuu1</b>           | Move 1 step up.                    |
| <b>mcud1</b>           | Move 1 step down.                  |
| <b>mcub</b>            | Move <i>N</i> steps left.          |
| <b>mcuf</b>            | Move <i>N</i> steps right.         |
| <b>mcuu</b>            | Move <i>N</i> steps up.            |
| <b>mcud</b>            | Move <i>N</i> steps down.          |
| <b>mhp<sub>a</sub></b> | Move <i>N</i> steps from the left. |
| <b>mvp<sub>a</sub></b> | Move <i>N</i> steps from the top.  |

The last six strings are each used with a single *N* argument.

Sometimes the motion is limited to less than the width or length of a page. Also, some printers do not accept absolute motion to the left of the current position. The following capabilities limit motion:

| Capability   | Description                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------|
| <b>mjump</b> | Limits the use of <b>mcub1</b> , <b>mcuf1</b> , <b>mcuu1</b> , and <b>mcud1</b> capabilities. |
| <b>maddr</b> | Limits the use of the <b>mhp<sub>a</sub></b> and <b>mvp<sub>a</sub></b> capabilities.         |
| <b>xhpa</b>  | If set, the <b>hpa</b> and <b>mhp<sub>a</sub></b> capabilities are negated.                   |
| <b>xvpa</b>  | If set, the <b>vpa</b> and <b>mvp<sub>a</sub></b> capabilities are negated.                   |

If a printer needs to be in *micro mode* for the motion capabilities to work, you can define a string capability to contain the control sequence to enter and exit micro mode. A boolean is available for those printers where using a carriage return causes an automatic return to normal mode. The following capabilities are related to micro mode behavior:

| Capability   | Description                                                           |
|--------------|-----------------------------------------------------------------------|
| <b>smicm</b> | Enter micro mode.                                                     |
| <b>rmicm</b> | Exit micro mode.                                                      |
| <b>crxm</b>  | Using the key specified by the <b>cr</b> capability exits micro mode. |

The movement made when a character is printed in the rightmost position varies among printers. Some make no movement, some move to the beginning of the next line, others move to the beginning of the same line. The **terminfo** database has boolean capabilities that describe all three cases. The **sam** capability specifies that the printer automatically moves to the beginning of the same line after the character is printed in the rightmost margin.

Some printers can be put in a mode where the normal direction of motion is reversed. This mode is especially useful when there exists no capabilities for leftward or upward motion, you can build these capabilities from the motion reversal capability and the rightward or downward motion capabilities. It is best to leave it up to an application to build the leftward or upward capabilities, though, and not enter them into the **terminfo** database. This allows several reverse motions to be strung together without intervening wasted steps that leave and reenter reverse mode. The following capabilities control entering and exiting reverse modes:

| Capability | Description                          |
|------------|--------------------------------------|
| <b>slm</b> | Reverse sense of horizontal motions. |
| <b>rlm</b> | Restore sense of horizontal motions. |
| <b>sum</b> | Reverse sense of vertical motions.   |
| <b>rum</b> | Restore sense of vertical motions.   |

The following capabilities affect the screen while the horizontal motions are reversed:

| Capability   | Description           |
|--------------|-----------------------|
| <b>mcub1</b> | Move 1 step right.    |
| <b>mcuf1</b> | Move 1 step left.     |
| <b>mcub</b>  | Move N steps right.   |
| <b>mcuf</b>  | Move N steps left.    |
| <b>cub1</b>  | Move 1 column right.  |
| <b>cuf1</b>  | Move 1 column left.   |
| <b>cub</b>   | Move N columns right. |
| <b>cuf</b>   | Move N columns left.  |

The following capabilities affect the screen while the vertical motions are reversed:

| Capability   | Description        |
|--------------|--------------------|
| <b>mcuu1</b> | Move 1 step down.  |
| <b>mcud1</b> | Move 1 step up.    |
| <b>mcuu</b>  | Move N steps down. |
| <b>mcud</b>  | Move N steps up.   |
| <b>cuu1</b>  | Move 1 line down.  |
| <b>cud1</b>  | Move 1 line up     |
| <b>cuu</b>   | Move N lines down. |
| <b>cud</b>   | Move N lines up.   |

The reverse motion mode should not affect the **mvp** and **mhp** absolute motion capabilities. The reverse vertical motion mode should, however, also reverse the action of the line *wrapping* that occurs when a character is printed in the right-most position. Thus printers that have the standard **terminfo** capability **am** defined should move to the beginning of the previous line when a character is printed on the right-most position and the printer is in reverse-vertical motion mode.

The action when any other motion capabilities are used in reverse motion modes is not defined. Thus, programs must exit reverse motion modes before using other motion capabilities.

Two miscellaneous capabilities complete the list of new motion capabilities, the **docr** and the **zerom** capability. The **docr** capability provides a list of control characters that cause a carriage return. This capability is useful for printers that move the current position to the beginning of a line when certain control characters, like line-feed or form-feed are used. The **zerom** capability prevents automatic motion after printing a single character. This capability suspends the motion that normally occurs after printing a character.

## Margins

The **terminfo** database provides two strings for setting margins on terminals: one for the left and one for the right margin. Printers, however, have two additional margins for the top and bottom margins of each page. Furthermore, some printers do not require using motion strings to move the current position to a margin and fixing the margin there, as with existing capabilities, but require the specification of where a margin should be regardless of the current position. Therefore, the **terminfo** database offers six additional strings for defining margins with printers. The following capabilities affect margins:

| Capability   | Definition                                      |
|--------------|-------------------------------------------------|
| <b>smgl</b>  | Set left margin at the current column.          |
| <b>smgr</b>  | Set right margin at the current column.         |
| <b>smgb</b>  | Set the soft bottom margin at the current line. |
| <b>smgt</b>  | Set the soft top margin at the current line.    |
| <b>smgbp</b> | Set the soft bottom margin at line <i>N</i> .   |
| <b>smglp</b> | Set the soft left margin at column <i>N</i> .   |
| <b>smgrp</b> | Set the soft right margin at column <i>N</i> .  |
| <b>smgtp</b> | Set soft top margin at line <i>N</i> .          |

The last four strings are used with a single *N* parameter. This parameter specifies a line or column number, where 0 is the top line and column 0 is the left-most column.

**Note:** Not all printers use 0 for the top line or the left-most column.

All margins can be cleared with the **mgc** capability.

### Shadows, Italics, Wide Characters, Superscripts, and Subscripts

Five new sets of strings are used to describe the capabilities that printers have of enhancing printed text. The following define enhanced printing capabilities:

| Capability   | Definition                                    |
|--------------|-----------------------------------------------|
| <b>sshm</b>  | Enter shadow-printing mode.                   |
| <b>rshm</b>  | Exit shadow-printing mode.                    |
| <b>sitm</b>  | Enter italicizing mode.                       |
| <b>ritm</b>  | Exit italicizing mode.                        |
| <b>swidm</b> | Enter wide-character mode.                    |
| <b>rwidm</b> | Exit wide-character mode.                     |
| <b>ssupm</b> | Enter superscript mode.                       |
| <b>rsupm</b> | Exit superscript mode.                        |
| <b>supcs</b> | List of characters available as superscripts. |
| <b>ssubm</b> | Enter subscript mode.                         |
| <b>rsubm</b> | Exit subscript mode.                          |
| <b>subcs</b> | List of characters available as subscripts.   |

If a printer requires the **sshm** control sequence before every character to be shadow-printed, the **rshm** string is left blank. Thus, programs that find a control sequence in **sshm** but none in shadow printing mode should use the control sequence specified by the **sshm** capability before every character to be shadow printed. Otherwise, the control sequence should be used once before the set of characters to be shadow-printed, followed by exiting shadow-printing mode.

The **terminfo** database also has a capability for printing emboldened text, the **bold** capability. While shadow printing and emboldened printing are similar in that they darken the text, many printers produce these two types of print in slightly different ways. Generally emboldened printing is done by overstriking the same character one or more times. Shadow printing likewise usually involves overstriking, but with a slight movement up and/or to the side so that the character is fatter.

It is assumed that enhanced printing modes are independent modes, so that it would be possible, for instance, to shadow print italicized subscripts.

As mentioned earlier, the amount of motion automatically made after printing a wide character should be given in the **widcs** capability.

If only a subset of the printable ASCII characters can be printed as superscripts or subscripts, they should be listed in the **supcs** or **subcs** capabilities, respectively. If the **ssupm** or **ssubm** strings contain control sequences, but the corresponding **supcs** or **subcs** strings are empty, it is assumed that all printable ASCII characters are available as superscripts or subscripts.

Automatic motion made after printing a superscript or subscript is assumed to be the same as for regular characters. For example, printing any of the following result in equivalent motion:

Bi Bi Bi

The boolean capability **msgsr** describes whether an application can use motion control sequences while in standout mode. This capability is extended to cover the enhanced printing modes added here. The **msgsr** capability should be set for those printers that accept any motion control sequences without affecting shadow, italicized, widened, superscript, or subscript printing. Conversely, if the **msgsr** capability is not set, a program should end these modes before attempting any motion.

### Alternate Character Sets

In addition to allowing you to define line graphics, the **terminfo** database also lets you define alternate character sets. The following capabilities cover printers and terminals with multiple selectable or definable character sets:

| Capability   | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>scs</b>   | Select character set <i>N</i> . The <i>N</i> parameter specifies a number from 0 to 63 that identifies a character set.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>scsd</b>  | Start definition of character set <i>N</i> , <i>M</i> characters. The <i>N</i> parameter specifies a number from 0 to 63 that identifies a character set and the <i>M</i> parameter specifies the number of characters in the set.                                                                                                                                                                                                                                                                              |
| <b>defc</b>  | Defines a character <i>A</i> to be <i>B</i> dots wide with a descender <i>D</i> . The <i>A</i> parameter is the ASCII code representation for the character. The <i>B</i> parameter specifies the width of the character in dots. The <i>D</i> parameter specifies whether the character is a descender or not. If the character is a descender, specify a 1 for the <i>D</i> parameter. Otherwise, specify a 1. This string is followed by a string of image-data bytes that describe how the character looks. |
| <b>rcsd</b>  | End definition of character set <i>N</i> . The <i>N</i> parameter specifies a number from 0 to 63 that identifies a character set.                                                                                                                                                                                                                                                                                                                                                                              |
| <b>csnm</b>  | List of character set names.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>daisy</b> | Indicates the printer has manually changed print-wheels.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Character set 0 is the default character set. This is the set that is present after the printer is initialized. Not every printer supports 64 character sets. If you specify a set that a printer does not support, the **tparm** subroutine returns a null result.

If your application must define a character before using it, use the **scsd** control sequence before defining the character set, and the **rcsd** after. If you specify an invalid character set for either of these capabilities, the **tparm** subroutine returns a null resolution. If your application must select a character set after it is defined, the **scs** control sequence should follow the **rcsd** control sequence. By examining the results of using each of the **scs**, **scsd**, and **rcsd** strings with a character set number in a call to the **tparm** subroutine, a program can determine which of the three are needed.

Between use of the **scsd** and **rcsd** strings, the **defc** string should be used to define each character. To print any character on printers defined in the **terminfo** database, the ASCII cod is sent to the printer. This is true for characters in an alternate set as well as *normal* characters. Thus, the definition of a character includes the ASCII code that represents it. In addition, the width of the character includes the ASCII code that represents it. In addition, the width of the character in dots is given, along with tan indication of whether the character is a descender. A descender is a character whose shape extends below the baseline, for example the character g is a descender. The width of the character in dots also indicates the number of image-data bytes that will follow the **defc** string. These image-data bytes indicate where in a dot-matrix pattern ink should be applied to *draw* the character. The number of these bytes and their form are defined below under Dot-Mapped Graphics.

It is easiest for the creator of **terminfo** entries to refer to each character set by number. However, these numbers will be meaningless to the application developer. The **csnm** capability alleviates this problem by providing names for each number.

When used with a character set number in a call to the **tparm** subroutine, the **csnm** capability produces the equivalent name. Use these names as a references only. No naming convention is implied, although anyone who creates a **terminfo** entry for a printer should use names consistent with the names found in user documents for the printer. Application developers should allow a user to specify a character set by number (leaving it up to the user to examine the **csnm** string to determine the correct number), or by name, where the application examines the **csnm** capability to determine the corresponding character set number.

The alternate character set capabilities are likely to be used only with dot-matrix printers. If they are not available, do not define these strings. For printers that have manually changed print-wheels or font cartridges, set the boolean **daisy** capability.

## Dot-Matrix Graphics

Dot-matrix printers typically have the capability to reproduce raster-graphics images. Three new numeric capabilities and three new string capabilities can help a program draw raster-graphic images independent of the type of dot-matrix printer or the number of pins or dots the printer can handle at one time. The dot-matrix capabilities are as follows:

| Capability    | Definition                                                                                                |
|---------------|-----------------------------------------------------------------------------------------------------------|
| <b>npins</b>  | Number of pins $N$ in the print-head. The $N$ parameter specifies the number of pins.                     |
| <b>spinv</b>  | Spacing of pins vertically in pins per inch.                                                              |
| <b>spinh</b>  | Spacing of dots horizontally in dots per inch.                                                            |
| <b>porder</b> | Matches software bits to print-head pins.                                                                 |
| <b>sbim</b>   | Start printing bit image graphics, $B$ bits wide. The $B$ value specifies the width of the image in dots. |
| <b>rbim</b>   | End printing bit image graphics.                                                                          |

The model of dot-matrix or raster-graphics that the **terminfo** database presents is similar to the technique used for most dot-matrix printers. Each pass of the printer's print-head is assumed to produce a dot-matrix that is  $N$  dots high and  $B$  dots wide. This is typically a wide, squat, rectangle of dots. The height of this rectangle in dots varies from one printer to the next. This is given in the **npins** numeric capability. The size of the rectangle in fractions of an inch will also vary. The size can be deduced from the **spinv** and **spinh** numeric capabilities. With these three values an application can divide a complete raster-graphics image into several horizontal strips, perhaps interpolating to account for different dot spacing vertically and horizontally.

The **sbim** and **rbim** capabilities are used to start and end a dot-matrix image, respectively. The **sbim** capability is used with a single argument that gives the width of the dot-matrix in dots. A sequence of image-data bytes are sent to the printer after the **sbim** capability and before the **rbim** string. The number of bytes is an integral multiple of the width of the dot-matrix. The multiple and the form of each byte is determined by the **porder** capability is described below.

The **porder** capability is a comma-separated list of pin numbers. The position of each pin number in the list corresponds to a bit in a data byte. The pins are numbered consecutively from 1 to **npins**, with 1 being the top pin. The term pin is used loosely here. Ink-jet dot matrix printers don't have pins but they do have an equivalent method of applying a single dot of ink to paper. The bit positions in **porder** are in groups of 8, with the first position in each group the most significant bit and the last position the least significant bit.

The image-data bytes are computed from the dot-matrix image, mapping vertical dot positions in each print-head pass into eight-bit bytes, using a 1 bit where ink should be applied and 0 where no ink should

be applied. If a position is skipped in **porder**, a 0 bit is used. There must be a multiple of 8 bit positions used or skipped in **porder**. If not, 0 bits are used to fill the last byte in the least significant bits.

### Effect of Changing Printing Resolution

If the control sequences to change the character pitch or the line pitch are used, the pin or dot spacing may change. The following capabilities change pitch on dot-matrix graphics:

| Capabilities | Definition                                |
|--------------|-------------------------------------------|
| cpi          | Change the character pitch.               |
| cpix         | If set, <b>cpi</b> changes <b>spinh</b> . |
| lpi          | Change line pitch.                        |
| lpix         | If set, <b>lpi</b> changes <b>spinv</b> . |

Programs that use **cpi** or **lpi** should recalculate the dot spacing. The following figure "Dot-Matrix Graphics Effects of Changing the Character/Line Pitches" shows graphics both before and after a change in pitch.

| Dot-Matrix Graphics<br>Effects of Changing the Character/Line Pitches |                                           |
|-----------------------------------------------------------------------|-------------------------------------------|
| Before                                                                | After                                     |
| <i>Using cpi with cpix clear:<br/>spinh'</i>                          | <b>spinh</b>                              |
| <i>Using cpi with cpix set:<br/>spinh'</i>                            | $spinh = spinh' \cdot \frac{orhi}{orhi'}$ |
| <i>Using lpi with lpix clear:<br/>spinv'</i>                          | <b>spinv</b>                              |
| <i>Using lpi with lpix set:<br/>spinv'</i>                            | $spinv = spinv' \cdot \frac{orhi}{orhi'}$ |
| <i>Using chr:<br/>spinh'</i>                                          | <b>spinh</b>                              |
| <i>Using cvr:<br/>spinv'</i>                                          | <b>spinv</b>                              |

Figure 1. Dot-Matrix Graphics. This illustration shows the effects of changing character pitch and line pitch on dot-matrix graphics.

The **orhi'** and **orhi** values are the values of the horizontal resolution in steps per inch, before using **cpi** and after using **cpi**, respectively. Likewise, **orvi'** and **orvi** are the values of the vertical resolution in steps per inch, before using **lpi** and after using **lpi**, respectively. Thus, the changes in the dots per inch for dot-matrix graphics follow the changes in steps per inch for printer resolution.

### Print Quality

Many dot-matrix printers can alter the dot spacing of printed text to produce near letter-quality printing or draft-quality printing. Usually, it is important to be able to choose one or the other because the rate of printing generally falls off as the quality improves. The capabilities that specify print quality are the following:

| Capability   | Definition                     |
|--------------|--------------------------------|
| <b>snlq</b>  | Set near-letter quality print. |
| <b>snrmq</b> | Set normal quality print.      |
| <b>sdrfq</b> | Set draft-quality print.       |

The capabilities are listed in decreasing levels of quality. If a printer does not have all three levels, one or two of the strings should be left blank as appropriate.

### Printing Rate and Buffer Size

Because there is no standard protocol that synchronizes a printer with a program, and because modern printers can buffer data before printing it, a program generally cannot determine at any time what has printed. Two new numeric capabilities can help a program estimate what has printed, the **cps** and **bufsz** capabilities.

The **cps** capability specifies the nominal print rate in characters per second. The **cps** capability is the nominal or average rate at which the printer prints characters. If this value is not given, estimate the rate at one-tenth the prevailing baud rate.

The **bufsz** capability defines a terminal's buffer capacity in characters. The **bufsz** value is the maximum number of subsequent characters buffered before the guaranteed printing of an earlier character, assuming proper flow control was used. If this value is not given it is assumed that the printer does not buffer characters, but prints them as they are received.

As an example, if a printer has a 1000-character buffer, then sending the letter "a" followed by 1000 additional characters is guaranteed to cause the letter "a" to print. If the same printer prints at the rate of 100 characters per second, then it should take 10 seconds to print all the characters in the buffer, less if the buffer is not full. By keeping track of the characters sent to a printer, and knowing the print rate and buffer size, a program can synchronize itself with the printer.

Most printer manufacturers advertise the maximum print rate, not the nominal print rate. A good way to get a value to put in for **cps** is to generate a few pages of text, count the number of printable characters, then see how long it takes to print the text.

Applications that use these values should recognize the variability in the print rate. Straight text, in short lines, with no embedded control sequences will probably print at close to the advertised print rate and probably faster than the rate in **cps**. Graphics data with a lot of control sequences, or very long lines of text, will print at well below the advertised rate and below the rate in **cps**. If the application is using **cps** to decide how long it should take a printer to print a block of text, the application should pad the estimate. If the application is using **cps** to decide how much text has already been printed, it should shrink the estimate. The application errs in favor of the user, who wants, above all, to see all the output in its correct place.

### Database File Names

Compiled **terminfo** file descriptions are placed in subdirectories under the **/usr/share/lib/terminfo** directory to avoid performing linear searches through a single directory containing all of the **terminfo** file description files. A given description file is stored in the **/usr/share/lib/terminfo/c/name** file, where *name* is the name of the terminal, and *c* is the first letter of the terminal name. For example, the compiled description for the terminal **term4-n1** can be found in the file **/usr/share/lib/terminfo/t/term4-n1**. You can create synonyms for the same terminal by making multiple links to the same compiled file. (See the **In** command on how to create multiple links to a file.)

## Example

The following **terminfo** entry describes a terminal:

```

## .tiprc File Format for tip

### Purpose

Provides initial settings of variables for the **tip** command.

### Description

The **.tiprc** file allows you to initialize variable settings for the **tip** command. When first invoked the **tip** command searches the user's home directory (defined by the **\$HOME** environment variable) for a **.tiprc** file. If the file is present, the **tip** command sets the **tip** variables according to instructions in the **.tiprc** file.

The **tip** command uses several different types of variables: numeric, string, character, or Boolean. A Boolean variable can be toggled by putting the variable name in the **.tiprc** file, or it can be reset by putting an ! (exclamation point) in front of the variable name. Other types of variables are set by following the variable name with an = (equal sign) and the new value of the variable.

You can use the **-v** flag of the **tip** command to see the variable settings as they are made. Also, you can use the **~s** escape signal to change variables while the **tip** command is running.

### Examples

Following is a sample **.tiprc** file:

```

be
ba=9600
!echocheck

```

This file toggles the **beautify** (**be**) variable, sets the **baudrate** (**ba**) variable to 9600, and resets the **echocheck** variable to the default setting.

## trcfmt File Format

### Purpose

Stores trace templates.

### Description

The **trcrpt** command, which formats trace reports, uses trace templates to determine how the data contained in trace entries should be formatted. All trace templates are stored in the master template file, **/etc/trcfmt**. Trace templates identify the trace hook ID, the version and release number, the indentation level, the event label, and data description fields. The data description fields contain formatting information for the trace entry data and can be repeated as many times as is necessary to format all of the trace data in the trace entry.

### Modifying this File

The **trcfmt** file should only be modified using the **trcupdate** command. Trace hooks with values less than 010 are for internal use by the trace facilities. If these hooks are changed, the performance of trace, in particular **trcrpt**, is unpredictable.

### Trace Entries

The data that is recorded for each traced event consists of the following elements in the following order:

- A hook word containing a trace hook identifier and the hook type or size.
- A variable number of words of trace data.
- A timestamp.

The organization of the hook word depends on whether the application that produces the hook word is a 32-bit application or a 64-bit application.

32-bit trace hook words:

| Item            | Description                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>HookWord</i> | The first two bytes of a <i>HookWord</i> contain the <i>HookID</i> and <i>HookType</i> . The contents of the second two bytes depends on the value of the <i>HookType</i> .                                                       |
| <i>HookID</i>   | The <i>HookID</i> is represented in the trace entry as 3 hexadecimal digits. For user programs, the hook id may be a value ranging from 0x010 to 0x0FF. <i>HookIDs</i> are defined in the <b>/usr/include/sys/trchkid.h</b> file. |

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>HookType</i> | The <i>HookType</i> is a 4-bit value that identifies the format of the remainder of the trace entry. You specify the <i>HookType</i> when you record the trace entry.                                                                                                                                                                                                              |
| <b>Value</b>    | <b>Trace Entry Format</b>                                                                                                                                                                                                                                                                                                                                                          |
| 1               | The trace entry consists of only the <i>HookWord</i> . The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                                                                       |
| 2               | The trace entry consists of the <i>HookWord</i> and one additional word of trace data. The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                                       |
| 6               | The trace entry consists of the <i>HookWord</i> and up to five additional words of trace data. The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                               |
| 8               | The trace entry consists of the <i>HookWord</i> and a data word followed by a variable number of bytes of trace data and a timestamp. The third and fourth bytes of the <i>HookWord</i> contain the number of bytes of trace data which follows the trace word. Trace entries of this type are recorded using the <b>trcgent</b> subroutine or the <b>trcgenkt</b> kernel service. |
| 9               | The trace entry consists of the <i>HookWord</i> and a timestamp. The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                                                             |
| A               | The trace entry consists of the <i>HookWord</i> , one additional word of trace data, and a timestamp. The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                        |
| E               | The trace entry consists of the <i>HookWord</i> , up to five additional words of trace data, and a timestamp. The third and fourth bytes of the <i>HookWord</i> contain trace data. Trace entries of this type are recorded using the <b>trchook</b> or <b>utrchook</b> subroutine.                                                                                                |
| 0               | The trace entry consists of the <i>HookWord</i> and a data word followed by a variable number of bytes of trace data. The third and fourth bytes of the <i>HookWord</i> contain the number of bytes of trace data which follows the trace word. Trace entries of this type are recorded using the <b>trcgen</b> subroutine or the <b>trcgenk</b> kernel service.                   |

64-bit trace hook words:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>HookWord</i> | The first two bytes of a <i>HookWord</i> contain internal trace meta-data. The second two bytes contain the size of the trace entry minus the hook word and any internal data (such as timestamps or CPU ID). The third two bytes contain the hook ID that can use the full two bytes. A 12-bit hook ID valid in a 32-bit application of the form 0xhhh is equivalent to the 16-bit hook ID 0xhhh0 in a 64-bit application. The last two bytes represent the sub-hook ID.                                                                                                                                 |
| <i>HookID</i>   | The <i>HookID</i> is represented in the trace entry as three or four hexadecimal digits. Four-digit hook IDs are valid only in AIX 6.1 and later releases. For releases earlier than AIX 6.1, the hook ID can be a value ranging from 0x010 to 0xFFFF. For user programs in AIX 6.1 and later releases, the hook ID can be a value ranging from 0x0100 to 0xFFFF. However, if the first hexadecimal digit is zero, the last digit must also be zero. For example, <i>HookID</i> 0AA0 is legal, but 0AAA is not. Many of the AIX system hook IDs are defined in the <i>/usr/include/sys/trchid.h</i> file. |

## Data Pointer

The DATA POINTER is a pointer to the current position in the trace entry. The DATA POINTER is changed by the **trcrpt** as it interprets the template and formats the trace entry. The initial position of the DATA POINTER is the third byte of the *HookWord* for *HookTypes* 1, 9, 2, A, 6, and E and the first byte after the *HookWord* for *HookTypes* 0 and 8.

## Trace Data Formatting

### Indentation Level

The formatted trace data is aligned in columns corresponding to the source of the trace event. This is identified in each template using the **L=X** descriptor. The possible values of the **L=X** command are as

follows:

| Item   | Description                                              |
|--------|----------------------------------------------------------|
| L=APPL | Outputs the trace data in the APPL (application) column. |
| L=SVC  | Outputs the trace data in the SVC (system call) column.  |
| L=KERN | Outputs the trace data in the KERN (kernel) column.      |
| L=INT  | Outputs the trace data in the INT (interrupt)column.     |

## Continuation Character

A \ (backslash) at the end of a line must be used to continue a template on the next line.

## Labels or Text Strings

Individual strings (or labels) can be separated by any number of spaces or tabs, but all excess spacing is compressed to one blank on the trace report unless other format structures are put into effect. Labels are enclosed in double quotes (" ").

| Item | Description                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------|
| \n   | Outputs to a new line. Data on the new line is left-justified according to the value set in the INDENTATION LEVEL. |
| \t   | Inserts a tab. Tabs are expanded to spaces, using a fixed tabstop separation of 8.                                 |

## Format Codes

### DATA POINTER Position Format Codes

| Item | Description                                         |
|------|-----------------------------------------------------|
| Gm.n | Sets DATA POINTER to byte.bit location <i>m.n</i> . |
| Om.n | Advances DATA POINTER by <i>m.n</i> byte.bits.      |
| Rm   | Decrementes DATA POINTER by <i>m</i> bytes.         |

### Output Format Codes

| Item        | Description                                                                                                                                                                                                                                      |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bm.n        | Sends output in Binary format where <i>m</i> is the length of the data in bytes and <i>n</i> is the length in bits. Unlike the other printing format codes, the DATA POINTER can be bit aligned and is not rounded up to the next byte boundary. |
| D2, D4 , D8 | Converts data to signed decimal format. The length of the data is two, four, or eight bytes, and the DATA POINTER is advanced by the same number of bytes.                                                                                       |
| F4          | Converts data to C type 'float' floating point format. The length of the data is 4 bytes, and the DATA POINTER is advanced by 4 bytes.                                                                                                           |
| F8          | Converts data to C type 'double' floating point format. The length of the data is 8 bytes, and the DATA POINTER is advanced by 8 bytes.                                                                                                          |
| S1, S2, S4  | Left-justifies ASCII strings. The length of the string is in the first byte (half-word, word) of the data. The length of the string does not include this byte.                                                                                  |
| T4          | Outputs the next 4 bytes as a date and time string.                                                                                                                                                                                              |
| U2, U4 , U8 | Converts data to unsigned decimal format. The length of the data is two, four, or eight bytes, and the DATA POINTER is advanced by the same number of bytes.                                                                                     |
| Xm          | Converts data to hexadecimal format. The DATA POINTER is advanced by <i>m</i> bytes.                                                                                                                                                             |

### Interpreter Format Codes

| Item       | Description                                                                                                                                                                                                                                                                                    |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E1, E2, E4 | Outputs the next byte (half_word, word) as an 'errno' value, replacing the numeric code with the corresponding #define name in the /usr/include/sys/errno.h file. The DATA POINTER is advanced by 1, 2, or 4 bytes.                                                                            |
| P4         | Uses the next word as a process ID, and outputs the pathname of the executable with that process ID. Process IDs and their pathnames are acquired by the trace command at the start of a trace and by the trcpt command via a special EXEC tracehook. The DATA POINTER is advanced by 4 bytes. |

## Switch Statements

A SWITCH statement is a format code followed by a comma. Each CASE entry of the SWITCH statement consists of:

1. A '*MatchValue*' with a type (usually numeric) corresponding to the format code.
2. A simple '*String*' or a new '*Descriptor*' bounded by braces. A descriptor is a sequence of format codes, strings, switches, and loops.
3. A comma delimiter.

The switch is terminated by a CASE entry without a comma delimiter. The CASE entry is selected as the first entry whose *MatchValue* is equal to the expansion of the format code. The special matchvalue '\\*' is a wildcard and matches anything.

The DATA POINTER is advanced by the format code.

## LOOP Statements

Loops are used to output binary buffers of data; therefore, the descriptor for a LOOP is usually X0 or X1. The syntax of a loop is LOOP format\_code {descriptor}. The descriptor is executed *N* times, where *N* is the numeric value of the format code.

The DATA POINTER is advanced by the format code and by the operations of the descriptor.

## Macros

Macros are temporary variables that work like shell variables. They are assigned a value with the syntax:  
{{ \$xxx = EXPR }}

where EXPR is a combination of format codes, macros, and constants. The operators + (addition), - (subtraction), / (division), and \* (multiplication). are permissible within macros.

### Predefined Macros

| Macro Name    | Description                                                                                                                                                                                                                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$BASEPOINTER | Marks the starting offset into an event. The default is 0, but the actual offset is the sum of the values of DATA POINTER and BASE_POINTER. It is used with template subroutines when the parts of an event have same structure and can be printed by same template but may have different starting points into an event. |
| \$BREAK       | Ends the current trace event.                                                                                                                                                                                                                                                                                             |
| \$D1 - \$D5   | Dataword 1 through dataword 5. The DATA POINTER is not moved.                                                                                                                                                                                                                                                             |
| \$DATAPOINTER | Activates the DATA POINTER. It can be set and manipulated like other user macros.                                                                                                                                                                                                                                         |
| \$DEFAULT     | Uses the DEFAULT template 008.                                                                                                                                                                                                                                                                                            |
| \$ERROR       | Outputs an error message to the report and exit from the template after the current descriptor is processed. The error message supplies the logfile, the logfile offset of the start of that event, and the trace ID.                                                                                                     |
| \$EXECPATH    | Outputs the pathname of the executable for the current process.                                                                                                                                                                                                                                                           |
| \$HB          | Number of bytes in trcgen subroutine variable length buffer. This is also equal to the 16-bit hook data.                                                                                                                                                                                                                  |
| \$HD          | Hook data (lower 16 bits).                                                                                                                                                                                                                                                                                                |

| Macro Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|-------------|---|-----------|---|-----------------------------------|---|-------------------------------------|---|---------------------------|---|-------------------------------------------|---|----------------------------------------------------|
| <b>\$HT</b>                   | Allows for multiple, different <b>trchook</b> subroutine call with the same template. The return values of the <b>\$HT</b> macro are:                                                                                                                                                                                                                                                                                                                                                           |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
|                               | <table border="1"> <thead> <tr> <th>Value</th><th>Description</th></tr> </thead> <tbody> <tr> <td>1</td><td>hook word</td></tr> <tr> <td>2</td><td>hook word and one additional word</td></tr> <tr> <td>6</td><td>hook word and up to five data words</td></tr> <tr> <td>9</td><td>hook word and a timestamp</td></tr> <tr> <td>A</td><td>hook word, one data word, and a timestamp</td></tr> <tr> <td>E</td><td>hook word, up to five data words, and a timestamp.</td></tr> </tbody> </table> | Value | Description | 1 | hook word | 2 | hook word and one additional word | 6 | hook word and up to five data words | 9 | hook word and a timestamp | A | hook word, one data word, and a timestamp | E | hook word, up to five data words, and a timestamp. |
| Value                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
| 1                             | hook word                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |

| <b>\$STOP</b>                 | Immediately ends a trace report.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
| <b>\$SVC</b>                  | Outputs the name of the current system call.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
| <b>\$TID</b>                  | Outputs the current kernel thread ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |
| <b>\$TRACEID</b>              | Returns the trace ID of the current event.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |       |             |   |           |   |                                   |   |                                     |   |                           |   |                                           |   |                                                    |

## Built-in Macros

The built-in macros are:

| Item                                 | Description                                                                                                                                        |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>buftofilename (bp)</b>            | Looks up filename by buf struct.                                                                                                                   |
| <b>fdinstall ()</b>                  | Installs the file descriptor and the current v-node from lookupp as a file_descriptor/v-node pair for this process ID.                             |
| <b>fdtofilename ()</b>               | Looks up the filename for the given file descriptor for this process ID. If the filename is not found, nothing is output.                          |
| <b>flih ()</b>                       | Advances the Interrupt Depth.                                                                                                                      |
| <b>lookupninstall1</b>               | Installs the filename as the current file with the <b>trcrpt</b> command.                                                                          |
| <b>lookupninstall2</b>               | Install the v-node as the current v-node. It also installs the current_v-node/current_file as a v-node/filename par.                               |
| <b>pfsrdwrinstall1 (vp)</b>          | Sets the current v-node of this process to vp.                                                                                                     |
| <b>pfsrdwrinstall2 (VA.S, count)</b> | Creates a virtual address/v-node structure to be filled in be VMM hooks if a page fault occurs.                                                    |
| <b>resume ()</b>                     | Decrement the Interrupt Depth.                                                                                                                     |
| <b>setdelim ()</b>                   | Inhibits spaces between characters.                                                                                                                |
| <b>slihlookup ()</b>                 | Looks up the second level interrupt handler.                                                                                                       |
| <b>sidtofilename (sid)</b>           | Looks up filename by segment ID.                                                                                                                   |
| <b>vmbufinstall ()</b>               | Looks up the v-node of the file through the virtual page/sid and install the v-node and buf as a v-node/bp pair. This will be used by lvm on down. |
| <b>v-nodetofilename (vp)</b>         | Looks up filenames by v-node.                                                                                                                      |
| <b>vpagetofilename (vpage, sid)</b>  | Looks up filenames by vpage and segment ID.                                                                                                        |

## Files

| Item                         | Description               |
|------------------------------|---------------------------|
| /etc/trcfmt                  | Stores trace templates.   |
| /usr/include/sys/trchkid.h   | Defines hook identifiers. |
| /usr/include/sys/trcmacros.h | Defines trace macros.     |

## troff File Format

### Purpose

Describes the output language from the **troff** command.

### Description

The device-independent **troff** file format outputs a pure ASCII description of a typeset document. The description specifies the typesetting device, the fonts, and the point sizes of characters to be used, as well as the position of each character on the page.

A list of all the legal commands follows. Most numbers are denoted by the *Number* variable and are ASCII strings. Strings inside [ ] (brackets) are optional. The **troff** command can produce them, but they are not required for the specification of the language. The \n command character has the standard meaning of new-line character. Between commands, white space has no meaning. White-space characters are spaces and new lines.

The following are the legal commands:

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s <i>Number</i>         | Specifies the point size of the characters to be generated.                                                                                                                                                                                                                                                                                                                                     |
| f <i>Number</i>         | Indicates the font is to be mounted in the position specified by the <i>Number</i> variable value, which ranges from 0 (zero) to the highest font currently mounted. The 0 (zero) value is a special position, called by the <b>troff</b> command, but not directly accessible by the user. Fonts are normally mounted starting at position 1 (one).                                            |
| c <i>Character</i>      | Generates the specified character at the current location on the page; the value specified by the <i>Character</i> variable is a single-byte character.                                                                                                                                                                                                                                         |
| CXYZ                    | Generates the XYZ special character whose name is delimited by white space. The name is one of the special characters legal for the typesetting device as specified in the DESC file. This file resides in a directory specific to the typesetting device. For instruction, see troff Font File Format and the /usr/lib/font/devDevice directory.                                               |
| H <i>Number</i>         | Changes the horizontal position on the page to the number specified. The number is in basic units of motions as specified by the DESC file. This is an absolute <b>goto</b> statement.                                                                                                                                                                                                          |
| h <i>Number</i>         | Adds the number specified to the current horizontal position. This is a relative <b>goto</b> statement.                                                                                                                                                                                                                                                                                         |
| V <i>Number</i>         | Changes the vertical position on the page to the number specified (down is positive).                                                                                                                                                                                                                                                                                                           |
| v <i>Number</i>         | Adds the number specified to the current vertical position.                                                                                                                                                                                                                                                                                                                                     |
| Number <i>Character</i> | This is a two-digit number followed by an single-byte character. The meaning is a combination of the h <i>Number</i> command followed by the c <i>Character</i> command. The specified number is added to the current horizontal position and then the single-byte character, specified by the <i>Character</i> variable, is produced. This is the most common form of character specification. |

| Item                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>nB A</b>                       | Indicates that the end of a line has been reached. No action is required, though by convention the horizontal position is set to 0 (zero). The <b>troff</b> command specifies a resetting of the <i>x,y</i> coordinates on the page before printing more characters. The first number, <i>B</i> , is the amount of space before the line and the second number, <i>A</i> , the amount of space after the line. The second number is delimited by white space. |
| <b>w</b>                          | A <b>w</b> command appears between words of the input document. No action is required. It is included so that one device can be emulated more easily on another device.                                                                                                                                                                                                                                                                                       |
| <b>pNumber</b>                    | Begins a new page. The new page number is included in this command. The vertical position on the page should be set to 0 (zero).                                                                                                                                                                                                                                                                                                                              |
| <b>#...\\n</b>                    | Initiates a comment line with the # (pound sign).                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Dl X Y</b>                     | Draws a line from the current position to that specified by the <i>X,Y</i> variables.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Dc D\\n</b>                    | Draws a circle of the diameter specified by the <i>D</i> variable with the leftmost edge being at the current location ( <i>X,Y</i> ). The current location after drawing the circle is <i>X+D,Y</i> , the rightmost edge of the circle.                                                                                                                                                                                                                      |
| <b>DeDX DY\\n</b>                 | Draws an ellipse with the specified axes. The <i>DX</i> variable is the axis in the <i>X</i> direction and the <i>DY</i> variable is the axis in the <i>Y</i> direction. The leftmost edge of the ellipse is at the current location. After drawing the ellipse, the current location is <i>X+DX,Y</i> .                                                                                                                                                      |
| <b>Da DH1 DV1 DH2 DV2\\n</b>      | Draws a counterclockwise arc from the current position to the <i>DH1+DH2</i> , <i>DV1+DV2</i> variable that has a center of <i>DH1</i> , <i>DV1</i> from the current position. The current location after drawing the arc is at its end.                                                                                                                                                                                                                      |
| <b>D~ X Y X Y ...\\n</b>          | Draws a spline curve (wiggly line) between each of the <i>X,Y</i> coordinate pairs starting at the current location. The final location is the final <i>X,Y</i> pair of the list.                                                                                                                                                                                                                                                                             |
| <b>x P[aper] PaperSize W L\\n</b> | Specifies the name of the paper size to be printed. Valid paper sizes are Letter, Legal, A4, B5, Executive, and A5, where <i>W</i> and <i>L</i> are the paper width and length in machine units.                                                                                                                                                                                                                                                              |
| <b>x i[nit]\\n</b>                | Initializes the typesetting device. The actions required are dependent on the device. An initializing command always occurs before any output generation is attempted.                                                                                                                                                                                                                                                                                        |
| <b>x T Device\\n</b>              | Specifies the name of the typesetter with the <i>Device</i> variable. This is the same as the variable to the -T flag. Information about the typesetter is found in the /usr/lib/font/devDevice directory.                                                                                                                                                                                                                                                    |
| <b>x r[es] N H V\\n</b>           | Specifies the resolution of the typesetting device in increments per inch with the <i>N</i> variable. The <i>H</i> variable specifies units of basic increments that horizontal motion will take place. The <i>V</i> variable indicates the units of basic increments for vertical motion.                                                                                                                                                                    |
| <b>x p[ause]\\n</b>               | Pauses the process by causing the current page to finish but does not relinquish the typesetter.                                                                                                                                                                                                                                                                                                                                                              |
| <b>x s[top]\\n</b>                | Stops the process by causing the current page to finish and then relinquishes the typesetter. Performs any shutdown and bookkeeping procedures required.                                                                                                                                                                                                                                                                                                      |
| <b>x t[railer]\\n</b>             | Generates a trailer. On some devices, no operation is performed.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>x f[ont] N Font\\n</b>         | Loads the specified font into position <i>N</i> .                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>x H[eight] N\\n</b>            | Sets the character height to <i>N</i> points. This causes the letters to be elongated or shortened. It does not affect the width of a letter. Not all typesetters can do this.                                                                                                                                                                                                                                                                                |
| <b>x S[lant] N\\n</b>             | Sets the slant to <i>N</i> degrees. Only some typesetters can do this and not all angles are supported.                                                                                                                                                                                                                                                                                                                                                       |
| <b>x c[codeset] CS\\n</b>         | Switch to codeset <i>CS</i> . For example:<br><b>x codeset IS08859-1</b>                                                                                                                                                                                                                                                                                                                                                                                      |

The following commands are effective on multi-byte characters.

| Item             | Description                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>QC1C2</b>     | Outputs the character specified by the 2 bytes specified by the <i>C1</i> and <i>C2</i> variables. The high-order bits can be set in these bytes.                     |
| <b>RC1C2C3</b>   | Outputs the character specified by the three bytes of the <i>C1</i> , <i>C2</i> , and <i>C3</i> parameters. The high-order bits can be set in these bytes.            |
| <b>SC1C2C3C4</b> | Outputs the character specified by the four bytes of the <i>C1</i> , <i>C2</i> , <i>C3</i> , and <i>C4</i> parameters. The high-order bits can be set in these bytes. |

## Files

| Item                    | Description                                                |
|-------------------------|------------------------------------------------------------|
| /usr/lib/font/devDevice | Contains the DESC file and phototypesetter-specific files. |

troff command

## troff Font File Format

### Purpose

Specifies description files for the **troff** command.

### Description

For each phototypesetter that the **troff** command supports and that is available on your system, there is a directory that contains files describing the phototypesetter and its fonts. This directory is named /usr/lib/font/devName, where the *Name* variable specifies the name of the phototypesetter.

The ASCII **DESC** file in the /usr/lib/font/devName directory within the **troff** command source directory describes the characteristics of the phototypesetter specified by the *Name* variable. A binary version of this file is found in the /usr/lib/font/devName/DESC.out file. Each line of this ASCII file starts with a word that identifies a characteristic, followed by appropriate specifiers. Blank lines and lines beginning with the # (pound sign) are ignored.

For many typesetters, downloaded fonts are supported in a general fashion. The bitmaps for these fonts are stored in the /usr/lib/font/devName/bitmaps directory. Each font size pair is stored in a file with a name of the form *Fontname-Size.pk*. For example:

B-24.pk

These bitmaps are stored in the PK packed-font format used by TeX and its post-processors. These bitmaps are easily generated from readily available programs, such as METAFONT, or easily converted from other forms.

In addition to the bitmap files, a **troff** font file, as described here, is required for each font typeface. In the unitwidth field of this file, the width of each character bitmap in device units is given.

The legal lines for the **DESC** file are:

| Item                            | Description                                                                                                                                                                                                       |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>res</b> Number               | Resolution of device in basic increments per inch.                                                                                                                                                                |
| <b>unitwidth</b> Number         | Point size in which all width tables in the font description files are given. The <b>troff</b> command automatically scales the widths from the <b>unitwidth</b> size to the point size with which it is working. |
| <b>sizescale</b> Number         | Scaling for fractional point sizes. The value of the <i>Number</i> variable is 1. The <b>sizescale</b> line is not currently used.                                                                                |
| <b>paperwidth</b> Number        | Width of paper in basic increments.                                                                                                                                                                               |
| <b>paperlength</b> Number       | Length of paper in basic increments.                                                                                                                                                                              |
| <b>biggestfont</b> Number       | Maximum number of characters in a font.                                                                                                                                                                           |
| <b>sizes</b> Number1 Number2... | List of point sizes available on typesetter, ended by 0.                                                                                                                                                          |
| <b>fonts</b> NumberName...      | Number of initial fonts, followed by the ASCII names of the fonts. For example:<br>fonts 4 R I B S                                                                                                                |

| Item                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>codeset</b> <i>codesetName</i> | Code set for the particular printer or typesetter, where <i>CodesetName</i> is a valid code set name for use with the <b>iconv</b> command. The specified code set is used to define character entries in the charset section of font description files. For example:                                                                                                                                                            |
|                                   | codeset IS08859-1                                                                                                                                                                                                                                                                                                                                                                                                                |
|                                   | The <b>troff</b> command uses the specified <i>CodesetName</i> and the code set implied by the current locale to determine if code set conversions are necessary for the input characters. The <b>iconv</b> function is used to perform the code set conversion if necessary.                                                                                                                                                    |
| <b>charset</b>                    | Last keyword in the file is on a line by itself. Following it is the list of special character names for this device. Names are separated by a space or a new line. The list can be as long as necessary. Names not in this list are not allowed in the font description files.                                                                                                                                                  |
| <b>hor</b> <i>Number</i>          | Smallest unit of horizontal motion.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>vert</b> <i>Number</i>         | Smallest unit of vertical motion.                                                                                                                                                                                                                                                                                                                                                                                                |
|                                   | The <b>hor</b> and <b>vert</b> lines describe the relationships between motions in the horizontal and vertical directions. For example, if the device moves in single basic increments in both directions, both the <b>hor</b> and <b>vert</b> lines have values of 1. If vertical motion occurs only in multiples of two basic units and horizontal motion occurs only in one basic unit, <b>vert</b> is 2 and <b>hor</b> is 1. |

For each font supported by the phototypesetter, there is also an ASCII file with the same name as the font (for instance, **R**, **I**, **CW**) that describes it. The format for a font description file is as follows:

| Item                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>name</b> <i>Name</i>          | Name of the font, such as <b>R</b> or <b>CW</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>internalname</b> <i>Name</i>  | Internal name of the font.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>special</b>                   | Sets the flag indicating that the font is special.                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ligatures</b> <i>Name...0</i> | Sets the flag indicating that the font has ligatures. The list of ligatures follows and is ended by a 0 (zero). Accepted ligatures are <b>ff fi fl ffi ffl</b> .                                                                                                                                                                                                                                                                                                                  |
| <b>spacewidth</b> <i>Number</i>  | Specifies width of space if something other than the default (1/3 of an em space) is desired.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>charset</b>                   | The character set must come at the end. Each line following the <b>charset</b> word describes one character in the font. Each line has one of two formats:<br>Name Width Kerning Code<br>OR<br>Name "                                                                                                                                                                                                                                                                             |
|                                  | where the value of the Name field is either a single-byte character or a special character name from the list found in the <b>DESC</b> file. The Width field is in basic increments. The Kerning field is 1 if the character descends below the line, 2 if it rises above the letter 'a', and 3 if it both rises and descends. The Code field is the number sent to the typesetter to produce the character. For an <b>nls</b> font, the Code field can be a multi-byte sequence. |
|                                  | For fonts of extended-character output devices, the Code field can be a multi-byte sequence that begins and ends with a double quotation mark. In the sequence, control or nonprinting characters can be represented by the following escape sequences:                                                                                                                                                                                                                           |
| \n                               | Produces a new line.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| \r                               | Produces a return.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| \t                               | Produces a tab.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| \b                               | Produces a backspace.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| \"                               | Produces a double quote.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| \xdd                             | Produces a hexadecimal number, where dd is two hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                |

| Item | Description                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \ooo | Produces an octal number, where ooo is three octal digits.                                                                                                                                                                                                                                                                                                                                                                    |
|      | The second format, "Name", is used to show that the character has more than one name. The double quotation marks indicate that this name has the same values as the preceding line. The Kerning and Code fields are not used if the value of the Width field is a double quotation mark. The total number of different characters in this list should not be greater than the value of the biggestfont line in the DESC file. |

The **DESC.out** and **Font.out** files were created as a result of executing the **makedev** program on the **DESC** file.

Prototype characters are provided for the charset section of the font table for fonts in large-character sets. Most characters in large-character sets, such as the Japanese, Chinese, and Korean character sets, have the same width. These prototype characters specify the width of characters with varying byte lengths. The kerning and code fields are not available for prototype character entries. These entries apply to all characters not explicitly defined in the charset section. It is assumed that the printer or typesetter code for characters handled through prototype characters is the same as the input code for the character after conversion by the **iconv** function. The following are the prototype character definitions:

| Item | Description |                                                                     |
|------|-------------|---------------------------------------------------------------------|
| X0   | Width       | Width of all characters that return a value of 0 for <b>csid0</b> . |
| X1   | Width       | Width of all 1-byte characters not defined elsewhere.               |
| X1   | Width       | Width of all characters that return a value of 1 for <b>csid0</b> . |
| X2   | Width       | Width of all 2-byte characters not defined elsewhere.               |
| Xi   | Width       | Width of all characters that return a value of i for <b>csid0</b> . |
| X3   | Width       | Width of all 3-byte characters not defined elsewhere.               |
| X4   | Width       | Width of all 4-byte characters not defined elsewhere.               |

For example, the following prototype character definitions apply to the Japanese character sets (both IBM-932 and IBM-eucJP):

```
X0 : alphanumeric characters
X1 : JIS level 1 and 2 Kanji characters in JISX0208.1990
X2 : Katakana characters
X3 : IBM selected characters
```

## Files

| Item                                    | Description                                                                                   |
|-----------------------------------------|-----------------------------------------------------------------------------------------------|
| /usr/lib/font/devName/DESC.out file     | Contains the description file for phototypesetter specified by the <i>Name</i> variable.      |
| /usr/lib/font/devName/bitmaps directory | Contains bitmap files.                                                                        |
| /usr/lib/font/devName/Font.out file     | Contains the font description file for phototypesetter specified by the <i>Name</i> variable. |

## tunables File Format

### Purpose

Centralizes tunable parameter values.

### Description

Tunables files contain one or more sections, called "stanzas". A stanza is started by a line containing the stanza name followed by a colon (:). There is no marking for the end of a stanza. It simply continues until another stanza starts. Each stanza contains a set of parameter/value pairs; one pair per line. The values are surrounded by double quotes ("), and an equal sign (=) separates the parameter name from its value. A parameter/value pair must necessarily belong to a stanza. It has no meaning outside of a stanza. Two parameters sharing the same name but belonging to different stanzas are considered to be different parameters. If a parameter appears several times in a stanza, only its first occurrence is used. Following occurrences are simply ignored. Similarly, if a stanza appears multiple times in the file, only the first occurrence is used. Everything following a number sign (#) is considered a comment and ignored. Heading and trailing blanks are also ignored.

A tunable file uses the following syntax:

```
first stanza
stanza1:
 param1 = "value1"
 param2 = "value2"
 param2 = "value3" # ignored, since already defined

another stanza
stanza2:
 param1 = "value4" # not the same parameter as param1 in stanza1

the first stanza again
stanza1: # ignored since already defined
```

Tunables files currently support seven different stanzas: one for each of the tunable commands (**schedo**, **vmo**, **ioo**, **raso**, **no** and **nfso**), plus a special **info** stanza. The six stanzas, **schedo**, **vmo**, **ioo**, **raso**, **no** and **nfso** contain tunable parameters managed by the corresponding command. For the complete parameter lists, see the display resulting from running the corresponding command lines specifying the **-a** or **-L** option.

The value of the tunable can be either a numerical value or the following literal words:

#### DEFAULT

This tunable's default value.

#### STATIC

A Static variable that is never restored.

#### RESTRICTED

The value for restricted tunables that have been modified so that the value is not the default value.

It is possible that a stanza contains values for non-existent parameters (in the case a tunable file was copied from a machine running an older version of AIX and one or more tunables do not exist anymore). Both the **tunrestore** and the **tuncheck** commands will print warnings about such parameters.

The **info** stanza is used to store information about the purpose of the tunable file and the level of AIX on which it was validated. Any parameter is acceptable in this stanza, however, some fields have a special meaning:

| Item             | Description                                                                                                                                                                                                                                                                                                        |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description      | A character string describing the tunable file. SMIT displays this field in the file selection box.                                                                                                                                                                                                                |
| AIX_level        | AIX version. This field is automatically updated by <b>tunsave</b> and <b>tuncheck</b> (on success only).                                                                                                                                                                                                          |
| Kernel_type:     | MP64" this is a 64 bits multiprocessor kernel.This field is automatically updated by <b>tunsave</b> and <b>tuncheck</b> (on success only).                                                                                                                                                                         |
| Last_validation  | The date this file was validated for the last time, and the type of validation: "current" the file has been validated against the current context. "reboot" the file has been validated against the nextboot context. This field is automatically updated by <b>tunsave</b> and <b>tuncheck</b> (on success only). |
| LogFile_checksum | The checksum of the <b>lastboot.log</b> file matching this <b>tunables</b> file. This field is present only in the <b>lastboot</b> file.                                                                                                                                                                           |

Other stanzas like **info**, **schedo**, **vmo**, **i00**, **raso**, **no** and **nfso** may be present. These stanzas are simply ignored by the **tunrestore** command, but flagged by the **tuncheck** command.

Three files under /etc/tunables have special names and meaning:

| Item         | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nextboot     | This file is automatically applied at boot time. The <b>bosboot</b> command also get the value of Bosboot types tunables from this file. It contains all tunable settings made permanent.                                                                                                                                                                                                                                |
| lastboot     | This file is automatically generated at boot time. It contains the full set of tunable parameters, with their values after the last boot. Default values are marked with # DEFAULT VALUE. Restricted tunables that have been modified are marked with # RESTRICTED not at default value.                                                                                                                                 |
| lastboot.log | This should be the only file in <b>/etc/tunables</b> that is not in the stanza format described here. It is automatically generated at boot time, and contains the logging of the creation of the <b>lastboot</b> file, i.e. any parameter change made is logged. Any change which could not be made (possible if the <b>nextboot</b> file was created manually and not validated with <b>tuncheck</b> ) is also logged. |

## Examples

The following is a sample **tunables** file:

```

info:
 Description = "Set of tunables for departmental server"
 AIX_level = "5.2.0.0"
 Kernel_type = "UP"
 Last_validation = "2002-06-16 12:11:11 CDT current"

schedo:
 timeslice = "2" # set timeslice to 30ms
 sched_D = "DEFAULT" # value was 123

vmo:
 minperm = "48538"
 memory_frames = "65536" # STATIC (never restored)

i00:
 iotunable = "value"

no:
 ipforwarding = "1"
 ipsrcrouteforward = "1"
 thewall = "STATIC" # value was 131072 (never restored)

nfso:
 nfs_allow_all_signals = "0" # DEFAULT VALUE
 nfs_device_specific_bufs = "0"

raso:
 recovery_framework = "0" # RESTRICTED not at default value
 recovery_debugger = "0" # DEFAULT VALUE

```

## Files

All the tunable files are located in the **/etc/tunables** directory.

| Item                              | Description                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------|
| <b>/etc/tunables/nextboot</b>     | Contains the values to be applied at the next rebooting of the machine.                                          |
| <b>/etc/tunables/lastboot</b>     | Contains the values for all tuning parameters after the last rebooting of the machine.                           |
| <b>/etc/tunables/lastboot.log</b> | Contains logging information about changes made and errors encountered during the last rebooting of the machine. |

## uconvdef Source File Format

### Purpose

Defines UCS-2 (Unicode) conversion mappings for input to the **uconvdef** command.

### Description

Conversion mapping values are defined using UCS-2 symbolic character names followed by character encoding (code point) values for the multibyte code set. For example,

<U0020> \x20

represents the mapping between the <U0020> UCS-2 symbolic character name for the space character and the \x20 hexadecimal code point for the space character in ASCII.

In addition to the code set mappings, directives are interpreted by the **uconvdef** command to produce the compiled table. These directives must precede the code set mapping section. They consist of the following keywords surrounded by < > (angle brackets), starting in column 1, followed by white space and the value to be assigned to the symbol:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code_set_name>  | The name of the coded character set, enclosed in quotation marks (" "), for which the character set description file is defined.                                                                                                                                                                                                                                                                               |
| <mb_cur_max>     | The maximum number of bytes in a multibyte character. The default value is 1.                                                                                                                                                                                                                                                                                                                                  |
| <mb_cur_min>     | An unsigned positive integer value that defines the minimum number of bytes in a character for the encoded character set. The value is less than or equal to <mb_cur_max>. If not specified, the minimum number is equal to <mb_cur_max>.                                                                                                                                                                      |
| <escape_char>    | The escape character used to indicate that the character following is interpreted in a special way. This defaults to a backslash (\).                                                                                                                                                                                                                                                                          |
| <comment_char>   | The character that, when placed in column 1 of a <b>charmap</b> line, is used to indicate that the line is ignored. The default character is the number sign (#).                                                                                                                                                                                                                                              |
| <char_name_mask> | A quoted string consisting of format specifiers for the UCS-2 symbolic names. This must be a value of AXXXX, indicating an alphabetic character followed by 4 hexadecimal digits. Also, the alphabetic character must be a U, and the hexadecimal digits must represent the UCS-2 code point for the character. An example of a symbolic character name based on this mask is <U0020> Unicode space character. |

| Item          | Description                                                                                                                                                                                   |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <uconv_class> | Specifies the <b>type</b> of the code set. It must be one of the following:                                                                                                                   |
|               | <b>SBCS</b> Single-byte encoding                                                                                                                                                              |
|               | <b>DBCS</b> Stateless double-byte, single-byte, or mixed encodings                                                                                                                            |
|               | <b>EBCDIC_STATEFUL</b><br>Stateful double-byte, single-byte, or mixed encodings                                                                                                               |
|               | <b>MBCS</b> Stateless multibyte encoding                                                                                                                                                      |
|               | This <b>type</b> is used to direct <b>uconvdef</b> on what type of table to build. It is also stored in the table to indicate the type of processing algorithm in the UCS conversion methods. |
| <locale>      | Specifies the default locale name to be used if locale information is needed.                                                                                                                 |
| <subchar>     | Specifies the encoding of the default substitute character in the multibyte code set.                                                                                                         |

The mapping definition section consists of a sequence of mapping definition lines preceded by a **CHARMAP** declaration and terminated by an **END CHARMAP** declaration. Empty lines and lines containing <comment\_char> in the first column are ignored.

Symbolic character names in mapping lines must follow the pattern specified in the <char\_name\_mask>, except for the reserved symbolic name, <unassigned>, that indicates the associated code points are unassigned.

Each noncomment line of the character set mapping definition must be in one of the following formats:

1. "%s %s %s/n", <symbolic-name>, <encoding>, <comments>

For example:

<U3004> \x81\x57

This format defines a single symbolic character name and a corresponding encoding.

The encoding part is expressed as one or more concatenated decimal, hexadecimal, or octal constants in the following formats:

- "%cd%d", <escape\_char>, <decimal byte value>
- "%cx%x", <escape\_char>, <hexadecimal byte value>
- "%c%o", <escape\_char>, <octal byte value>

Decimal constants are represented by two or more decimal digits preceded by the escape character and the lowercase letter **d**, as in \d97 or \d143. Hexadecimal constants are represented by two or more hexadecimal digits preceded by an escape character and the lowercase letter **x**, as in \x61 or \x8f.

Octal constants are represented by two or more octal digits preceded by an escape character.

Each constant represents a single-byte value. When constants are concatenated for multibyte character values, the last value specifies the least significant octet and preceding constants specify successively more significant octets.

2. "%s...%s %s/n", <symbolic-name>, <symbolic-name>, <encoding>, <comments>

For example:

<U3003>...<U3006> \x81\x56

This format defines a range of symbolic character names and corresponding encodings. The range is interpreted as a series of symbolic names formed from the alphabetic prefix and all the values in the range defined by the numeric suffixes.

The listed encoding value is assigned to the first symbolic name, and subsequent symbolic names in the range are assigned corresponding incremental values. For example, the line:

<U3003>...<U3006> \x81\x56

is interpreted as:

```
<U3003> \x81\x56
<U3004> \x81\x57
<U3005> \x81\x58
<U3006> \x81\x59
```

3. "<unassigned> %s. . .%s %s/n", <encoding>, <encoding>, <comments>

This format defines a range of one or more unassigned encodings. For example, the line:

```
<unassigned> \x9b...\x9c
```

is interpreted as:

```
<unassigned> \x9b
<unassigned> \x9c
```

## UIL File Format

### Purpose

Contains information on the user interface for a widget-based application.

### Description

User Interface Language (UIL) is used to describe the initial state of a user interface for a widget-based application. UIL describes the widgets used in the interface, the resources of those widgets, and the callbacks of those widgets. A UIL file is compiled into a user interface definition (UID) file using the **uil** command or the **Uil** callable compiler function. The contents of the compiled UID file can then be accessed by the various Motif Resource Manager (MRM) functions from within an application program.

The syntax for the UIL is as follows:

```
MODULE ModuleName [NAMES = CASE_INSENSITIVE | CASE_SENSITIVE] [CHARACTER_SET = CharacterSet] [OBJECTS = { WidgetName = GADGET | WIDGET; [...] }] { [[ValueSection] | [ProcedureSection] | [ListSection] | [ObjectSection] | [IdentifierSection] | [...]] } END MODULE;
```

### File Format

UIL is a free-form language. This means that high-level constructs, such as object and value declarations, do not need to begin in any particular column and can span any number of lines. Low-level constructs, such as keywords and punctuation characters, can also begin in any column; however, except for string literals and comments, they cannot span lines.

The UIL compiler accepts input lines up to 132 characters in length.

| Item                     | Description                                                                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MODULE <i>ModuleName</i> | The name by which the UIL module is known in the UID file. This name is stored in the UID file for later use in the retrieval of resources by the MRM. This module name is always uppercase. |

| Item                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAMES = CASE_INSENSITIVE   CASE_SENSITIVE</b>          | Indicates whether names should be treated as case-sensitive or case-insensitive. The default is case-sensitive. The case-sensitivity clause should be the first clause in the module header and must precede any statement that contains a name. If names are case-sensitive in a UIL module, UIL keywords in that module must be in lowercase. Each name is stored in the UIL file in the same case as it appears in the UIL module. If names are case-insensitive, keywords can be in uppercase, lowercase, or mixed case, and the uppercase equivalent of each name is stored in the UID file.                                                                                     |
| <b>CHARACTER_SET = <i>CharacterSet</i></b>                | Specifies the default character set for string literals in the module that do not explicitly set their character set. In the absence of this clause, the default character set is the codeset component of the LANG environment variable, or the value of <b>XmFALLBACK_CHARSET</b> if LANG is not set or has no codeset component. The value of <b>XmFALLBACK_CHARSET</b> is defined by the UIL supplier, but is usually <b>ISO8859-1</b> (equivalent to <b>ISO_LATIN1</b> ). Use of this clause turns off all localized string literal processing turned on by either the <b>-s</b> compiler flag or the <b>UiL_command_type</b> data structure element <b>use_setlocale_flag</b> . |
| <b>OBJECTS = { <i>WidgetName</i> = GADGET   WIDGET; }</b> | Indicates whether the widget or gadget form of the control specified by <i>WidgetName</i> variable is used by default. The widget form is used by default. The specified control should be one that has both a widget and gadget version, for example: <b>XmCascadeButton</b> , <b>XmLabel</b> , <b>XmPushButton</b> , <b>XmSeparator</b> , and <b>XmToggleButton</b> . The form of more than one control can be specified by delimiting them with ; (semicolons). The gadget or widget form of an instance of a control can be specified with the <b>GADGET</b> and <b>WIDGET</b> keywords in a particular object declaration.                                                       |
| <i>ValueSection</i>                                       | Provides a way to name a value expression or literal. The value name can then be referred to by declarations that occur elsewhere in the UIL module in any context where a value can be used. Values can be forward-referenced. See "Value Sections" for more detail.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>ProcedureSection</i>                                   | Defines the callback functions used by a widget and the creation functions for user-defined widgets. These definitions are used for error checking. See "Procedure Sections" for more detail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>ListSection</i>                                        | Provides a way to group together a set of arguments, controls (children), callbacks, or procedures for later use in the UIL module. Lists can contain other lists so you can set up a hierarchy to clearly show which arguments, controls, callbacks, and procedures are common to which widgets. See "List Sections" for more detail.                                                                                                                                                                                                                                                                                                                                                |
| <i>ObjectSection</i>                                      | Defines the objects that make up the user interface of the application. You can reference the object names in declarations that occur elsewhere in the UIL module in any context where an object name can be used (for example, in a controls list, as a symbolic reference to a widget ID, or as the <i>TagValue</i> argument for a callback procedure). Objects can be forward-referenced. See "Object Sections" for more detail.                                                                                                                                                                                                                                                   |
| <i>IdentifierSection</i>                                  | Defines a run-time binding of data to names that appear in the UIL module. See "Identifier Sections" for more detail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

The UIL file can also contain comments and include directives. These, as well as the main elements of the UIL file format, are described in the following sections.

## Comments

Comments can take one of two forms, neither of which can be nested:

- The comment is introduced with the /\* sequence followed by the text of the comment and terminated with the \*/ sequence. This form of comment can span multiple source lines.

- The comment is introduced with an ! (exclamation point) followed by the text of the comment and terminated by the end of the source line.

## Value Sections

A value section consists of the **VALUE** keyword followed by a sequence of value declarations. It has the following syntax:

**VALUE** *ValueName* : [ **EXPORTED** | **PRIVATE** ] *ValueExpression* | **IMPORTED** *ValueType* ;

*ValueExpression* is assigned to *ValueName*, or a *ValueType* is assigned to an imported value name. A value declaration provides a way to name a value expression or literal. The value name can be referred to by declarations that occur later in the UIL module in any context where a value can be used. Values can be forward-referenced.

| Item            | Description                                                                                                                                                                                                                                                                                                                                                    |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EXPORTED</b> | A value that you define as exported is stored in the UID file as a named resource and can be referenced by name in other UID files. When you define a value as exported, MRM looks outside the module in which the exported value is declared to get its value at run time.                                                                                    |
| <b>PRIVATE</b>  | A private value is a value that is not imported or exported. A value that you define as private is not stored as a distinct resource in the UID file. You can reference a private value only in the UIL module containing the value declaration. The value or object is directly incorporated into anything in the UIL module that references the declaration. |
| <b>IMPORTED</b> | A value that you define as imported is one that is defined as a named resource in a UID file. MRM resolves this declaration with the corresponding exported declaration at application run time.                                                                                                                                                               |

By default, values and objects are private. The following is a list of the supported value types in UIL:

- **ANY**
- **ARGUMENT**
- **BOOLEAN**
- **COLOR**
- **COLOR\_TABLE**
- **COMPOUND\_STRING**
- **FLOAT**
- **FONT**
- **FONT\_TABLE**
- **FONTSET**
- **ICON**
- **INTEGER**
- **INTEGER\_TABLE**
- **KEYSYM**
- **REASON**
- **SINGLE\_FLOAT**
- **STRING**
- **STRING\_TABLE**
- **TRANSLATION\_TABLE**
- **WIDE\_CHARACTER**
- **WIDGET**

## Procedure Sections

A procedure section consists of the **PROCEDURE** keyword followed by a sequence of procedure declarations. It has the following syntax:

```
PROCEDURE ProcedureName [([ValueType])] ;
```

Use a procedure declaration to declare the following:

- A function that can be used as a callback function for a widget
- The creation function for a user-defined widget.

You can reference a procedure name in declarations that occur later in the UIL module in any context where a procedure can be used. Procedures can be forward-referenced. You *cannot* use a name that you used in another context as a procedure name.

In a procedure declaration, you have the option of specifying that a parameter is passed to the corresponding callback function at run time. This parameter is called the *callback tag*. You can specify the data type of the callback tag by putting the data type in parentheses following the procedure name. When you compile the module, the UIL compiler checks that the argument you specify in references to the procedure is of this type. Note that the data type of the callback tag must be one of the valid UIL data types. You can use a widget as a callback tag, as long as the widget is defined in the same widget hierarchy as the callback; that is, they must have a common ancestor that is in the same UIL hierarchy.

The following list summarizes how the UIL compiler checks argument type and argument count, depending on the procedure declaration:

| Item          | Description                                                                                                                              |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------|
| No parameters | No argument type or argument count checking occurs. You can supply either 0 or 1 arguments in the procedure reference.                   |
| ()            | Checks that the argument count is 0.                                                                                                     |
| (ANY)         | Checks that the argument count is 1. Does not check the argument type. Use the ANY data type to prevent type checking on procedure tags. |
| (Type)        | Checks for one argument of the specified type.                                                                                           |
| (ClassName)   | Checks for one widget argument of the specified widget class.                                                                            |

While it is possible to use any UIL data type to specify the type of a tag in a procedure declaration, you must be able to represent that data type in the programming language you are using. Some data types (such as integer, Boolean, and string) are common data types recognized by most programming languages. Other UIL data types (such as string tables) are more complicated and may require you to set up an appropriate corresponding data structure in the application in order to pass a tag of that type to a callback function.

You can also use a procedure declaration to specify the creation function for a user-defined widget. In this case, you specify no formal parameters. The procedure is called with the standard three arguments passed to all widget creation functions.

## List Sections

A list section consists of the **LIST** keyword followed by a sequence of list declarations. It has the following syntax:

```
LIST ListName : { ListItem; [...] } [...]
```

You can also use list sections to group together a set of arguments, controls (children), callbacks, or procedures for later use in the UIL module. Lists can contain other lists so you can set up a hierarchy to clearly show which arguments, controls, callbacks, and procedures are common to which widgets. You cannot mix the different types of lists; a list of a particular type cannot contain entries of a different list

type or reference the name of a different list type. A list name is always private to the UIL module in which you declare the list and cannot be stored as a named resource in a UID file.

The additional list types are described in the following sections.

### Arguments List Structure

An arguments list defines which arguments are specified in the arguments-list parameter when the creation function for a particular object is called at run time. An arguments list also specifies the values for those arguments. Arguments lists have the following syntax:

**LIST** *ListName* : **ARGUMENTS** { *ArgumentName* = *ValueExpression*; [...] } [...]

The argument name (*ArgumentName*) must be either a built-in argument name or a user-defined argument name that is specified with the **ARGUMENTS** function.

If you use a built-in argument name as an arguments list entry in an object definition, the UIL compiler checks the argument name to be sure that it is supported by the type of object that you are defining. If the same argument name is displayed more than once in a given arguments list, the last entry that uses that argument name supersedes all previous entries with that name, and the compiler issues a message.

Some arguments, such as **XmNItems** and **XmNItemCount**, are coupled by the UIL compiler. When you specify one of the coupled arguments, the compiler also sets the other one. The coupled argument is not available to you.

AIXwindows and the X Toolkit (Intrinsics) support *constraint arguments*. A constraint argument is one that is passed to children of an object, beyond those arguments normally available. For example, the **Form** widget grants a set of constraint arguments to its children. These arguments control the position of the children within the **Form** widget.

Unlike the arguments used to define the attributes of a particular widget, constraint arguments are used exclusively to define additional attributes of the children of a particular widget. These attributes affect the behavior of the children within their parent. To supply constraint arguments to the children, include the arguments in the arguments list for the child.

### Callbacks List Structure

Use a callbacks list to define which callback reasons are to be processed by a particular widget at run time. Callback lists have the following syntax:

**LIST** *ListName* : **CALLBACKS** { *ReasonName* = **PROCEDURE** *ProcedureName* [ ( [ *ValueExpression* ] ) ]; | *ReasonName* = *ProcedureList* ; [...] } [...]

For AIXwindows widgets, the reason name must be a built-in reason name. For a user-defined widget, you can use a reason name that you previously specified using the **REASON** function. If you use a built-in reason in an object definition, the UIL compiler ensures that reason is supported by the type of object you are defining.

If the same reason is displayed more than once in a callbacks list, the last entry referring to that name supersedes all previous entries using the same reason. The UIL compiler then issues a diagnostic message.

If you specify a named value for the procedure argument (callback tag), the data type of the value must match the type specified for the callback tag in the corresponding procedure declaration. When specifying a widget name as a procedure value expression, you must also specify the type of the widget and a space before the name of the widget.

Because the UIL compiler produces a UID file rather than an object module (.o), the binding of the UIL name to the address of the entry point and then to the procedure is not done by the loader. Instead, this binding is established at run time with the **MrmRegisterNames** MRM function. You call this function before fetching any objects, giving it both the UIL names and the procedure addresses of each callback. The name you register with MRM in the application program must match the name you specified for the procedure in the UIL module.

Each callback procedure received three arguments. The first two arguments have the same form for each callback. The form of the third argument varies from object to object.

The first argument is the address of the data structure maintained by the AIXwindows for this object instance. This address is called the widget ID for this object.

The second argument is the address of the value you specified in the callbacks list for this procedure. If you do not specify an argument, the address is null.

The third argument is the reason name you specified in the callbacks list.

### Controls List Structure

A controls list defines which objects are children of, or controlled by, a particular object. Each entry in a controls list has the following syntax:

**LIST** *ListName* : **CONTROLS** { [ *ChildName*] [**MANAGED** | **UNMANAGED**] *ObjectDefinition*; [...] } [...]

If you specify the **MANAGED** keyword at run time, the object is created and managed; if you specify the **UNMANAGED** keyword at run time, the object is only created. Objects are managed by default.

You can use the *ChildName* parameter to specify resources for the automatically created children of a particular control. Names for automatically created children are formed by appending **Xm\_** to the name of the child widget. This name is specified in the documentation for the parent widget.

Unlike the arguments list and the callbacks list, a controls list entry that is identical to a previous entry does *not* supersede the previous entry. At run time, each controls list entry causes a child to be created when the parent is created. If the same object definition is used for multiple children, multiple instances of the child are created at run time.

### Procedures List Structure

You can specify multiple procedures for a callback reason in UIL by defining a procedures list. Just as with other list types, procedures lists can be defined in-line or in a list section and referenced by name.

If you define a reason more than once (for example, when the reason is defined both in a referenced procedures list and in the callbacks list for the object), previous definitions are overridden by the latest definition. The syntax for a procedures list is as follows:

**LIST** *ListName* : **PROCEDURES** { *ProcedureName* [ ( [ *ValueExpression* ] ) ]; [...] } [...]

When specifying a widget name as a procedure value expression, you must also specify the type of the widget and a space before the name of the widget.

### Object Sections

An object section consists of the **OBJECT** keyword followed by a sequence of object declarations. It has the following syntax:

**OBJECT** *ObjectName* : [ **EXPORTED** | **PRIVATE** | **IMPORTED** ] *ObjectType* [ **PROCEDURE** *CreationFunction* ] [ *ObjectName* [ **WIDGET** | **GADGET** ] | { *ListDefinitions* } ]

Use an object declaration to define the objects that are stored in the UID file. You can reference the object name in declarations that occur elsewhere in the UIL module in any context where an object name can be used (for example, in a controls list, as a symbolic reference to a widget ID, or as the *TagValue* argument for a callback procedure). Objects can be *forward-referenced*, meaning that you can declare an object name after you have referenced it. All references to an object name must be consistent with the type of the object, as specified in the object declaration. You can specify an object as exported, imported, or private.

The object definition can contain a sequence of lists that define the arguments, hierarchy, and callbacks for the widget. You can only specify one list of each type for an object. When you declare a user-defined widget, you must include a reference to the widget creation function for the user-defined widget.

Use the **GADGET** or **WIDGET** keyword to specify the object type or to override the default variant for this object type. You can use the AIXwindows name of an object type that has a gadget variant (for example, **XmLabelGadget**) as an attribute of an object declaration. The *ObjectType* can be any object type, including gadgets. You need to specify the **GADGET** or **WIDGET** keyword only in the declaration of an object, not when you reference the object. You *cannot* specify the **GADGET** or **WIDGET** keyword for a user-defined object; user-defined objects are always widgets.

### Identifier Sections

The identifier section allows you to define an *identifier*, a mechanism that achieves run-time binding of data to names that appear in a UIL module. The identifier section consists of the reserved **IDENTIFIER** keyword, followed by a list of names. Each name is followed by a semicolon (;). The syntax is as follows:

**IDENTIFIER** *IdentifierName*; [...];

You can use these names later in the UIL module as either the value of an argument to a widget or the tag value to a callback procedure. At run time, use the **MrmRegisterNames** and **MrmRegisterNamesInHierarchy** MRM functions to bind the identifier name with the data (or, in the case of callbacks, with the address of the data) associated with the identifier.

Each UIL module has a single name space; therefore, you cannot use the name you used for a value, object, or procedure as an identifier name in the same module.

The UIL compiler does not do any type checking on the use of identifiers in a UIL module. Unlike a UIL value, an identifier does not have a UIL type associated with it. Regardless of what particular type a widget argument or callback procedure tag is defined to be, you can use an identifier in that context instead of a value of the corresponding type.

To reference these identifier names in a UIL module, use the name of the identifier wherever you want its value to be used.

### Include Directives

The include directive incorporates the contents of a specified file into a UIL module. This mechanism allows several UIL modules to share common definitions. The syntax for the include directive is as follows:

**INCLUDE FILE** *FileName* ;

The UIL compiler replaces the include directive with the contents of the include file and processes it as if these contents were displayed in the current UIL source file.

You can nest include files, meaning that an include file can contain include directives. The UIL compiler can process up to 100 references (including the file containing the UIL module). Therefore, you can include up to 99 files in a single UIL module, including nested files. Each time a file is opened counts as a reference; therefore, including the same file twice counts as two references.

The character expression is a file specification that identifies the file to be included. The rules for finding the specified file are similar to the rules for finding header, or .h, files using the include directive, #include, with a quoted string in C language. The uil command uses the -I option for specifying a search directory for include files. Search rules are as follows:

- If you supply a directory, the UIL compiler searches only that directory for the include file.
- If you do not supply a directory, the UIL compiler searches for the include file in the directory of the main source file.
- If the include file is not found in the main source file directory, the compiler looks in the same directory as the source file.

## Language Syntax

This section contains information on the following:

- Names and Strings
- Data Types
- String Literals
- Integer Literals
- Boolean Literals
- Floating-Point Literals
- ANY Data Type
- Expressions
- Functions.

### Names and Strings

Names can consist of any of the characters A to Z, a to z, 0 to 9, \$ (dollar sign), and \_ (underscore). Names cannot begin with a digit (0 to 9). The maximum length of a name is 31 characters.

UIL gives you a choice of either case-sensitive or case-insensitive names through a clause in the MODULE header. For example, if names are case-sensitive, the names "sample" and "Sample" are distinct from each other. If names are case-insensitive, these names are treated as the same name and can be used interchangeably. By default, UIL assumes names are case-sensitive.

In case-insensitive mode, the compiler outputs all names in the UID file in uppercase form. In case-sensitive mode, names are displayed in the UIL file exactly as they are displayed in the source file.

The following lists the reserved keywords, which *cannot* be used for programmer-defined names:

Table 10. Reserved Keywords

| Item      | Description | Description |
|-----------|-------------|-------------|
| ARGUMENTS | CALLBACKS   | CONTROLS    |
| END       | EXPORTED    | FALSE       |
| GADGET    | IDENTIFIER  | INCLUDE     |
| LIST      | MODULE      | OFF         |
| ON        | OBJECT      | PRIVATE     |
| PROCEDURE | PROCEDURES  | TRUE        |
| VALUE     | WIDGET      |             |

The following lists UIL unreserved keywords. These keywords can be used as programmer-defined names; however, if you use any of these keywords as names, you cannot use the UIL-supplied form of that keyword.

Built-in argument names (for example, **XmNx**, **XmNheight**) Built-in reason names (for example, **XmActivateCallback**, **XmNhelpCallback**) Character set names (for example, **ISO\_LATIN1**, **ISO\_HEBREW\_LR**) Constant value names (for example, **XmMENU\_OPTION**, **XmBROWSE\_SELECT**) Object types (for example, **XmPushButton**, **XmBulletinBoard**)

*Table 11. Unreserved Keywords*

| Item                  | Description   | Description       |
|-----------------------|---------------|-------------------|
| ANY                   | FILE          | IMPORTED          |
| ARGUMENT              | FLOAT         | REASON            |
| ASCIZ_STRING_TABLE    | FONT          | RGB               |
| ASCIZ_TABLE           | FONTSET       | SINGLE_FLOAT      |
| BACKGROUND            | FONT_TABLE    | STRING            |
| BOOLEAN               | FOREGROUND    | STRING_TABLE      |
| CASE_INSENSITIVE      | ICON          | TRANSLATION_TABLE |
| CASE_SENSITIVE        | INTEGER       | UNMANAGED         |
| CHARACTER_SET         | INTEGER_TABLE | USER_DEFINED      |
| COLOR                 | KEYSYM        | VERSION           |
| COLOR_TABLE           | MANAGED       | WIDE_CHARACTER    |
| COMPOUND_STRING       | NAMES         | WIDGET            |
| COMPOUND_STRING_TABLE | OBJECTS       | XBITMAPFILE       |
|                       | RIGHT_TO_LEFT |                   |

String literals can be composed of uppercase and lowercase letters, digits, and punctuation characters. Spaces, tabs, and comments are special elements in the language. They are a means of delimiting other elements, such as two names. One or more of these elements can be displayed before or after any other element in the language. However, spaces, tabs, and comments that are displayed in string literals are treated as character sequences rather than delimiters.

## Data Types

UIL provides literals for several of the value types it supports. Some of the value types are not supported as literals (for example, pixmaps and string tables). You can specify values for these types by using functions described in the "Functions" section. UIL directly supports the following literal types:

- String literal
- Integer literal
- Boolean literal
- Floating-point literal

UIL also includes the ANY data type, which is used to turn off compile-time checking of data types.

## String Literals

A string literal is a sequence of 0 or more 8-bit or 16-bit characters or a combination delimited by ' (single quotation marks) or " (double quotation marks). String literals can also contain multibyte characters delimited with double quotation marks. String literals can be no more than 2,000 characters long.

A single-quoted string literal can span multiple source lines. To continue a single-quoted string literal, end the continued line with a \ (backslash). The literal continues with the first character on the next line.

Double-quoted string literals cannot span multiple source lines. (Because double-quoted strings can contain escape sequences and other special characters, you cannot use the backslash character to designate the continuation of the string.) To build a string value that must span multiple source lines, use the concatenation operation that is described later in this section.

The syntax of a string literal can be one of the following:

```
'[CharacterString]'
[#CharSet]"[CharacterString]"
```

Both string forms associate a character set with a string value. UIL uses the following rules to determine the character set and storage format for string literals:

- A string declared as '*String*' is equivalent to #*CurCharSet*"*String*", where *CurCharSet* is the codeset portion of the value of the LANG environment variable. If the LANG environment variable is not set or has no code set component, *CurCharSet* is the value of XmFALLBACK\_CHARSET. By default, XmFALLBACK\_CHARSET is ISO8859-1 (equivalent to ISO\_LATIN1), but vendors can define a different default.
- A string declared as "*String*" is equivalent to #*CharSet*"*String*" if you specified *CharSet* as the default character set for the module. If no default character set has been specified for the module and either the -s option is provided to the uil command or the use\_setlocale\_flag value is set for the Uil function callable compiler, the string is interpreted to be a string in the current locale. This means that the string is parsed in the locale of the user by calling **setlocale** and its character set is set to a value of XmFONTLIST\_DEFAULT\_TAG. If the string is converted to a compound string, it is stored as a locale-encoded text segment. Otherwise, "*String*" is equivalent to #*CurCharSet*"*String*", where *CurCharSet* is interpreted as described for single-quoted strings.
- A string of the form "*String*" or #*CharSet*"*String*" is stored as a null-terminated string.

The following lists the character sets supported by the UIL compiler for string literals. Note that several UIL names map to the same character set. In some cases, the UIL name influences how string literals are read. For example, strings identified by a UIL character set name ending in \_LR are read left-to-right. Names that end in a different number reflect different fonts (for example, ISO\_LATIN1 or ISO\_LATIN6). All character sets in this list are represented by 8 bits.

| UIL Name      | Description                            |
|---------------|----------------------------------------|
| ISO_LATIN1    | GL: ASCII, GR: Latin-1 Supplement      |
| ISO_LATIN2    | GL: ASCII, GR: Latin-2 Supplement      |
| ISO_ARABIC    | GL: ASCII, GR: Latin-Arabic Supplement |
| ISO_LATIN6    | GL: ASCII, GR: Latin-Arabic Supplement |
| ISO_GREEK     | GL: ASCII, GR: Latin-Greek Supplement  |
| ISO_LATIN7    | GL: ASCII, GR: Latin-Greek Supplement  |
| ISO_HEBREW    | GL: ASCII, GR: Latin-Hebrew Supplement |
| ISO_LATIN8    | GL: ASCII, GR: Latin-Hebrew Supplement |
| ISO_HEBREW_LR | GL: ASCII, GR: Latin-Hebrew Supplement |
| ISO_LATIN8_LR | GL: ASCII, GR: Latin-Hebrew Supplement |
| JIS_KATAKANA  | GL: JIS Roman, GR: JIS Katakana        |

Following are the parsing rules for each of the character sets:

| <b>Character Set</b>                                                  | <b>Parsing Rule</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| All character sets                                                    | Character codes in the range 00 to 1F, 7F, and 80 to 9F are control characters including both bytes of 16-bit characters. The compiler flags these as illegal characters.                                                                                                                                                                                                                                                                                          |
| ISO_LATIN1, ISO_LATIN2, ISO_ARABIC, ISO_LATIN6, ISO_GREEK, ISO_LATIN7 | These sets are parsed from left to right. The escape sequences for null-terminated strings are also supported by these character sets.                                                                                                                                                                                                                                                                                                                             |
| ISO_HEBREW, ISO_LATIN8                                                | These sets are parsed from right to left. For example, the string #ISO_HEBREW"012345" generates a primitive string "543210" with the character set ISO_HEBREW. A DDIS descriptor for such a string has this segment marked as being right to left. The escape sequences for null-terminated strings are also supported by these character sets, and the characters that compose the escape sequences are in left-to-right order. For example, you type \n, not n\. |
| ISO_HEBREW_LR, ISO_LATIN8_LR                                          | These sets are parsed from left to right. For example, the string #ISO_HEBREW"012345" generates a primitive string "012345" with the character set ISO_HEBREW. A DDIS descriptor for such a string marks this segment as being left to right. The escape sequences for null-terminated strings are also supported by these character sets.                                                                                                                         |
| JIS_KATAKANA                                                          | This set is parsed from left to right. The escape sequences for null-terminated strings are also supported by these character sets. Note that the \ (backslash) can be displayed as a yen symbol.                                                                                                                                                                                                                                                                  |

In addition to designating parsing rules for strings, character set information remains an attribute of a compound string. If the string is included in a string consisting of several concatenated segments, the character set information is included with that string segment. This gives AIXwindows the information it needs to decipher the compound string and choose a font to display the string.

For an application interface displayed only in English, UIL lets you ignore the distinctions between the two uses of strings. The compiler recognizes by context when a string must be passed as a null-terminated string or as a compound string.

The UIL compiler recognizes enough information about the various character sets to correctly parse string literals. The compiler also issues errors if you use a compound string in a context that supports only null-terminated strings.

Since the character set names are keywords, you must put them in lowercase if case-sensitive names are in force. If names are case-insensitive, character set names can be uppercase, lowercase, or mixed case.

In addition to the built-in character sets recognized by UIL, you can define your own character sets with the **CHARACTER\_SET** function. You can use the **CHARACTER\_SET** function anywhere a character set can be specified.

String literals can contain characters with the eighth (high-order) bit set. You cannot type control characters (00 to 1F, 7F, and 80 to 9F) directly in a single-quoted string literal. However, you can represent these characters with escape sequences. The following list shows the escape sequences for special characters:

| Item      | Description                                                                                         |
|-----------|-----------------------------------------------------------------------------------------------------|
| \b        | Backspace                                                                                           |
| \f        | Form-feed                                                                                           |
| \n        | New-line                                                                                            |
| \r        | Carriage return                                                                                     |
| \t        | Horizontal tab                                                                                      |
| \v        | Vertical tab                                                                                        |
| \'        | Single quotation mark                                                                               |
| \"        | Double quotation mark                                                                               |
| \\\       | Backslash                                                                                           |
| \Integer\ | Character whose internal representation is given by <i>Integer</i> (in the range 0 to 255 decimal). |

**Note:** Escape sequences are processed literally in strings that are parsed in the current locale (localized strings).

The UIL compiler does not process new-line characters in compound strings. The effect of a new-line character in a compound string depends only on the character set of the string. The result is not guaranteed to be a multiline string.

### Compound String Literals

A compound string consists of a string of 8-bit, 16-bit, or multibyte characters, a named character set, and a writing direction. Its UIL data type is **compound\_string**.

The writing direction of a compound string is implied by the character set specified for the string. You can explicitly set the writing direction for a compound string by using the **COMPOUND\_STRING** function.

A compound string can consist of a sequence of concatenated compound strings, null-terminated strings, or a combination of both, each of which can have a different character set property and writing direction. Use the & (ampersand) concatenation operator to create a sequence of compound strings.

Each string in the sequence is stored, including the character set and writing direction information.

Generally, a string literal is stored in the UID file as a compound string when the literal consists of concatenated strings having different character sets or writing directions, or when you use the string to specify a value for an argument that requires a compound string value. If you want to guarantee that a string literal is stored as a compound string, you *must* use the **COMPOUND\_STRING** function.

### Data Storage Consumption for String Literals

The way a string literal is stored in the UID file depends on how you declare and use the string. The UIL compiler automatically converts a null-terminated string to a compound string if you use the string to specify the value of an argument that requires a compound string. However, this conversion is costly in terms of storage consumption.

**PRIVATE**, **EXPORTED**, and **IMPORTED** string literals require storage for a single allocation when the literal is declared; thereafter, storage is required for each reference to the literal. Literals declared in-line require storage for both an allocation and a reference.

The following list summarizes data storage consumption for string literals. The storage requirement for an allocation consists of a fixed portion and a variable portion. The fixed portion of an allocation is roughly the same as the storage requirement for a reference (a few bytes). The storage consumed by the variable portion depends on the size of the literal value (the length of the string). To conserve storage space, avoid making string literal declarations that result in an allocation per use.

| Declaration (and Data Type) | Used As         | Storage Requirements Per Use                      |
|-----------------------------|-----------------|---------------------------------------------------|
| In-line (Null-terminated)   | Null-terminated | An allocation and a reference (within the module) |
| Private (Null-terminated)   | Null-terminated | A reference (within the module)                   |
| Exported (Null-terminated)  | Null-terminated | A reference (within the UID hierarchy)            |
| Imported (Null-terminated)  | Null-terminated | A reference (within the UID hierarchy)            |
| In-line (Compound)          | Compound        | An allocation and a reference (within the module) |
| Private (Compound)          | Compound        | An allocation and a reference (within the module) |
| Exported (Compound)         | Compound        | A reference (within the UID hierarchy)            |
| Imported (Compound)         | Compound        | A reference (within the UID hierarchy)            |
| In-line (Compound)          | Compound        | An allocation and a reference (within the module) |
| Private (Compound)          | Compound        | A reference (within the module)                   |
| Exported (Compound)         | Compound        | A reference (within the UID hierarchy)            |
| Imported (Compound)         | Compound        | A reference (within the UID hierarchy)            |

## Integer Literals

An integer literal represents the value of a whole number. Integer literals have the form of an optional sign followed by one or more decimal digits. An integer literal must not contain embedded spaces or commas.

Integer literals are stored in the UID file as long integers. Exported and imported integer literals require a single allocation when the literal is declared; thereafter, a few bytes of storage are required for each reference to the literal. Private integer literals and those declared in-line require allocation and reference storage per use. To conserve storage space, avoid making integer literal declarations that result in an allocation per use.

The following list shows data storage consumption for integer literals:

| Declaration | Storage Requirements Per Use                       |
|-------------|----------------------------------------------------|
| In-line     | An allocation and a reference (within the module). |
| Private     | An allocation and a reference (within the module). |
| Exported    | A reference (within the UID hierarchy).            |
| Imported    | A reference (within the UID hierarchy).            |

## Boolean Literals

A Boolean literal represents the True value (reserved keyword **TRUE** or **On**) or False value (reserved keyword **FALSE** or **Off**). These keywords are subject to case-sensitivity rules.

In a UID file, **TRUE** is represented by the integer value 1 and **FALSE** is represented by the integer value 0.

Data storage consumption for Boolean literals is the same as that for integer literals.

## Floating-Point Literals

A floating-point literal represents the value of a real (or float) number. Floating-point literals have the following form:

**[+|-] [Integer].Integer[E|e[+|-]Exponent]**

For maximum portability, a floating-point literal can represent values in the range 1.0E-37 to 1.0E+37 with at least six significant digits. On many machines, this range is wider, with more significant digits. A floating-point literal must not contain embedded spaces or commas.

Floating-point literals are stored in the UID file as double-precision, floating-point numbers. The following gives examples of valid and invalid floating-point notation for the UIL compiler:

#### **Valid Floating-Point Literals**

1.0  
.1  
3.1415E-2 (equals .031415)  
-6.29e7 (equals -62900000)

#### **Invalid Floating-Point Literals**

1e1 (no decimal point)  
E-1 (no decimal point or digits)  
2.87 e6 (embedded blanks)  
2.0e100 (out of range)

Data storage consumption for floating-point literals is the same as that for integer literals.

### **ANY Data Type**

The purpose of the **ANY** data type is to shut off the data-type checking feature of the UIL compiler. You can use the **ANY** data type for either of the following:

- Specifying the type of a callback procedure tag.
- Specifying the type of a user-defined argument.

You can use the **ANY** data type when you need to use a type not supported by the UIL compiler or when you want the data-type restrictions imposed by the compiler to be relaxed. For example, you might want to define a widget having an argument that can accept different types of values, depending on run-time circumstances.

If you specify that an argument takes an **ANY** value, the compiler does not check the type of the value specified for that argument. Therefore, you need to take care when specifying a value for an argument of the **ANY** data type. You may get unexpected results at run time if you pass a value having a data type that the widget does not support for that argument.

### **Expressions**

UIL includes compile-time value expressions. These expressions can contain references to other UIL values, but cannot be forward-referenced.

The following lists the set of operators in UIL that allow you to create integer, real, and Boolean values based on other values defined with the UIL module. In the list, a precedence of 1 is the highest.

| <b>Operator (And Its Meaning)</b> | <b>Operand Types</b> | <b>Precedence</b> |
|-----------------------------------|----------------------|-------------------|
| <code>~ (NOT)</code>              | Boolean              | 1                 |
| <code>(Ones complement)</code>    | integer              |                   |
| <code>- (Negate)</code>           | float                | 1                 |
| <code>(Negate)</code>             | integer              |                   |
| <code>+ (NOP)</code>              | float                | 1                 |
| <code>(NOP)</code>                | integer              |                   |
| <code>* (Multiply)</code>         | float,float          | 2                 |
| <code>(Multiply)</code>           | integer,integer      |                   |
| <code>/ (Divide)</code>           | float,float          | 2                 |
| <code>(Divide)</code>             | integer,integer      |                   |
| <code>+ (Add)</code>              | float,float          | 3                 |
| <code>(Add)</code>                | integer,integer      |                   |

| Operator (And Its Meaning) | Operand Types   | Precedence |
|----------------------------|-----------------|------------|
| - (Subtract)               | float,float     | 3          |
| (Subtract)                 | integer,integer |            |
| >> (Shift right)           | integer,integer | 4          |
| << (Shift left)            | integer,integer | 4          |
| & (NOT)                    | Boolean,Boolean | 5          |
| (Bitwise AND)              | integer,integer |            |
| (Concatenate)              | string,string   |            |
| (OR)                       | Boolean,Boolean | 6          |
| (Bitwise OR)               | integer,integer |            |
| ^ (XOR)                    | Boolean,Boolean | 6          |
| (Bitwise XOR)              | integer,integer |            |

A string can be either a single compound string or a sequence of compound strings. If the two concatenated strings have different properties (such as writing direction or character set), the result of the concatenation is a multisegment compound string.

The string resulting from the concatenation is a null-terminated string unless one or more of the following conditions exists:

- One of the operands is a compound string.
- The operands have different character set properties.
- The operands have different writing directions.

If one or more of previous conditions are met, the resulting string is a compound string. You cannot use imported or exported values as operands of the concatenation operator.

The result of each operator has the same type as its operands. You cannot mix types in an expression without using conversion functions.

You can use parentheses to override the normal precedence of operators. In a sequence of unary operators, the operations are performed in right-to-left order. For example,  $- + -A$  is equivalent to  $-(+(-A))$ . In a sequence of binary operators of the same precedence, the operations are performed in left-to-right order. For example,  $A*B/C*D$  is equivalent to  $((A*B)/C)*D$ .

A value declaration gives a value a name. You cannot redefine the value of that name in a subsequent value declaration. You can use a value containing operators and functions anywhere you can use a value in a UIL module. You cannot use imported values as operands in expressions.

Several of the binary operators are defined for multiple data types. For example, the operator for multiplication (\*) is defined for both floating-point and integer operands.

For the UIL compiler to perform these binary operations, both operands must be of the same type. If you supply operands of different data types, the UIL compiler automatically converts one of the operands to the type of the other according to the following conversion rules:

- If the operands are an integer and a Boolean, the Boolean is converted to an integer.
- If the operands are an integer and a floating-point, the integer is converted to a floating-point.
- If the operands are a floating-point and a Boolean, the Boolean is converted to a floating-point.

You can also explicitly convert the data type of a value by using one of the **INTEGER**, **FLOAT**, or **SINGLE\_FLOAT** conversion functions.

## Functions

UIL provides functions to generate the following types of values:

- Character sets
- Keysyms
- Colors
- Pixmaps
- Single-precision, floating-point numbers
- Double-precision, floating-point numbers
- Fonts
- Font sets
- Font tables
- Compound strings
- Compound string tables
- ASCIZ (null-terminated) string tables
- Wide character strings
- Widget class names
- Integer tables
- Arguments
- Reasons
- Translation tables.

All examples in the following sections assume case-insensitive mode. Keywords are shown in uppercase letters to distinguish them from user-specified names, which are shown in mixed-case italics. This use of uppercase letters is not required in case-insensitive mode. In case-sensitive mode, keywords must be in lowercase letters.

### **CHARACTER\_SET(*StringExpression*[,*Property*[,...]])**

You can define your own character sets with the **CHARACTER\_SET** function. You can use the **CHARACTER\_SET** function anywhere a character set can be specified.

The result of the **CHARACTER\_SET** function is a character set with the name *StringExpression* and the properties you specify. *StringExpression* must be a null-terminated string. You can optionally include one or both of the following clauses to specify properties for the resulting character set: **RIGHT\_TO\_LEFT** = *BooleanExpression* **SIXTEEN\_BIT** = *BooleanExpression*

The **RIGHT\_TO\_LEFT** clause sets the default writing direction of the string from right to left if *BooleanExpression* is True, and left to right otherwise.

The **SIXTEEN\_BIT** clause allows the strings associated with this character set to be interpreted as 16-bit characters if *BooleanExpression* is True, and 8-bit characters otherwise.

### **KEYSYM(*StringLiteral*)**

The **KEYSYM** function is used to specify a keysym for a mnemonic resource. The *StringLiteral* must contain exactly one character. If the **-s** compiler flag is used, *StringLiteral* which uses double quotes must specify a character set.

### **COLOR(*StringExpression*[, **FOREGROUND** | **BACKGROUND**])**

The **COLOR** function supports the definition of colors. Using the **COLOR** function, you can designate a value to specify a color and use that value for arguments requiring a color value. The string expression names the color you want to define. The optional **FOREGROUND** and **BACKGROUND** keywords identify how the color is to be displayed on a monochrome device when the color is used in the definition of a color table.

The UIL compiler does not have built-in color names. Colors are a server-dependent attribute of an object. Colors are defined on each server and may have different red-green-blue (RGB) values on each server. The string you specify as the color argument must be recognized by the server on which your application runs.

In a UID file, UIL represents a color as a character string. MRM calls X translation functions that convert a color string to the device-specific pixel value. If you are running on a monochrome server, all colors translate to black or white. If you are on a color server, the color names translate to their proper colors if the following conditions are met:

- The color is defined.
- The color map is not yet full.

If the color map is full, even valid colors translate to black or white (foreground or background).

Generally, interfaces do not specify colors for widgets. This enables the selection of colors to be controlled by the user through the **.Xdefaults** file.

To write an application that runs on both monochrome and color devices, you need to specify which colors in a color table (defined with the **COLOR\_TABLE** function) map to the background and which colors map to the foreground. UIL lets you use the **COLOR** function to map the color red to the background color on a monochrome device as follows:

```
VALUE c: COLOR ('red',BACKGROUND);
```

Mapping is necessary only when the MRM is given a color and the application is to be displayed on a monochrome device. In this case, each color is considered to be in one of the following three categories:

- The color is mapped to the background color on the monochrome device.
- The color is mapped to the foreground color on the monochrome device.
- Monochrome mapping is undefined for this color.

If the color is mapped to the foreground or background color, MRM substitutes the foreground or background color, respectively. If you do not specify the monochrome mapping for a color, MRM passes the color string to AIXwindows for mapping to the foreground or background color.

#### **RGB**(*RedInteger*, *GreenInteger*, *BlueInteger*)

The three integers define the values for the red, green, and blue components of the color, in that order. The values of these components can range from 0 to 65,535, inclusive.

In a UID file, UIL represents an RGB value as three integers. MRM calls X translation functions that convert the integers to the device-specific pixel value. If you are running on a monochrome server, all colors translate to black or white. If you are on a color server, RGB values translate to their proper colors if the color map is not yet full. If the color map is full, values translate to black or white (foreground or background).

#### **COLOR\_TABLE**(*ColorExpression*='Character'[, ...])

The color expression is a previously defined color, a color defined in-line with the **COLOR** function, or the phrase **BACKGROUND COLOR** or **FOREGROUND COLOR**. The character can be any valid UIL character.

The **COLOR\_TABLE** function provides a device-independent way to specify a set of colors. The **COLOR\_TABLE** function accepts either previously defined UIL color names or in-line color definitions (using the **COLOR** function). A color table must be private because its contents must be known by the UIL compiler to construct an icon. The colors within a color table, however, can be imported, exported, or private.

The single letter associated with each color is the character you use to represent that color when creating an icon. Each letter used to represent a color must be unique within the color table.

## **ICON([COLOR\_TABLE=ColorTableName,] Row[, ...])**

The color table name must refer to a previously defined color table. The row is a character expression that gives one row of the icon.

The **ICON** function describes a rectangular icon that is  $x$  pixels wide and  $y$  pixels high. The strings surrounded by single quotation marks describe the icon. Each string represents a row in the icon; each character in the string represents a pixel.

The first row in an icon definition determines the width of the icon. All rows must have the same number of characters as the first row. The height of the icon is dictated by the number of rows.

The first argument of the **ICON** function (the color table specification) is optional and identifies the colors that are available in this icon. By using the single letter associated with each color, you can specify the color of each pixel in the icon. The icon must be constructed of characters defined in the specified color table.

A default color table is used if you omit the argument specifying the color table. To make use of the default color table, the rows of your icon must contain only spaces and asterisks. The default color table is defined as follows:

```
COLOR_TABLE(BACKGROUND COLOR = ' ', FOREGROUND COLOR = '*')
```

You can define other characters to represent the background color and foreground color by replacing the space and asterisk in the **BACKGROUND COLOR** and **FOREGROUND COLOR** clauses shown in the example statement. You can specify icons as private, imported, or exported. Use the **MrmFetchIconLiteral** MRM function to retrieve an exported icon at run time.

## **XBITMAPFILE(StringExpression)**

The **XBITMAPFILE** function is similar to the **ICON** function in that both describe a rectangular icon that is  $x$  pixels wide and  $y$  pixels high. However, the **XBITMAPFILE** function allows you to specify an external file containing the definition of an X bitmap, while all **ICON** function definitions must be coded directly within UIL. X bitmap files can be generated by many different X applications. UIL reads these files through the **XBITMAPFILE** function, but does not support creation of these files. The X bitmap file specified as the argument to the **XBITMAPFILE** function is read by MRM at application run time.

The **XBITMAPFILE** function returns a value of type pixmap and can be used anywhere a pixmap data type is expected.

## **SINGLE\_FLOAT(RealNumberLiteral)**

The **SINGLE\_FLOAT** function lets you store floating-point literals in UIL files as single-precision, floating-point numbers. Single-precision, floating-point numbers can often be stored using less memory than double-precision, floating-point numbers. The *RealNumberLiteral* can be either an integer literal or a floating-point literal. A value defined using this function cannot be used in an arithmetic expression.

## **FLOAT(RealNumberLiteral)**

The **FLOAT** function lets you store floating-point literals in UIL files as double-precision, floating-point numbers. The *RealNumberLiteral* can be either an integer literal or a floating-point literal.

## **FONT(StringExpression[,CHARACTER\_SET=CharSet])**

You define fonts with the **FONT** function. Using the **FONT** function, you designate a value to specify a font and use that value for arguments that require a font value. The UIL compiler has no built-in fonts.

Each font makes sense only in the context of a character set. The **FONT** function has an additional parameter to let you specify the character set for the font. This parameter is optional; if you omit it, the default character set depends on the value of the **LANG** environment variable. If **LANG** is not set, the default character set is set to **XmFALLBACK\_CHARSET**.

The string expression specifies the name of the font and the clause **CHARACTER\_SET=CharSet** specifies the character set for the font. The string expression used in the **FONT** function cannot be a compound string.

#### **FONTSET**(*StringExpression[,...][,CHARACTER\_SET=CharSet]*)

You define fontsets with the **FONTSET** function. Using the **FONTSET** function, you designate a set of values to specify a font and use those values for arguments that require a fontset value. The UIL compiler has no built-in fonts.

Each font makes sense only in the context of a character set. The **FONTSET** function has an additional parameter to let you specify the character set for the font. This parameter is optional; if you omit it, the default character set depends on the value of the **LANG** environment variable. If **LANG** is not set, the default character set is set to **XmFALLBACK\_CHARSET**.

The string expression specifies the name of the font and the clause **CHARACTER\_SET=CharSet** specifies the character set for the font. The string expression used in the **FONTSET** function cannot be a compound string.

#### **FONT\_TABLE**(*FontExpression[,...]*)

A font table is a sequence of pairs of fonts and character sets. At run time when an object needs to display a string, the object scans the font table for the character set that matches the character set of the string to be displayed. UIL provides the **FONT\_TABLE** function to let you supply such an argument. The font expression is created with the **FONT** and **FONTSET** functions.

If you specify a single font value to specify an argument that requires a font table, the UIL compiler automatically converts a font value to a font table.

#### **COMPOUND\_STRING**(*StringExpression[Property[,...]]*)

Use the **COMPOUND\_STRING** function to set properties of a null-terminated string and to convert it into a compound string. The properties you can set are the character set, writing direction, and separator.

The result of the **COMPOUND\_STRING** function is a compound string with the string expression as its value. You can optionally include one or more of the following clauses to specify properties for the resulting compound string:

**CHARACTER\_SET=CharacterSet** **RIGHT\_TO\_LEFT=BooleanExpression**  
**SEPARATE=BooleanExpression**

The **CHARACTER\_SET** clause specifies the character set for the string. If you omit the **CHARACTER\_SET** clause, the resulting string has the same character set as *StringExpression*.

The **RIGHT\_TO\_LEFT** clause sets the writing direction of the string from right to left if *BooleanExpression* is True. Otherwise, writing direction is left to right. Specifying this argument does not cause the value of the string expression to change. If you omit the **RIGHT\_TO\_LEFT** argument, the resulting string has the same writing direction as *StringExpression*.

The **SEPARATE** clause appends a separator to the end of the compound string if *BooleanExpression* is True. If you omit the **SEPARATE** clause, the resulting string does not have a separator.

You cannot use imported or exported values as the operands of the **COMPOUND\_STRING** function.

#### **COMPOUND\_STRING\_TABLE**(*StringExpression[,...]*)

A compound string table is an array of compound strings. Objects requiring a list of string values, such as the **XmNitems** and **XmNselectedItems** arguments for the **List** widget, use string table values. The **COMPOUND\_STRING\_TABLE** function builds the values for these two arguments of the **List** widget. The **COMPOUND\_STRING\_TABLE** function generates a value of type **string\_table**. The name **STRING\_TABLE** is a synonym for **COMPOUND\_STRING\_TABLE**.

The strings inside the string table can be simple strings, which the UIL compiler automatically converts to compound strings.

**ASCIZ\_STRING\_TABLE(*StringExpression*[,...])**

An ASCIZ string table is an array of ASCIZ (null-terminated) string values separated by commas. This function allows you to pass more than one ASCIZ string as a callback tag value. The **ASCIZ\_STRING\_TABLE** function generates a value of type **asciz\_table**. The name **ASCIZ\_TABLE** is a synonym for **ASCIZ\_STRING\_TABLE**.

**WIDE\_CHARACTER(*StringExpression*)**

Use the **WIDE\_CHARACTER** function to generate a wide character string from a null-terminated string in the current locale.

**CLASS\_REC\_NAME(*StringExpression*)**

Use the **CLASS\_REC\_NAME** function to generate a widget class name. For a widget class defined by the toolkit, the string argument is the name of the class. For a user-defined widget, the string argument is the name of the creation function for the widget.

**INTEGER\_TABLE(*IntegerExpression*[,...])**

An integer table is an array of integer values separated by commas. This function allows you to pass more than one integer per callback tag value. The **INTEGER\_TABLE** function generates a value of type **integer\_table**.

**ARGUMENTS(*StringExpression*[,*ArgumentType*])**

The **ARGUMENTS** function defines the arguments to a user-defined widget. Each of the objects that can be described by UIL permits a set of arguments. For example, **XmNheight** is an argument to most objects and has the integer data type. To specify height for a user-defined widget, you can use the built-in argument name **XmNheight** and specify an integer value when you declare the user-defined widget. Do not use the **ARGUMENTS** function to specify arguments that are built into the UIL compiler.

The *StringExpression* name is the name the UIL compiler uses for the argument in the UID file. The *ArgumentType* is the type of value that can be associated with the argument. If you omit the second argument, the default type is ANY and no value type checking occurs. Use any of the following keywords to specify the argument type:

- **Any**
- **Asciz\_Table**
- **Boolean**
- **Color**
- **Color\_Table**
- **Compound\_String**
- **Float**
- **Font**
- **Font\_Table**
- **Fontset**
- **Icon**
- **Integer**
- **Integer\_Table**
- **Reason**
- **Single\_Float**
- **String**
- **String\_Table**
- **Translation\_Table**
- **Wide\_Character**
- **Widget**

You can use the **ARGUMENTS** function to allow the UIL compiler to recognize extensions to AIXwindows. For example, an existing widget can accept a new argument. Using the **ARGUMENTS** function, you can make this new argument available to the UIL compiler before the updated version of the compiler is released.

#### **REASON**(*StringExpression*)

The **REASON** function is useful for defining new reasons for user-defined widgets.

Each of the objects in AIXwindows defines a set of conditions under which it calls a user-defined function. These conditions are known as *callback reasons*. The user-defined functions are called *callback procedures*. In a UIL module, you use a callbacks list to specify which user-defined functions are to be called for which reasons.

When you declare a user-defined widget, you can define callback reasons for that widget using the **REASON** function. The string expression specifies the argument name stored in the UID file for the reason. This reason name is supplied to the widget creation function at run time.

#### **TRANSLATION\_TABLE**(*StringExpression[,...]*)

Each of the AIXwindows widgets have a translation table that maps X events (for example, pressing mouse button 1) to a sequence of actions. Through widget arguments, such as the common translations argument, you can specify an alternate set of events or actions for a particular widget. The **TRANSLATION\_TABLE** function creates a translation table that can be used as the value of an argument that is of the data type `translation_table`.

You can use one of the following translation table directives with the **TRANSLATION\_TABLE** function: **#override**, **#augment**, or **#replace**. The default is **#replace**. If you specify one of these directives, it must be the first entry in the translation table.

The **#override** directive causes any duplicate translations to be ignored. For example, if a translation for `<Btn1Down>` is already defined in the current translations for a PushButton, the translation defined by *NewTranslations* overrides the current definition. If the **#augment** directive is specified, the current definition takes precedence. The **#replace** directive replaces all current translations with those specified in the **XmNtranslations** resource.

## **utmp, wtmp, failedlogin File Format**

### Purpose

Describes formats for user and accounting information.

### Description

The **utmp** file, the **wtmp** file, and the **failedlogin** file contain records with user and accounting information.

When a user attempts to logs in, the **login** program writes entries in two files:

- The **/etc/utmp** file, which contains a record of users logged into the system.
- The **/var/adm/wtmp** file (if it exists), which contains connect-time accounting records.

On an invalid login attempt, due to an incorrect login name or password, the **login** program makes an entry in:

- The **/etc/security/failedlogin** file, which contains a record of unsuccessful login attempts.

The records in these files follow the **utmp** format, defined in the **utmp.h** header file.

## Files

| Item                             | Description                                        |
|----------------------------------|----------------------------------------------------|
| <b>/etc/utmp</b>                 | Contains a record of users logged into the system. |
| <b>/var/adm/wtmp</b>             | Contains connect accounting information.           |
| <b>/etc/security/failedlogin</b> | Contains a record of invalid login attempts.       |

## vgrindefs File Format

### Purpose

Contains the language definition database for the **vgrind** command.

### Description

The **vgrindefs** file format contains all the language definitions for the **vgrind** command. The database is very similar to the **terminfo** file format (file of terminal capabilities).

### Fields

The following table contains the name and description of each field:

| Name | Type | Description                                                          |
|------|------|----------------------------------------------------------------------|
| ab   | str  | Alternate regular expression for the start of a comment.             |
| ae   | str  | Alternate regular expression for the end of a comment.               |
| pb   | str  | Regular expression for the start of a procedure.                     |
| bb   | str  | Regular expression for the start of a lexical block.                 |
| be   | str  | Regular expression for the end of a lexical block.                   |
| cb   | str  | Regular expression for the start of a comment.                       |
| ce   | str  | Regular expression for the end of a comment.                         |
| sb   | str  | Regular expression for the start of a string.                        |
| se   | str  | Regular expression for the end of a string.                          |
| lb   | str  | Regular expression for the start of a character constant.            |
| le   | str  | Regular expression for the end of a character constant.              |
| tl   | bool | Presence means procedures are only defined at the top lexical level. |
| oc   | bool | Presence means upper and lowercase are equivalent.                   |

| Name | Type | Description                           |
|------|------|---------------------------------------|
| kw   | str  | List of keywords separated by spaces. |

## Examples

The following entry, which describes the C language, is typical of a language entry:

```
C|c: :pb=^d?*?\d?\p\d???:bb={:be=}:cb=/*:ce=*:sb=:se=\e:\:
:lb=:le=\e':tl:\
:kw=asm auto break case char continue default do
 double else enum\
extern float for fortran goto if int long register
 return short\
sizeof static struct switch typedef union unsigned
 while #define\
#else #endif #if #ifdef #ifndef #include #undef # define
 else endif\
 if ifdef ifndef include undef:
```

The first field is the language name or any variants of the name. Thus the C language can be specified to the **vgrind** command in either lowercase or uppercase c.

Entries can continue onto multiple lines by giving a \ (backslash) as the last character of a line. The **vgrindefs** file format has the following two capabilities:

- Boolean capabilities that indicate a particular feature of the language
- String capabilities that give a regular expression or keyword list.

In the Java™ language, where comments can be delimited either by a starting "/" or an ending "\*", or by a starting "//" and "end" at the end of the line, the Java **vgrindefs** definition might be:

```
cb=/*:ce=*:ab//:ae=$
```

## Regular Expressions

The **vgrindefs** file format uses regular expressions similar to those of the **ex** command and the **lex** command. The characters ^ (caret), \$ (dollar sign), : (colon), and \ (backslash) are reserved characters and must be quoted with a preceding \ (backslash) if they are to be included as normal characters. The metasymbols and their meanings follow:

| Item | Description                                                                                                                                                                                                                                       |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \$   | End of a line.                                                                                                                                                                                                                                    |
| ^    | Beginning of a line.                                                                                                                                                                                                                              |
| \d   | Delimiter (space, tab, newline, start of line).                                                                                                                                                                                                   |
| \a   | Matches any string of symbols, such as .* in the <b>lex</b> command.                                                                                                                                                                              |
| \p   | Matches any alphanumeric name. In a procedure definition (pb), the string that matches this symbol is used as the procedure name.                                                                                                                 |
| ( )  | Grouping.                                                                                                                                                                                                                                         |
|      | Alternation.                                                                                                                                                                                                                                      |
| ?    | Last item is optional.                                                                                                                                                                                                                            |
| \e   | Preceding any string, means that the string does not match an input string if the input string is preceded by an escape character (\). Typically used for languages (such as C) that can include the string delimiter in a string by escaping it. |

Unlike other regular expressions in the system, these metasymbols match words and not characters. Hence the pattern "(tramp|steamer)flies?" matches "tramp," "steamer," "trampflies," or "steamerflies."

## Keyword List

The keyword list lists keywords in the language, separated by spaces. If the oc field is specified, indicating that uppercase and lowercase are equivalent, then all the keywords should be specified in lowercase.

## Files

| Item                     | Description                     |
|--------------------------|---------------------------------|
| /usr/share/lib/vgrindefs | Contains terminal descriptions. |

## WML File Format

### Purpose

Generates variable UIL compiler components.

### Description

The widget meta-language facility (WML) is used to generate changeable components of the user interface language (UIL) compiler, depending on the widget set. Using WML, you can add new widget UIL support to the AIXwindows widget set or add support for a totally new widget set.

### File Format

WML files are ASCII files and can be modified with any standard text editor. They are accessed by WML in the **tools/wml** directory and have a **.wml** suffix. The Motif AIXwindows widget set is described in the **motif.wml** file. This is also the default WML file when using the WML facility.

When creating a WML file to add new widgets or change widget characteristics, you can make a copy of the **motif.wml** file and modify it. If you are creating a new widget set for use with UIL, create a completely new file. In either case, the **motif.wml** file is a good example of WML syntax and can help familiarize you with the language before attempting to write your own WML file.

WML files have a basic syntax that is similar in structure to UIL. WML syntax is made up of the following elements:

- Comments
- Data Type Definitions
- Character Set Definitions
- Enumeration Set Definitions
- Control List Definitions
- Class Definitions
- Child Definitions
- Resource Definitions

You can use spaces, tabs, or new-line characters anywhere in syntax, as long as they do not split keywords or strings. Comments end at a new-line character. The order of elements in syntax is not important.

The widget meta-language syntax examples shown use the following additional conventions:

| Item | Description                                           |
|------|-------------------------------------------------------|
| [ ]  | Indicates optional elements.                          |
| ...  | Indicates where an element of syntax can be repeated. |
|      | Indicates a choice among multiple items.              |

## Comments

You can include comments in the WML file. Comments have the following syntax:

*[AnyElement]!AnyComment*

Comments begin with an ! (exclamation point) and extend to the end of the line. A comment can begin on a line by itself or follow any part of another element. A comment does not change the meaning of any other element. For example:

```
!This is a comment
! that spans two lines.
DataType !This is a comment that follows code.
```

## Data Type Definitions

*Data type definitions* register all the resource data types used in the file. You must register all the data types used in your WML file. Data type definitions have the following syntax:

**DataType** *AnyDatatype* [{ **InternalLiteral** = *InternalName* | **DocName** = "String"; [...] }]; [...]

A data type definition begins with the **DataType** keyword. Following the **DataType** keyword is a list of data types that can be modified with the following:

| Item                   | Description                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>InternalLiteral</b> | Forces the value of the internal symbol table literal definition of the data type name. This modifier is used only to circumvent symbol table definitions hard-coded into the UIL compiler and should be used sparingly. |
| <b>DocName</b>         | Gives an arbitrary string for use in the documentation. This string supplies a different name for the data type or a single name for the data type if the data type has aliases.                                         |

For example:

```
DataType OddNumber {DocName="OddNumber";}
NewString;
```

## Character Set Definitions

*Character set definitions* register the AIXwindows Toolkit name and other information for the character set names used in UIL. Character set definitions have the following syntax:

**CharacterSet** *AnyCharacterSet* { [ **FontListElementTag** | **XmStringCharsetName** ] = "String"; [ **Alias** = "String" ... ; | **Direction** = [ **LeftToRight** | **RightToLeft** ] ; | **ParseDirection** = [ **LeftToRight** | **RightToLeft** ] ; | **CharacterSize** = [ **OneByte** | **TwoByte** ] ; ] [ ... ] } ; [ ... ]

A character set definition begins with the **CharacterSet** keyword. Following the **CharacterSet** keyword is a list of character sets that can be modified with the following:

| Item                                            | Description                                                                                                                                                                                            |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>FontListElementTag   XmStringCharsetName</b> | Specifies the name of the character set. The set specified becomes the character set component of the compound string segment that is created. One of these character sets must be specified.          |
| <b>Alias</b>                                    | Specifies one or more aliases for the character set name. Each alias can be used within UIL to refer to the same character set.                                                                        |
| <b>Direction</b>                                | Specifies the direction of a compound string segment created using this character set. The default is <b>LeftToRight</b> .                                                                             |
| <b>ParseDirection</b>                           | Specifies the direction in which an input string is parsed when a compound string segment is created using this character set. If this is not specified, the value of <b>Direction</b> is the default. |
| <b>CharacterSize</b>                            | Specifies the number of bytes in each character of a compound string segment created using this character set. The default is <b>OneByte</b> .                                                         |

An example of the character set definition syntax is as follows:

```
CharacterSet
iso_latin1
 { XmStringCharsetName = "ISO8859-1";
 Alias = "ISOLatin1"; } ;
iso_hebrew_lr
 { XmStringCharsetName = "ISO8859-8";
 Alias = "iso_latin8_lr";
 Direction = RightToLeft;
 ParseDirection = LeftToRight; } ;
ksc_korean
 { XmStringCharsetName = "KSC5601.1987-0";
 CharacterSize = TwoByte; };
```

### Enumeration Set Definitions

*Enumeration set definitions* register the named constants used in the AIXwindows Toolkit to specify certain resource values. Enumeration set definitions have the following syntax:

```
EnumerationSet resourceName : ResourceType { EnumerationValueName ; [...] } ;
```

An enumeration set definition begins with the **EnumerationSet** keyword. For each enumeration set defined, the name and type of the resource is listed. The resource name is the AIXwindows Toolkit resource name, with the beginning **XmN** prefix removed and the initial letter capitalized. For example, the name of the AIXwindows Toolkit resource **XmNrowColumnType** would be **RowColumnType**. The resource type is the data type for the resource; for most resources, this is the integer data type. Following the resource name and type is a list of enumeration value names that can be used as settings for the resource. These names are the same as those in the AIXwindows Toolkit.

An example of the enumeration set definition syntax is as follows:

```
EnumerationSet
RowColumnType: integer
{ XmWORK_AREA; XmMENU_BAR; XmMENU_POPUP;
 XmMENU_PULLDOWN; XmMENU_OPTION; };
```

### Control List Definitions

*Control list definitions* assign a name to groups of controls. You can use these control lists later in class definitions to simplify the structure of your WML file. Control list definitions have the following syntax:

```
ControlList AnyControlList [{ AnyControl; [...] }];
```

A control list definition starts with the **ControlList** keyword. Following the **ControlList** keyword are any number of control list definitions. Control list definitions are made up of a control list name followed by the set of controls it represents. For example:

```
ControlList
 Buttons {PushButton;
 RadioButton;
 CascadeButton;
 NewCascadebutton; } ;
```

Each control specified in the control list must be defined as a class in the file.

## Class Definitions

*Class definitions* describe a particular widget class. Included in this description is its position in the class hierarchy, toolkit convenience function, resources, and controls. There should be one class definition for each widget or gadget in the widget set you want to support in UIL. Class definitions have the following syntax:

```
Class ClassName : MetaClass | Widget | Gadget {[
 SuperClass = ClassName; | ParentClass =
 ParentClassName; | InternalLiteral = InternalName; | Alias = Alias; | ConvenienceFunction =
 ConvenienceFunction; | WidgetClass = WidgetClass ; | DocName = "String"; | DialogClass = True | False;
 | Resources { AnyResourceName [{ Default = NewDefaultValue; | Exclude = True | False; [...] }]; [...] }; |
 Controls { AnyControlName; [...] }; Children { AnyChildName; [...] }; [...]]};
```

Class definitions start with the **Class** keyword. For each class defined, the name of the class and whether the class is a metaclass, widget, or gadget is listed. Each class definition can be modified using the following:

| Item                       | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SuperClass</b>          | Indicates the name of the parent class. Only the root of the hierarchy does not specify a super class.                                                                                                                                                                                                                                                                                        |
| <b>ParentClass</b>         | Indicates the name of the widget's automatically created parent class, if one exists. This allows resources for the automatically created parent class to be used in this class definition. For example, <b>XmBulletinBoardDialog</b> creates both an <b>XmBulletinBoard</b> and an <b>XmDialogShell</b> . To access the resources of the <b>XmDialogShell</b> parent class, specify it here. |
| <b>InternalLiteral</b>     | Forces the value of the internal symbol table literal definition of the class name. This modifier is used only to circumvent symbol table definitions hard-coded into the UIL compiler and should be used sparingly.                                                                                                                                                                          |
| <b>Alias</b>               | Indicates alternate class names for use in a UIL specification.                                                                                                                                                                                                                                                                                                                               |
| <b>ConvenienceFunction</b> | Indicates the name of the creation convenience function for this class. All widget and gadget classes must have <b>ConvenienceFunction</b> specified.                                                                                                                                                                                                                                         |
| <b>WidgetClass</b>         | Indicates the associated widget class of gadget type classes. This value is currently not recognized.                                                                                                                                                                                                                                                                                         |
| <b>DocName</b>             | Defines an arbitrary string for use in the documentation. This value is currently not recognized.                                                                                                                                                                                                                                                                                             |
| <b>DialogClass</b>         | Indicates whether the class is a dialog class. This value is currently not recognized.                                                                                                                                                                                                                                                                                                        |
| <b>Resources</b>           | Lists the resources of the widget class. This keyword can be further modified with the following:                                                                                                                                                                                                                                                                                             |
| <b>Default</b>             | Specifies a new default value for this resource. Resource default values are usually set in the resource definition. If an inherited resource's default value is changed by the class, the new default value should be noted here.                                                                                                                                                            |
| <b>Exclude</b>             | Specifies whether an inherited resource should be excluded from the resource list of the class. The default value is False.                                                                                                                                                                                                                                                                   |

| Item            | Description                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Children</b> | Lists the names of the automatically created children of this class. This allows those children to be accessed in the UIL file.        |
| <b>Controls</b> | Lists the controls that the widget class allows. The controls can be other classes or a control list from the control definition list. |

An example of the usage of the preceding data type and control list definitions is shown:

```

Class
 TopLevelWidget : MetaClass
 {
 Resources
 {
 XtbNfirstResource;
 XtbNsecondResource;
 };
 };

 NewWidget : Widget
 {
 SuperClass = TopLevelWidget;
 ConvenienceFunction =
 XtbCreateNewWidget;
 Resources
 {
 XtbNnewResource;
 XtbNfirstResource
 {Default="XtbNEW_VALUE";};
 XtbNsecondResource
 {Exclude=True;};
 };
 Controls
 {
 NewWidget;
 Buttons;
 };
 };
}

```

## Child Definitions

Child definitions register the classes of automatically created children. Automatically created children are referenced elsewhere in a UIL file using the **Children** keyword within a class definition. Child definitions have the following syntax:

**Child** *ChildName* : *ClassName*; [...]

*ChildName* is the name of the automatically created child and *ClassName* is the name of the class of that child.

## Resource Definitions

Resource definitions describe a particular resource. Included in this description is its type and default value. Each new resource reference in a class definition should have a resource definition. Resource definitions have the following syntax:

**Resource** *ResourceName* : **Argument** | **Reason** | **Constraint** | **SubResource** [[**Type** = *Type* ; | **ResourceLiteral** = *ResourceLiteral* ; | **InternalLiteral** = *InternalName* ; | **Alias** = *Alias* ; | **Related** = *Related* ; | **Default** = *Default* ; | **DocName** = *DocumentName* ; | [...]]] [...]

Resource definitions start with the **Resource** keyword. For each resource definition, the name of the resource and whether the resource is an argument, reason, constraint, or subresource is listed.

| Item               | Description                             |
|--------------------|-----------------------------------------|
| <b>Argument</b>    | Indicates a standard resource.          |
| <b>Reason</b>      | Indicates a callback resource.          |
| <b>Constraint</b>  | Indicates a constraint resource.        |
| <b>SubResource</b> | This value is currently not recognized. |

A resource definition can be modified with the following:

| Item                   | Description                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Type</b>            | Indicates the data type of the resource. The data type specified must be listed in the data type definition.                                                                                                                                                          |
| <b>ResourceLiteral</b> | Indicates the keyword used in the UIL file to reference the resource. In AIXwindows, the resource name is the same as the resource literal name ( <b>ResourceLiteral</b> ).                                                                                           |
| <b>InternalLiteral</b> | Forces the value of the internal symbol table literal definition of the resource name. This modifier is used only to circumvent symbol table definitions hard-coded into the UIL compiler and should be used sparingly.                                               |
| <b>Alias</b>           | Indicates alternate names for the resources used in a UIL specification.                                                                                                                                                                                              |
| <b>Related</b>         | Special purpose field that allows resources that act as a counter for the current resources to be related to the resource. UIL automatically sets the value of this related resource to the number of items in the compiled instance of the <i>ResourceName</i> type. |
| <b>Default</b>         | Indicates the default value of the resource.                                                                                                                                                                                                                          |
| <b>DocName</b>         | Defines an arbitrary string for use in the documentation. This value is currently not recognized.                                                                                                                                                                     |

An example of the usage of data type, control list, and class definitions is shown:

```
Resource
 XtbNfirstResource : Argument
 { Type = OddNumber;
 Default = "XtbOLD_VALUE";};
 XtbNsecondResource : Argument
 { Type = NewString;
 Default = "XtbNEW_STRING";};
 XtbNnewResource : Argument
 { Type = OddNumber;
 Default = "XtbODD_NUMBER";};
```

## XCOFF Object File Format

### Purpose

The extended common object file format (XCOFF) is the object file format for the operating system. XCOFF combines the standard common object file format (COFF) with the TOC module format concept, which provides for dynamic linking and replacement of units within an object file. A variation of XCOFF is used for 64-bit object files and executable files.

XCOFF is the formal definition of machine-image object and executable files. These object files are produced by language processors (assemblers and compilers) and the binder (or link editor), and are used primarily by the binder and the system loader.

The default name for an XCOFF executable file is **a.out**.

**Note:** This information lists bits in big-endian order.

Read the following information to learn more about XCOFF object files:

- Composite File Header
- Sections and Section Headers

- Relocation Information for XCOFF File (reloc.h)
- Line Number Information for XCOFF File (linenum.h)
- Symbol Table Information
- dbx Stabstrings

## Writing Applications that Use XCOFF Declarations

Programs can be written to understand 32-bit XCOFF files, 64-bit XCOFF files, or both. The programs themselves may be compiled in 32-bit mode or 64-bit mode to create 32-bit or 64-bit programs. By defining preprocessor macros, applications can select the proper structure definitions from the XCOFF header files.

**Note:** This document uses "XCOFF32" and "XCOFF64" as shorthand for "32-bit XCOFF" and "64-bit XCOFF", respectively.

### Selecting XCOFF32 Declarations

To select the XCOFF32 definitions, an application merely needs to include the appropriate header files. Only XCOFF32 structures, fields, and preprocessor defines will be included.

### Selecting XCOFF64 Declarations

To select the XCOFF64 definitions, an application should define the preprocessor macro `_XCOFF64_`. When XCOFF header files are included, the structures, fields, and preprocessor defines for XCOFF64 will be included. Where possible, the structure names and field names are identical to the XCOFF32 names, but field sizes and offsets may differ.

### Selecting Both XCOFF32 and XCOFF64 Declarations

To select structure definitions for both XCOFF32 and XCOFF64, an application should define both the preprocessor macros `_XCOFF32_` and `_XCOFF64_`. This will define structures for both kinds of XCOFF files. Structures and typedef names for XCOFF64 files will have the suffix `_64` added to them. (Consult the header files for details.)

### Selecting Hybrid XCOFF Declarations

An application may choose to select single structures that contain field definitions for both XCOFF32 and XCOFF64 files. For fields that have the same size and offset in both XCOFF32 and XCOFF64 definitions, the field names are retained. For fields whose size or offset differ between XCOFF32 and XCOFF64 definitions, the XCOFF32 fields have a "32" suffix, while the XCOFF64 fields have a "64" suffix. To select hybrid structure definitions, an application should define the preprocessor macro `_XCOFF_HYBRID_`. For example, the symbol table definition (in `/usr/include/syms.h`) will have the name `n_offset32` used for the `n_offset` field for XCOFF32, and the name `n_offset64` used for the `n_offset` field for XCOFF64.

## Understanding XCOFF

Assemblers and compilers produce XCOFF object files as output. The binder combines individual object files into an XCOFF executable file. The system loader reads an XCOFF executable file to create an executable memory image of a program. The symbolic debugger reads an XCOFF executable file to provide symbolic access to functions and variables of an executable memory image.

An XCOFF file contains the following parts:

- A composite header consisting of:
  - A file header

- An optional auxiliary header
- Section headers, one for each of the file's raw-data sections
- Raw-data sections, at most one per section header
- Optional relocation information for individual raw-data sections
- Optional line number information for individual raw-data sections
- An optional symbol table
- An optional string table, which is used for all symbol names in XCOFF64 and for symbol names longer than 8 bytes in XCOFF32.

Not every XCOFF file contains every part. A minimal XCOFF file contains only the file header.

### **Object and Executable Files**

XCOFF object files and executable files are similar in structure. An XCOFF executable file (or "module") must contain an auxiliary header, a loader section header, and a loader section.

The loader raw-data section contains information needed to dynamically load a module into memory for execution. Loading an XCOFF executable file into memory creates the following logical segments:

- A text segment (initialized from the .text section of the XCOFF file).
- A data segment, consisting of initialized data (initialized from the .data section of the XCOFF file) followed by uninitialized data (initialized to 0). The length of uninitialized data is specified in the .bss section header of the XCOFF file.

The XCOFF file Organization illustrates the structure of the XCOFF object file.

### **XCOFF Header Files**

The **xcoff.h** file defines the structure of the XCOFF file. The **xcoff.h** file includes the following files:

| Item                | Description                                             |
|---------------------|---------------------------------------------------------|
| <b>filehdr.h</b>    | Defines the file header.                                |
| <b>aouthdr.h</b>    | Defines the auxiliary header.                           |
| <b>scnhdr.h</b>     | Defines the section headers.                            |
| <b>loader.h</b>     | Defines the format of raw data in the .loader section.  |
| <b>typchk.h</b>     | Defines the format of raw data in the .typchk section.  |
| <b>exceptab.h</b>   | Defines the format of raw data in the .except section.  |
| <b>dbug.h</b>       | Defines the format of raw data in the .debug section.   |
| <b>reloc.h</b>      | Defines the relocation information.                     |
| <b>linenum.h</b>    | Defines the line number information.                    |
| <b>syms.h</b>       | Defines the symbol table format.                        |
| <b>storclass.h</b>  | Defines ordinary storage classes.                       |
| <b>dbxstclass.h</b> | Defines storage classes used by the symbolic debuggers. |

The **a.out.h** file includes the **xcoff.h** file. All of the XCOFF include files include the **xcoff32\_64.h** file.

For more information on sections of the XCOFF object file, see "Sections and Section Headers." For more information on the symbol table, see "Symbol Table Information." For more information on the string table, see "String Table." For more information on the Debug section, see "Debug Section."

### **Composite File Header**

The following sections describe the XCOFF composite file header components:

- File Header (filehdr.h)
- Auxiliary Header (aouthdr.h)

- Section Headers (scnhdr.h)

### File Header (filehdr.h)

The **filehdr.h** file defines the file header of an XCOFF file. The file header is 20 bytes long in XCOFF32 and 24 bytes long in XCOFF64. The structure contains the fields shown in the following table.

*Table 12. File Header Structure (Defined in filehdr.h)*

| Field Name and Description                                       | XCOFF32                                                                         | XCOFF64                                                                         |
|------------------------------------------------------------------|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>f_magic</b> Target machine                                    | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 2</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 2</li> </ul>  |
| <b>f_nscns</b> Number of sections                                | <ul style="list-style-type: none"> <li>Offset: 2</li> <li>Length: 2</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 2</li> <li>Length: 2</li> </ul>  |
| <b>f_timdat</b><br>Time and date of file creation                | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>  |
| <b>f_symptr</b><br>Byte offset to symbol table start             | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 8</li> </ul>  |
| <b>f_nsyms</b> <sup>+</sup><br>Number of entries in symbol table | <ul style="list-style-type: none"> <li>Offset: 12</li> <li>Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 20</li> <li>Length: 4</li> </ul> |
| <b>f_opthdr</b><br>Number of bytes in optional header            | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 2</li> </ul> |
| <b>f_flags</b> Flags (see "Field Definitions")                   | <ul style="list-style-type: none"> <li>Offset: 18</li> <li>Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 18</li> <li>Length: 2</li> </ul> |

**Note:** + Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.

### Field Definitions

| Item            | Description                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>f_magic</b>  | Specifies an integer known as the <i>magic number</i> , which specifies the target machine and environment of the object file. For XCOFF32, the only valid value is 0x01DF (0737 Octal). For XCOFF64 the only valid value is 0x01F7 (0767 Octal). Symbolic names for these values are found in the file, <b>/usr/include/filehdr.h</b> . |
| <b>f_nscns</b>  | Specifies the number of section headers contained in the file. The first section header is section header number one; all references to a section are one-based.                                                                                                                                                                         |
| <b>f_timdat</b> | Specifies when the file was created (number of elapsed seconds since 00:00:00 Universal Coordinated Time (UCT), January 1, 1970). This field should specify either the actual time or be set to a value of 0.                                                                                                                            |
| <b>f_symptr</b> | Specifies a file pointer (byte offset from the beginning of the file) to the start of the symbol table. If the value of the <b>f_nsyms</b> field is 0, then <b>f_nsyms</b> is undefined.                                                                                                                                                 |
| <b>f_nsyms</b>  | Specifies the number of entries in the symbol table. Each symbol table entry is 18 bytes long.                                                                                                                                                                                                                                           |
| <b>f_opthdr</b> | Specifies the length, in bytes, of the auxiliary header. For an XCOFF file to be executable, the auxiliary header must exist and be <b>_AOUTHSZ_EXEC</b> bytes long. ( <b>_AOUTHSZ_EXEC</b> is defined in <b>aouthdr.h</b> .)                                                                                                            |

| Item               | Description                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| f_flags            | Specifies a bit mask of flags that describe the type of the object file. The following information defines the flags:                                                                                                                      |
| Bit Mask           |                                                                                                                                                                                                                                            |
|                    | Flag                                                                                                                                                                                                                                       |
| 0x0001 F_RELFLG    | Indicates that the relocation information for binding has been removed from the file. This flag must not be set by compilers, even if relocation information was not required.                                                             |
| 0x0002 F_EXEC      | Indicates that the file is executable. No unresolved external references exist.                                                                                                                                                            |
| 0x0004 F_LNNO      | Indicates that line numbers have been stripped from the file by a utility program. This flag is not set by compilers, even if no line-number information has been generated.                                                               |
| 0x0008 Reserved.   |                                                                                                                                                                                                                                            |
| 0x0010 F_FDPR_PROF | Indicates that the file was profiled with the <b>fdpr</b> command.                                                                                                                                                                         |
| 0x0020 F_FDPR_OPTI | Indicates that the file was reordered with the <b>fdpr</b> command.                                                                                                                                                                        |
| 0x0040 F_DSA       | Indicates that the file uses Very Large Program Support.                                                                                                                                                                                   |
| 0x0080 Reserved.   |                                                                                                                                                                                                                                            |
| 0x0100 F_VARPG     | Indicates that one of the members of the auxiliary header specifying the medium page sizes is non-zero. By default, the value of this bit is always zero.                                                                                  |
| 0x0200 Reserved.   |                                                                                                                                                                                                                                            |
| 0x0400 Reserved.   |                                                                                                                                                                                                                                            |
| 0x0800 Reserved.   |                                                                                                                                                                                                                                            |
| 0x1000 F_DYNLOAD   | Indicates the file is dynamically loadable and executable. External references are resolved by way of imports, and the file might contain exports and loader relocation.                                                                   |
| 0x2000 F_SHROBJ    | Indicates the file is a shared object (shared library). The file is separately loadable. That is, it is not normally bound with other objects, and its loader exports symbols are used as automatic import symbols for other object files. |
| 0x4000 F_LOADONLY  | If the object file is a member of an archive, it can be loaded by the system loader, but the member is ignored by the binder. If the object file is not in an archive, this flag has no effect.                                            |
| 0x8000 Reserved.   |                                                                                                                                                                                                                                            |

## Auxiliary Header (aouthdr.h)

The auxiliary header contains system-dependent and implementation-dependent information, which is used for loading and executing a module. Information in the auxiliary header minimizes how much of the file must be processed by the system loader at execution time.

The binder generates an auxiliary header for use by the system loader. Auxiliary headers are not required for an object file that is not to be loaded. When auxiliary headers are generated by compilers and assemblers, the headers are ignored by the binder.

The auxiliary header immediately follows the file header.

**Note:** If the value of the `f_opthdr` field in the file header is 0, the auxiliary header does not exist.

The C language structure for the auxiliary header is defined in the `aouthdr.h` file. The auxiliary header contains the fields shown in the following table.

*Table 13. Auxiliary Header Structure (Defined in aouthdr.h)*

| Field Name and Description                                                       | XCOFF32                                                                             | XCOFF64                                                                             |
|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|

**Note:** + Use "32" or "64" suffix when \_\_XCOFF\_HYBRID\_\_ is defined.

## Field Definitions

The following information defines the auxiliary header fields. For entries with two labels, the label in parentheses is the alternate original COFF **a.out** file format name.

| Item                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>o_mflags (magic)</code>          | If the value of the <code>o_vstamp</code> field is greater than 1, the <code>o_mflags</code> field is reserved for future use and it should contain 0. Otherwise, this field is not used.                                                                                                                                                                                                                                                                                                                     |
| <code>o_vstamp (vstamp)</code>         | Specifies the format version for this auxiliary header. The valid values are 1 and 2. When the <code>o_vstamp</code> field is 2 in an XCOFF32 file, the new interpretation of the <code>n_type</code> field in the symbol table entry is used.                                                                                                                                                                                                                                                                |
| <code>o_tsize (tsize)</code>           | Specifies the size (in bytes) of the raw data for the <code>.text</code> section. The <code>.text</code> section typically contains the read-only part of the program. This is the same value as contained in the <code>s_size</code> field of the section header for the <code>.text</code> section.                                                                                                                                                                                                         |
| <code>o_dsize (dsiz)</code>            | Specifies the size (in bytes) of the raw data for the <code>.data</code> section. The <code>.data</code> section contains the initialized data of the program and is writable. This is the same value as contained in the <code>s_size</code> field of the section header for the <code>.data</code> section.                                                                                                                                                                                                 |
| <code>o_bsize (bsize)</code>           | Specifies the size (in bytes) of <code>.bss</code> area, which is used for uninitialized variables during execution and is writable. No raw data exists in the file for the <code>.bss</code> section. This is the same value as contained in the <code>s_size</code> field of the section header for the <code>.bss</code> section.                                                                                                                                                                          |
| <code>o_entry (entry)</code>           | Specifies the virtual address of the entry point. (See the definition of the <code>o_snentry</code> field.) For application programs, this virtual address is the address of the function descriptor. The function descriptor contains the addresses of both the entry point itself and its TOC anchor. The offset of the entry point function descriptor from the beginning of its containing section can be calculated as follows:<br><br><code>Section_offset_value=o_entry-s_paddr[o_snentry - 1],</code> |
|                                        | where <code>s_paddr</code> is the virtual address contained in the specified section header.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>o_text_start (text_start)</code> | Specifies the virtual address of the <code>.text</code> section. This is the address assigned to (that is, used for) the first byte of the <code>.text</code> raw-data section. This is the same value as contained in the <code>s_paddr</code> field of the section header for the <code>.text</code> section.                                                                                                                                                                                               |
| <code>o_data_start (data_start)</code> | Specifies the virtual address of the <code>.data</code> section. This is the address assigned to (that is, used for) the first byte of the <code>.data</code> raw-data section. This is the same value as contained in the <code>s_paddr</code> field of the section header for the <code>.data</code> section.                                                                                                                                                                                               |
|                                        | For addressing purposes, the <code>.bss</code> section is considered to follow the <code>.data</code> section.                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>o_toc</code>                     | Specifies the virtual address of the TOC anchor (see the definition of the <code>o_sntoc</code> field).                                                                                                                                                                                                                                                                                                                                                                                                       |
| <code>o_snentry</code>                 | Specifies the number of the file section containing the entry-point. (This field contains a file section header sequence number.) The entry point must be in the <code>.text</code> or <code>.data</code> section.                                                                                                                                                                                                                                                                                            |
| <code>o_sntext</code>                  | Specifies the number of the file <code>.text</code> section. (This field contains a file section header sequence number.)                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>o_sndata</code>                  | Specifies the number of the file <code>.data</code> section. (This field contains a file section header sequence number.)                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>o_sntoc</code>                   | Specifies the number of the file section containing the TOC. (This field contains a file section header sequence number.)                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>o_snloader</code>                | Specifies the number of the file section containing the system loader information. (This field contains a file section header sequence number.)                                                                                                                                                                                                                                                                                                                                                               |
| <code>o_snbs</code>                    | Specifies the number of the file <code>.bss</code> section. (This field contains a file section header sequence number.)                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>o_algntext</code>                | Specifies the log (base 2) of the maximum alignment needed for any csect in the <code>.text</code> section.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>o_algnodata</code>               | Specifies the log (base 2) of the maximum alignment needed for any csect in the <code>.data</code> and <code>.bss</code> sections.                                                                                                                                                                                                                                                                                                                                                                            |
| <code>o_modtype</code>                 | Specifies a module type. The value is an ASCII character string. The following module type is recognized by the system loader:<br><br><b>RO</b> Specifies a read-only module. If a shared object with this module type has no BSS section and only depends on other read-only modules, the data section of the module will be mapped read-only and shared by all processes using the object.                                                                                                                  |
| <code>o_cpuflag</code>                 | Bit flags - cputypes of objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>o_cputype</code>                 | Reserved. The default value is 0 (system-selected page size).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                                   |                 |           |               |                    |               |                     |                  |           |
| <code>o_datapsize</code>  | Specifies the size of pages for the exec data. The default value is 0 (system-selected page size). The value of <code>o_datapsize</code> overrides the large page data request (by setting the F_LPDATA bit in the XCOFF file).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                |                                   |                 |           |               |                    |               |                     |                  |           |
| <code>o_stackpsize</code> | Specifies the size of pages for the stack. The default value is 0 (system-selected page size).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                                   |                 |           |               |                    |               |                     |                  |           |
| <code>o_x64flags</code>   | Consists of 16 flag bits. This field only exists in the <b>XCOFF64</b> definition.<br><br><b>_AOUT_SHR_SYMTAB 0x8000</b><br>Requests the creation of shared symbol table be created for this program, which is used by all instances of the program on the system. This flag is ignored in a shared library.<br><br><b>_AOUT_FORK_POLICY 0x4000</b><br>If the <b>_AOUT_FORK_POLICY</b> flag is set, an explicit forktree policy is requested. The <b>_AOUT_FORK_COR</b> flag determines which policy is requested. This flag is ignored in a shared library.<br><br><b>_AOUT_FORK_COR 0x2000</b><br>If the <b>_AOUT_FORK_POLICY</b> and <b>_AOUT_FORK_COR</b> flags are both set, the copy-on-reference forktree policy is requested. If the <b>_AOUT_FORK_POLICY</b> flag is set but the <b>_AOUT_FORK_COR</b> flag is not set, the copy-on-write forktree policy is requested.<br>If the <b>_AOUT_FORK_POLICY</b> is not set, the <b>_AOUT_FORK_COR</b> flag is reserved for future use and should be set to 0. This flag is ignored in a shared library. |                |                                   |                 |           |               |                    |               |                     |                  |           |

In general, an object file might contain multiple sections of a given type, but in a loadable module, there must be exactly one .text, .data, .bss, and .loader section. A loadable object might also have one .tdata section and one.tbss section.

### Section Headers (scnhdr.h)

Each section of an XCOFF file has a corresponding section header, although some section headers may not have a corresponding raw-data section. A section header provides identification and file-accessing information for each section contained within an XCOFF file. Each section header in an XCOFF32 file is 40 bytes long, while XCOFF64 section headers are 72 bytes long. The C language structure for a section header can be found in the **scnhdr.h** file. A section header contains the fields shown in the following table.

*Table 14. Section Header Structure (Defined in scnhdr.h)*

| Field Name and Description                                                         | XCOFF32                                                                             | XCOFF64                                                                             |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>s_name</b> Section name                                                         | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul>  |
| <b>s_paddr</b> <sup>+</sup><br>Physical address                                    | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 8</li> </ul>  |
| <b>s_vaddr</b> <sup>+</sup><br>Virtual address (same as physical address)          | <ul style="list-style-type: none"> <li>• Offset: 12</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 8</li> </ul> |
| <b>s_size</b> <sup>+</sup> Section size                                            | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 24</li> <li>• Length: 8</li> </ul> |
| <b>s_scnptr</b> <sup>+</sup><br>Offset in file to raw data for section             | <ul style="list-style-type: none"> <li>• Offset: 20</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 32</li> <li>• Length: 8</li> </ul> |
| <b>s_relptra</b> <sup>+</sup><br>Offset in file to relocation entries for section  | <ul style="list-style-type: none"> <li>• Offset: 24</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 40</li> <li>• Length: 8</li> </ul> |
| <b>s_lnnoptr</b> <sup>+</sup><br>Offset in file to line number entries for section | <ul style="list-style-type: none"> <li>• Offset: 28</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 48</li> <li>• Length: 8</li> </ul> |
| <b>s_nreloc</b> <sup>+</sup><br>Number of relocation entries                       | <ul style="list-style-type: none"> <li>• Offset: 32</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 56</li> <li>• Length: 4</li> </ul> |
| <b>s_nlnno</b> <sup>+</sup><br>Number of line number entries                       | <ul style="list-style-type: none"> <li>• Offset: 34</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 60</li> <li>• Length: 4</li> </ul> |
| <b>s_flags</b> <sup>+</sup><br>Flags to define the section type                    | <ul style="list-style-type: none"> <li>• Offset: 36</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 64</li> <li>• Length: 4</li> </ul> |

**Note:** + Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.

## Field Definitions

The following information defines the section header fields:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>s_name</b>    | Specifies an 8-byte, null-padded section name. An 8-byte section name will not have a terminating null character. Use the <b>s_flags</b> field instead of the <b>s_name</b> field to determine a section type. Two sections of the same type may have different names, allowing certain applications to distinguish between them.                                                                                                                                |
| <b>s_paddr</b>   | Specifies the physical address of the section. This is the address assigned and used by the compilers and the binder for the first byte of the section. This field should contain 0 for all sections except the <b>.text</b> , <b>.data</b> , and <b>.bss</b> sections.                                                                                                                                                                                          |
| <b>s_vaddr</b>   | Specifies the virtual address of the section. This field has the same value as the <b>s_paddr</b> field.                                                                                                                                                                                                                                                                                                                                                         |
| <b>s_size</b>    | Specifies the size (in bytes) of this section.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>s_scnptr</b>  | Specifies a file pointer (byte offset from the beginning of the file) to this section's raw data. If this field contains 0, this section has no raw data. Otherwise, the size of the raw data must be contained in the <b>s_size</b> field.                                                                                                                                                                                                                      |
| <b>s_relptra</b> | Specifies a file pointer (byte offset from the beginning of the file) to the relocation entries for this section. If this section has no relocation entries, this field must contain 0.                                                                                                                                                                                                                                                                          |
| <b>s_lnnoptr</b> | Specifies a file pointer (byte offset from the beginning of the file) to the line number entries for this section. If this section has no line number entries, this field must contain 0.                                                                                                                                                                                                                                                                        |
| <b>s_nreloc</b>  | Specifies the number of relocation entries for this section. In an XCOFF32 file, if more than 65,534 relocation entries are required, the field value will be 65535, and an <b>STYP_OVRFLO</b> section header will contain the actual count of relocation entries in the <b>s_paddr</b> field. Refer to the discussion of overflow headers in "Sections and Section Headers". If this field is set to 65535, the <b>s_nlnno</b> field must also be set to 65535. |

| Item                                                                                                                                                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s_nlnno                                                                                                                                                                                                                                                                  | Specifies the number of line number entries for this section. In an XCOFF32 file, if more than 65,534 line number entries are required, the field value will be 65535, and an <b>STYP_OVRFL0</b> section header will contain the actual number of line number entries in the s_yaddr field. Refer to the discussion of overflow headers in "Sections and Section Headers". If this field is set to 65535, the s_nrelloc field must also be set to 65535. |
| s_flags                                                                                                                                                                                                                                                                  | Specifies flags defining the section type. The low-order pair of bytes is used. A section type identifies the contents of a section and specifies how the section is to be processed by the binder or the system loader. Only a single bit value may be assigned to the s_flags field. This value must not be the sum or bitwise OR of multiple flags. The two high-order bytes should contain 0.                                                        |
| Valid bit values are:                                                                                                                                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Value</b>                                                                                                                                                                                                                                                             | <b>Flag</b>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 0x0000                                                                                                                                                                                                                                                                   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0x0001                                                                                                                                                                                                                                                                   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Specifies a pad section. A section of this type is used to provide alignment padding between sections within an XCOFF executable object file. This section header type is obsolete since padding is allowed in an XCOFF file without a corresponding pad section header. |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <code>0x1000</code>            | <code>STYP_LOADER</code>                                                                                                                                                                                                                                                                                                                                                                                 |
|                                | Specifies a loader section. A section of this type contains object file information for the system loader to load an XCOFF executable. The information includes imported symbols, exported symbols, relocation data, type-check information, and shared object names.                                                                                                                                    |
| <code>0x2000</code>            | <code>STYP_DEBUG</code>                                                                                                                                                                                                                                                                                                                                                                                  |
|                                | Specifies a debug section. A section of this type contains stabstring information used by the symbolic debugger.                                                                                                                                                                                                                                                                                         |
| <code>0x4000</code>            | <code>STYP_TYPCHK</code>                                                                                                                                                                                                                                                                                                                                                                                 |
|                                | Specifies a type-check section. A section of this type contains parameter/argument type-check strings used by the binder.                                                                                                                                                                                                                                                                                |
| <code>0x8000</code>            | <code>STYP_OVRFLO</code>                                                                                                                                                                                                                                                                                                                                                                                 |
|                                | <b>Note:</b> An XCOFF64 file may not contain an overflow section header.                                                                                                                                                                                                                                                                                                                                 |
|                                | Specifies a relocation or line-number field overflow section. A section header of this type contains the count of relocation entries and line number entries for some other section. This section header is required when either of the counts exceeds 65,534. See the <code>s_nreloc</code> and <code>s_nlnno</code> fields in "Sections and Section Headers" for more information on overflow headers. |

## Sections and Section Headers

Section headers are defined to provide a variety of information about the contents of an XCOFF file. Programs that process XCOFF files will recognize only some of the valid sections.

See the following information to learn more about XCOFF file sections:

- Loader Section (`loader.h`)
- Debug Section
- Type-Check Section
- Exception Section
- Comment Section

Current applications do not use the `s_name` field to determine the section type. Nevertheless, conventional names are used by system tools, as shown in the following table.

*Table 15. Conventional Header Names*

| <b>Description</b> | <b>Multiple Allowed?</b>                                       | <b><code>s_flag</code> (and its conventional name)</b> |
|--------------------|----------------------------------------------------------------|--------------------------------------------------------|
| Text section       | Yes                                                            | <code>STYP_TEXT (.text)</code>                         |
| Data section       | Yes                                                            | <code>STYP_DATA (.data)</code>                         |
| BSS section        | Yes                                                            | <code>STYP_BSS (.bss)</code>                           |
| Pad section        | Yes                                                            | <code>STYP_PAD (.pad)</code>                           |
| Loader section     | No                                                             | <code>STYP_LOADER (.loader)</code>                     |
| Debug section      | No                                                             | <code>STYP_DEBUG (.debug)</code>                       |
| Type-check section | Yes                                                            | <code>STYP_TYPCHK (.typchk)</code>                     |
| Exception section  | No                                                             | <code>STYP_EXCEPT (.except)</code>                     |
| Overflow section   | Yes (one per <code>.text</code> or <code>.data</code> section) | <code>STYP_OVRFLO (.ovrflo)</code>                     |
| Comment section    | Yes                                                            | <code>STYP_INFO (.info)</code>                         |
| Tdata section      | Yes                                                            | <code>STYP_TDATA (.tdata)</code>                       |
| TBSS section       | Yes                                                            | <code>STYP_TBSS (.tbss)</code>                         |

Some fields of a section header may not always be used, or may have special usage. This pertains to the following fields:

| Item               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s_name             | On input, ignored by the binder and system loader. On output, the conventional names (shown in the "Conventional Header Names" table) are used.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| s_scnptr           | Ignored for .bss sections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| s_relptr           | Recognized for the .text , .data , and .tdata sections only. No relocation is performed for other sections, where this value must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| s_lnnoptr          | Recognized for the .text section only. Otherwise, it must be 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| s_nreloc , s_nlnno | Handles relocation or line-number field overflows in an XCOFF32 file. (XCOFF64 files may not have overflow section headers.) If a section has more than 65,534 relocation entries or line number entries, both of these fields are set to a value of 65535. In this case, an overflow section header with the s_flags field equal to <b>STYP_OVRFLO</b> is used to contain the relocation and line-number count information. The fields in the overflow section header are defined as follows:                                                                                     |
| <b>s_nreloc</b>    | Specifies the file section number of the section header that overflowed; that is, the section header containing a value of 65535 in its s_nreloc and s_nlnno fields. This value provides a reference to the primary section header. This field must have the same value as the s_nlnno field.<br><b>Note:</b> There is no reference in the primary section header that identifies the appropriate overflow section header. All the section headers must be searched to locate an overflow section header that contains the correct primary section header reference in this field. |
| <b>s_nlnno</b>     | Specifies the file section number of the section header that overflowed. This field must have the same value as the s_nreloc field.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>s_paddr</b>     | Specifies the number of relocation entries actually required. This field is used instead of the s_nreloc field of the section header that overflowed.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>s_vaddr</b>     | Specifies the number of line-number entries actually required. This field is used instead of the s_nlnno field of the section header that overflowed.                                                                                                                                                                                                                                                                                                                                                                                                                              |

The s\_size and s\_scnptr fields have a value of 0 in an overflow section header. The s\_relptr and s\_lnnoptr fields must have the same values as in the corresponding primary section header.

An XCOFF file provides special meaning to the following sections:

- The .text, .data, and .bss sections, and the optional .tdata and .tbss sections, define the memory image of the program. The relocation parts associated with the .text and .data sections contain the full binder relocation information so it can be used for replacement link editing. Only the .text section is associated with a line number part. The parts associated with the executable code are produced by the compilers and assemblers.
- The .pad section is defined as a null-filled, raw-data section that is used to align a subsequent section in the file on some defined boundary such as a file block boundary or a system page boundary. Padding is allowed in an XCOFF file without a corresponding section header so that the binder does not generate pad section headers.
- The .loader section is a raw-data section defined to contain the dynamic loader information. This section is generated by the binder and has its own self-contained symbol table and relocation table. There is no reference to this section from the XCOFF Symbol Table.
- The .debug section is a raw-data section defined to contain the stab (symbol table) or dictionary information required by the symbolic debugger.
- The .typchk section is a raw-data section defined to contain parameter and argument type-checking strings.
- The .except section is a raw-data section defined to contain the exception tables used to identify the reasons for an exception in program execution.
- The .info comment section is a raw-data section defined to contain comments or data that are of significance to special processing utility programs.
- The .debug, .except, .info, and .typchk sections are produced by compilers and assemblers. References to these sections or to items within these sections are made from the XCOFF Symbol Table.

For more information on XCOFF file sections, see "Loader Section (`loader.h`)," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Loader Section (`loader.h`)

The loader section contains information required by the system loader to load and relocate an executable XCOFF object. The loader section is generated by the binder. The loader section has an `s_flags` section type flag of `STYP_LOADER` in the XCOFF section header. By convention, `.loader` is the loader section name. The data in this section is not referenced by entries in the XCOFF symbol table.

The loader section consists of the following parts:

- Header fields
- Symbol table
- Relocation table
- Import file ID strings
- Symbol name string table

The C language structure for the loader section can be found in the `loader.h` file.

### Loader Header Field Definitions

The following table describes the loader section's header field definitions.

*Table 16. Loader Section Header Structure (Defined in `loader.h`)*

| Field Name and Description                                              | XCOFF32                                                                                | XCOFF64                                                                             |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <code>l_version</code><br>Loader section version number                 | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul>  |
| <code>l_nsyms</code> Number of symbol table entries                     | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 4</li> </ul>  |
| <code>l_nreloc</code><br>Number of relocation table entries             | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul>  |
| <code>l_islen</code><br>Length of import file ID string table           | <ul style="list-style-type: none"> <li>• Offset: 12</li> <li>• Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 12</li> <li>• Length: 4</li> </ul> |
| <code>l_nimpid</code><br>Number of import file IDs                      | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 4</li> </ul> |
| <code>l_impoft<sup>+</sup></code><br>Offset to start of import file IDs | <ul style="list-style-type: none"> <li>• Offset: 20</li> <li>• Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 24</li> <li>• Length: 8</li> </ul> |
| <code>l_stlen<sup>+</sup></code><br>Length of string table              | <ul style="list-style-type: none"> <li>• Offset: 24</li> <li>• Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 20</li> <li>• Length: 4</li> </ul> |
| <code>l_stoff<sup>+</sup></code><br>Offset to start of string table     | <ul style="list-style-type: none"> <li>• Offset: 28</li> <li>• Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 32</li> <li>• Length: 8</li> </ul> |
| <code>l_symoff</code><br>Offset to start of symbol table                | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 40</li> <li>• Length: 8</li> </ul> |
| <code>l_rloff</code> Offset to start of relocation entries              | <ul style="list-style-type: none"> <li>• Offset: 36</li> <li>• Length: 2</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 64</li> <li>• Length: 4</li> </ul> |

**Note:** +Use "32" or "64" suffix when `__XCOFF_HYBRID__` is defined

The following information defines the loader section's header fields:

| Item                   | Description                                                                                                                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l_version</code> | Specifies the loader section version number. This value must be 1 for XCOFF32, 2 for XCOFF64.                                                                                                                                                                                                      |
| <code>l_nsyms</code>   | Specifies the number of symbol table entries in the loader section. This value is the actual count of symbol table entries contained in the loader section and does not include the three implicit entries for the <code>.text</code> , <code>.data</code> , and <code>.bss</code> symbol entries. |
| <code>l_nreloc</code>  | Specifies the number of relocation table entries in the loader section.                                                                                                                                                                                                                            |
| <code>l_istlen</code>  | Specifies the byte length of the import file ID string table in the loader section.                                                                                                                                                                                                                |
| <code>l_nimpid</code>  | Specifies the number of import file IDs in the import file ID string table.                                                                                                                                                                                                                        |
| <code>l_imoff</code>   | Specifies the byte offset from beginning of the loader section to the first import file ID.                                                                                                                                                                                                        |
| <code>l_stlen</code>   | Specifies the length of the loader section string table.                                                                                                                                                                                                                                           |
| <code>l_stoff</code>   | Specifies the byte offset from beginning of the loader section to the first entry in the string table.                                                                                                                                                                                             |
| <code>l_symoff</code>  | Specifies the byte offset from beginning of the loader section to the start of the loader symbol table (in XCOFF64 only).                                                                                                                                                                          |
| <code>l_rloff</code>   | Specifies the byte offset from beginning of the loader section to the start of the loader section relocation entries (in XCOFF64 only).                                                                                                                                                            |

## Loader Symbol Table Field Definitions

The loader section symbol table contains the symbol table entries that the system loader needs for its import and export symbol processing and dynamic relocation processing.

The `loader.h` file defines the symbol table fields. Each entry is 24 bytes long.

There are five implicit external symbols, one each for the `.text`, `.data`, `.bss`, `.tdata`, and `.tbss` sections. These symbols are referenced from the relocation table entries using symbol table index values 0, 1, 2, -1, and -2, respectively.

*Table 17. Loader Section Symbol Table Entry Structure*

| Field Name and Description                                                                             | XCOFF32                                                                         | XCOFF64                                                                            |
|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <code>l_name</code> <sup>+</sup> Symbol name or byte offset into string table                          | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 8</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> |
| <code>l_zeroes</code> <sup>+</sup> Zero indicates symbol name is referenced from <code>l_offset</code> | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> |
| <code>l_offset</code> <sup>+</sup> Byte offset into string table of symbol name                        | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 4</li> </ul>     |
| <code>l_value</code> <sup>+</sup> Address field                                                        | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 8</li> </ul>     |
| <code>l_scnum</code> Section number containing symbol                                                  | <ul style="list-style-type: none"> <li>Offset: 12</li> <li>Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 12</li> <li>Length: 2</li> </ul>    |
| <code>l_smtype</code> Symbol type, export, import flags                                                | <ul style="list-style-type: none"> <li>Offset: 14</li> <li>Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 14</li> <li>Length: 1</li> </ul>    |
| <code>l_smclas</code> Symbol storage class                                                             | <ul style="list-style-type: none"> <li>Offset: 15</li> <li>Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 15</li> <li>Length: 1</li> </ul>    |
| <code>l_ifile</code> Import file ID; ordinal of import file IDs                                        | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 4</li> </ul>    |
| <code>l_parm</code> Parameter type-check field                                                         | <ul style="list-style-type: none"> <li>Offset: 20</li> <li>Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 20</li> <li>Length: 4</li> </ul>    |

**Note:** +Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.

The symbol table fields are:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l_name</b>   | (XCOFF32 only) Specifies an 8-byte, null-padded symbol name if it is 8 bytes or less in length. Otherwise, the field is treated as the following two 4-byte integers for accessing the symbol name:                                                                                                                                                                                                                                                                                                        |
| <b>l_zeroes</b> | (XCOFF32 only) A value of 0 indicates that the symbol name is in the loader section string table. This field overlays the first word of the l_name field. An l_name field having the first 4 bytes (first word) equal to 0 is used to indicate that the name string is contained in the string table instead of the l_name field.                                                                                                                                                                          |
| <b>l_offset</b> | (XCOFF32 only) This field overlays the second word of the l_name field. The value of this field is the byte offset from the beginning of the loader section string table to the first byte of the symbol name (not its length field).                                                                                                                                                                                                                                                                      |
| <b>l_offset</b> | (XCOFF64 only) This field has the same use as the l_offset field in XCOFF32.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>l_value</b>  | Specifies the virtual address of the symbol                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>l_scnum</b>  | Specifies the number of the XCOFF section that contains the symbol. If the symbol is undefined or imported, the section number is 0. Otherwise, the section number refers to the .text, .data, or .bss section. Section headers are numbered beginning with 1.                                                                                                                                                                                                                                             |
| <b>l_smtype</b> | Specifies the symbol type, import flag, export flag, and entry flag.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|                 | Bits 0-4 are flag bits defined as follows:                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                 | <ul style="list-style-type: none"> <li><b>Bit 0</b> 0x80 Reserved.</li> <li><b>Bit 1</b> 0x40 Specifies an imported symbol.</li> <li><b>Bit 2</b> 0x20 Specifies an entry point descriptor symbol.</li> <li><b>Bit 3</b> 0x10 Specifies an exported symbol.</li> <li><b>Bit 4</b> 0x08 Specifies a weak symbol.</li> <li><b>Bits 5-7</b> 0x07 Symbol type--see below.</li> </ul>                                                                                                                           |
|                 | Bits 5-7 constitute a 3-bit symbol type field with the following definitions:                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>0</b>        | <b>XTY_ER</b><br>Specifies an external reference providing a symbol table entry for an external (global) symbol contained in another XCOFF object file.                                                                                                                                                                                                                                                                                                                                                    |
| <b>1</b>        | <b>XTY_SD</b><br>Specifies the csect section definition, providing the definition of the smallest initialized unit within an XCOFF object file.                                                                                                                                                                                                                                                                                                                                                            |
| <b>2</b>        | <b>XTY_LD</b><br>Specifies the label definition, providing the definition of the global entry points for initialized csects. An uninitialized csect of type <b>XTY_CM</b> may not contain a label definition.                                                                                                                                                                                                                                                                                              |
| <b>3</b>        | <b>XTY_CM</b><br>Specifies a common (BSS uninitialized data) csect definition, providing the definition of the smallest uninitialized unit within an XCOFF object file.                                                                                                                                                                                                                                                                                                                                    |
| <b>4-7</b>      | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>l_smclas</b> | Specifies the storage mapping class of the symbol, as defined in <b>syms.h</b> for the x_smclas field of the csect auxiliary symbol table entry. Values have the symbolic form XMC_xx, where xx is PR, RO, GL, XO, SV, SV64, SV3264, RW, TC, TD, DS, UA, BS, UC, TL, or UL. See "csect Auxiliary Entry for the <b>C_EXT</b> , <b>C_WEAKEXT</b> , and <b>C_HIDEEXT</b> Symbols" for more information.                                                                                                       |
| <b>l_ifile</b>  | Specifies the import file ID string. This integer is the ordinal value of the position of the import file ID string in the import file ID name string table of the loader section. For an imported symbol, the value of 0 in this field identifies the symbol as a deferred import to the system loader. A deferred import is a symbol whose address can remain unresolved following the processing of the loader. If the symbol was not imported, this field must have a value of 0.                      |
| <b>l_parm</b>   | Specifies the offset to the parameter type-check string. The byte offset is from the beginning of the loader section string table. The byte offset points to the first byte of the parameter type-check string (not to its length field). For more information on the parameter type-check string, see "Type-Check Section". A value of 0 in the l_parm field indicates that the parameter type-checking string is not present for this symbol, and the symbol will be treated as having a universal hash. |

## Loader Relocation Table Field Definitions

The Loader Section Relocation Table Structure contains all of the relocation information that the system loader needs to properly relocate an executable XCOFF file when it is loaded. The **loader.h** file defines the relocation table fields. Each entry in the loader section relocation table is 12 bytes long in XCOFF32, and 16 bytes long in XCOFF64. The **l\_vaddr**, **l\_symndx**, and **l\_rtype** fields have the same meaning as the corresponding fields of the regular relocation entries, which are defined in the **reloc.h** file. For more information about relocation entries, see Relocation Information for XCOFF File (reloc.h).

*Table 18. Loader Section Relocation Table Entry Structure*

| Field Name and Description                                                           | XCOFF32                                                                          | XCOFF64                                                                          |
|--------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>l_vaddr</b> <sup>+</sup><br>Address field                                         | <ul style="list-style-type: none"><li>• Offset: 0</li><li>• Length: 4</li></ul>  | <ul style="list-style-type: none"><li>• Offset: 0</li><li>• Length: 8</li></ul>  |
| <b>l_symndx</b> <sup>+</sup><br>Loader section symbol table index of referenced item | <ul style="list-style-type: none"><li>• Offset: 4</li><li>• Length: 4</li></ul>  | <ul style="list-style-type: none"><li>• Offset: 12</li><li>• Length: 4</li></ul> |
| <b>l_rtype</b> Relocation type                                                       | <ul style="list-style-type: none"><li>• Offset: 4</li><li>• Length: 4</li></ul>  | <ul style="list-style-type: none"><li>• Offset: 8</li><li>• Length: 4</li></ul>  |
| <b>l_value</b> <sup>+</sup><br>Address field                                         | <ul style="list-style-type: none"><li>• Offset: 8</li><li>• Length: 2</li></ul>  | <ul style="list-style-type: none"><li>• Offset: 8</li><li>• Length: 2</li></ul>  |
| <b>l_rsecnm</b><br>File section number being relocated                               | <ul style="list-style-type: none"><li>• Offset: 10</li><li>• Length: 2</li></ul> | <ul style="list-style-type: none"><li>• Offset: 10</li><li>• Length: 2</li></ul> |

**Note:** + Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.

The **loader.h** file defines the following fields:

| Name            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l_vaddr</b>  | Specifies the virtual address of the relocatable reference.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>l_symndx</b> | Specifies the loader section symbol table index ( <i>n</i> -th entry) of the symbol that is being referenced. Values 0, 1, and 2 are implicit references to .text, .data, and .bss sections, respectively. Symbol index 3 is the index for the first symbol actually contained in the loader section symbol table.<br><b>Note:</b> A reference to an exported symbol can be made using the symbol's section number (symbol number 0, 1, or 2) or using the actual number of the exported symbol. |
| <b>l_rtype</b>  | Specifies the relocation size and type. (This field has the same interpretation as the <b>r_type</b> field in the <b>reloc.h</b> file.) For more information about relocation entries, see Relocation Information for XCOFF File (reloc.h).                                                                                                                                                                                                                                                      |
| <b>l_rsecnm</b> | Specifies the section number of the sections being relocated. This is a one-based index into the section headers.                                                                                                                                                                                                                                                                                                                                                                                |

## Loader Import File ID Name Table Definition

The loader section import file ID name strings of a module provide a list of dependent modules that the system loader must load in order for the module to load successfully. However, this list does not contain the names of modules that the named modules depend on.

*Table 19. Loader Section Import File IDs - Contains Variable Length Strings*

| Offset          | Length in Bytes | Name and Description                                                                            |
|-----------------|-----------------|-------------------------------------------------------------------------------------------------|
| 0               | $n_1$           | $l\_impidpath$<br>Import file ID path string, null-delimited                                    |
| $n_1 + 1$       | $n_2$           | $l\_impidbase$<br>Import file ID base string, null-delimited                                    |
| $n_1 + n_2 + 2$ | $n_3$           | $l\_impidmem$<br>Import file ID member string, null-delimited<br>Fields repeat for each string. |

Each import file ID name consists of three null-delimited strings.

The first import file ID is a default **LIBPATH** value to be used by the system loader. The **LIBPATH** information consists of file paths separated by colons. There is no base name or archive member name, so the file path is followed by three null bytes.

Each entry in the import file ID name table consists of:

- Import file ID path name
- Null delimiter (ASCII null character)
- Import file ID base name
- Null delimiter
- Import file ID archive-file-member name
- Null delimiter

For example:

/usr/lib\0mylib.a\0shr.o\0

#### Loader String Table Definition

The loader section string table contains the parameter type-checking strings, all symbols names for an XCOFF64 file, and the names of symbols longer than 8 bytes for an XCOFF32 file. Each string consists of a 2-byte length field followed by the string.

*Table 20. Loader Section String Table*

| Offset | Length in Bytes | Description                                                                        |
|--------|-----------------|------------------------------------------------------------------------------------|
| 0      | 2               | Length of string.                                                                  |
| 2      | $n$             | Symbol name string (null-delimited) or parameter type string (not null-delimited). |
|        |                 | Fields repeat for each string.                                                     |

Symbol names are null-terminated. The value in the length-field includes the length of the string plus the length of the null terminator but does not include the length of the length field itself.

The parameter type-checking strings contain binary values and are not null-terminated. The value in the length field includes the length of the string only but does not include the length of the length field itself.

The symbol table entries of the loader section contain a byte offset value that points to the first byte of the string instead of to the length field.

## Loader Section Header Contents

The contents of the section header fields for the loader section are:

| Name      | Contents                                                                                 |
|-----------|------------------------------------------------------------------------------------------|
| s_name    | .loader                                                                                  |
| s_paddr   | 0                                                                                        |
| s_vaddr   | 0                                                                                        |
| s_size    | The size (in bytes) of the loader section                                                |
| s_scnptr  | Offset from the beginning of the XCOFF file to the first byte of the loader section data |
| s_relptra | 0                                                                                        |
| s_lnnoptr | 0                                                                                        |
| s_nreloc  | 0                                                                                        |
| s_nlnno   | 0                                                                                        |
| s_flags   | STYP_LOADER                                                                              |

For general information on the XCOFF file format, see "XCOFF Object File Format."

For more information on XCOFF file sections, see "Sections and Section Headers," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Debug Section

The debug section contains the symbolic debugger stabstrings (symbol table strings). It is generated by the compilers and assemblers. It provides symbol attribute information for use by the symbolic debugger. The debug section has a section type flag of **STYP\_DEBUG** in the XCOFF section header. By convention, .debug is the debug section name. The data in this section is referenced from entries in the XCOFF symbol table. A stabstring is a null-terminated character string. Each string is preceded by a 2-byte length field in XCOFF32 or a 4-byte length field in XCOFF64.

### Field Definitions

The following two fields are repeated for each symbolic debugger stabstring:

- A 2-byte (XCOFF32) or 4-byte (XCOFF64) length field containing the length of the string. The value contained in the length field includes the length of the terminating null character but does not include the length of the length field itself.
- The symbolic debugger stabstring.

Refer to discussion of symbolic debugger stabstring grammar for the specific format of the stabstrings.

## Debug Section Header Contents

The contents of the section header fields for the debug section are:

| Name      | Contents                                                                                |
|-----------|-----------------------------------------------------------------------------------------|
| s_name    | .debug                                                                                  |
| s_paddr   | 0                                                                                       |
| s_vaddr   | 0                                                                                       |
| s_size    | The size (in bytes) of the debug section                                                |
| s_scnptr  | Offset from the beginning of the XCOFF file to the first byte of the debug section data |
| s_relptra | 0                                                                                       |
| s_lnnoptr | 0                                                                                       |
| s_nreloc  | 0                                                                                       |
| s_nlnno   | 0                                                                                       |
| s_flags   | STYP_DEBUG                                                                              |

For general information on the **XCOFF** file format, see "XCOFF Object File Format."

For more information on **XCOFF** file sections, see "Sections and Section Headers," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Type-Check Section

The type-check section contains the type-checking hash strings and is produced by compilers and assemblers. It is used by the binder to detect variable mismatches and argument interface errors when linking separately compiled object files. (The type-checking hash strings in the loader section are used to detect these errors prior to running a program.) The type-check section has a section type flag of **STYP\_TYPCHK** in the **XCOFF** section header. By convention, **.typchk** is the type-check section name. The strings in this section are referenced from entries in the **XCOFF** symbol table.

### Field Definitions

The following two fields are repeated for each parameter type-checking string:

- A 2-byte length field containing the length of the type-checking string. The value contained in the length field does not include the length of the length field itself.
- The parameter type-checking hash string.

### Type Encoding and Checking Format for Data

The type-checking hash strings are used to detect errors prior to execution of a program. Information about all external symbols (data and functions) is encoded by the compilers and then checked for consistency at bind time and load time. The type-checking strings are designed to enforce the maximum checking required by the semantics of each particular language supported, as well as provide protection to applications written in more than one language.

The type encoding and checking mechanism features 4-part hash encoding that provides some flexibility in checking. The mechanism also uses a unique value, **UNIVERSAL**, that matches any code. The **UNIVERSAL** hash can be used as an escape mechanism for assembly programs or for programs in which type information or subroutine interfaces might not be known. The **UNIVERSAL** hash is four blank ASCII characters (0x20202020) or four null characters (0x00000000).

The following fields are associated with the type encoding and checking mechanism:

| Item                | Description                                                                                                                                                                                                                                                                                                                                |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| code length         | A 2-byte field containing the length of the hash. This field has a value of 10.                                                                                                                                                                                                                                                            |
| language identifier | A 2-byte code representing each language. These codes are the same as those defined for the <b>e_lang</b> field in the "Exception Section" information .                                                                                                                                                                                   |
| general hash        | A 4-byte field representing the most general form by which a data symbol or function can be described. This form is the most common to languages supported by . If the information is incomplete or unavailable, a universal hash should be generated. The general hash is language-independent and must match for the binding to succeed. |
| language hash       | A 4-byte field containing a more detailed, language-specific representation of what is in the general hash. It allows for the strictest type-checking required by a given language. This part is used in intra-language binding and is not checked unless both symbols have the same language identifier.                                  |

### Section Header Contents

The contents of the section header fields for the type-check section are:

| Name      | Contents                                                                                     |
|-----------|----------------------------------------------------------------------------------------------|
| s_name    | .typchk                                                                                      |
| s_paddr   | 0                                                                                            |
| s_vaddr   | 0                                                                                            |
| s_size    | The size (in bytes) of the type-check section                                                |
| s_scnptr  | Offset from the beginning of the XCOFF file to the first byte of the type-check section data |
| s_relptr  | 0                                                                                            |
| s_lnnoptr | 0                                                                                            |
| s_nreloc  | 0                                                                                            |
| s_nlnno   | 0                                                                                            |
| s_flags   | STYP_TYPCHK.                                                                                 |

For general information on the **XCOFF** file format, see "XCOFF Object File Format."

For more information on **XCOFF** file sections, see "Sections and Section Headers," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Exception Section

The exception section contains addresses of trap instructions, source language identification codes, and trap reason codes. This section is produced by compilers and assemblers, and used during or after run time to identify the reason that a specific trap or exception occurred. The exception section has a section type flag of **STYP\_EXCEPT** in the XCOFF section header. By convention, .except is the exception section name. Data in the exception section is referenced from entries in the XCOFF symbol table.

An exception table entry with a value of 0 in the e\_reason field contains the symbol table index to a function's **C\_EXT**, **C\_WEAKEXT**, or **C\_HIDEEXT** symbol table entry. Reference from the symbol table to an entry in the exception table is via the function auxiliary symbol table entry. For more information on this entry, see "csect Auxiliary Entry for **C\_EXT**, **C\_WEAKEXT** and **C\_HIDEEXT** Symbols."

The C language structure for the exception section entries can be found in the **exceptab.h** file.

The exception section entries contain the fields shown in the following tables.

*Table 21. Initial Entry: Exception Section Structure*

| Field Name and Description                                      | XCOFF32                                                                            | XCOFF64                                                                            |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| e_addr.e_symndx <sup>+</sup><br>Symbol table index for function | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> |
| e_lang <sup>+</sup> Compiler language ID code                   | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 1</li> </ul> |
| e_reason <sup>+</sup><br>Value 0 (exception reason code 0)      | <ul style="list-style-type: none"> <li>• Offset: 5</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 9</li> <li>• Length: 1</li> </ul> |

**Note:** +Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined. With e\_addr.e\_symndx, the suffix is added to e\_addr (i.e. e\_addr32.e\_symndx).

*Table 22. Subsequent Entry: Exception Section Structure*

| Field Name and Description                                           | XCOFF32                                                                            | XCOFF64                                                                            |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>e_addr.e_paddr<sup>+</sup></b><br>Address of the trap instruction | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul> |
| <b>e_lang<sup>+</sup></b> Compiler language ID code                  | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 1</li> </ul> |
| <b>e_reason<sup>+</sup></b><br>Trap exception reason code            | <ul style="list-style-type: none"> <li>• Offset: 5</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 9</li> <li>• Length: 1</li> </ul> |

**Note:** +Use "32" or "64" suffix when XCOFF\_HYBRID is defined. With e\_addr.e\_paddr, the suffix is added to e\_addr (i.e. e\_addr32.e\_paddr).

## Field Definitions

The following defines the fields listed of the exception section:

| Item            | Description                                                                                                                                                                                     |           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| <u>e_symndx</u> | Contains an integer (overlays the <u>e_paddr</u> field). When the <u>e_reason</u> field is 0, this field is the symbol table index of the function.                                             |           |
| <u>e_paddr</u>  | Contains a virtual address (overlays the <u>e_symndx</u> field). When the <u>e_reason</u> field is nonzero, this field is the virtual address of the trap instruction.                          |           |
| <u>e_lang</u>   | Specifies the source language. The following list defines the possible values of the <u>e_lang</u> field.                                                                                       |           |
|                 | <b>ID</b>                                                                                                                                                                                       | Language  |
|                 | 0x00                                                                                                                                                                                            | C         |
|                 | 0x01                                                                                                                                                                                            | FORTRAN   |
|                 | 0x02                                                                                                                                                                                            | Pascal    |
|                 | 0x03                                                                                                                                                                                            | Ada       |
|                 | 0x04                                                                                                                                                                                            | PL/I      |
|                 | 0x05                                                                                                                                                                                            | BASIC     |
|                 | 0x06                                                                                                                                                                                            | Lisp      |
|                 | 0x07                                                                                                                                                                                            | COBOL     |
|                 | 0x08                                                                                                                                                                                            | Modula2   |
|                 | 0x09                                                                                                                                                                                            | C++       |
|                 | 0x0A                                                                                                                                                                                            | RPG       |
|                 | 0x0B                                                                                                                                                                                            | PL8, PLIX |
|                 | 0x0C                                                                                                                                                                                            | Assembly  |
|                 | 0x0D-0xFF                                                                                                                                                                                       | Reserved  |
| <u>e_reason</u> | Specifies an 8-bit, compiler-dependent trap exception reason code. Zero is not a valid trap exception reason code because it indicates the start of exception table entries for a new function. |           |

## Section Header Contents

The following fields are the contents of the section header fields for the exception section.

| Name      | Contents                                                                                    |
|-----------|---------------------------------------------------------------------------------------------|
| s_name    | .except                                                                                     |
| s_paddr   | 0                                                                                           |
| s_vaddr   | 0                                                                                           |
| s_size    | The size (in bytes) of the exception section                                                |
| s_scnptr  | Offset from the beginning of the XCOFF file to the first byte of the exception section data |
| s_relptr  | 0                                                                                           |
| s_lnnoptr | 0                                                                                           |
| s_nreloc  | 0                                                                                           |
| s_nlnno   | 0                                                                                           |
| s_flags   | STYP_EXCEPT                                                                                 |

For general information on the XCOFF file format, see "XCOFF Object File Format."

For more information on XCOFF file sections, see "Sections and Section Headers," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Comment Section

The comment section contains information of special processing significance to an application. This section can be produced by compilers and assemblers and used during or after run time to fulfill a special processing need of an application. The comment section has a section type flag of STYP\_INFO in the XCOFF section header. By convention, .info is the comment section name. Data in the comment section is referenced from C\_INFO entries in the XCOFF symbol table.

The contents of a comment section consists of repeated instances of a 4-byte length field followed by a string of bytes (containing any binary value). The length of each string is stored in its preceding 4-byte length field. The string of bytes need not be terminated by a null character nor by any other special character. The specified length does not include the length of the length field itself. A length of 0 is allowed. The format of the string of bytes is not specified.

A comment section string is referenced from an entry in the XCOFF symbol table. The storage class of the symbol making a reference is C\_INFO. See "Symbol Table Field Contents by Storage Class" for more information.

A C\_INFO symbol is associated with the nearest C\_FILE, C\_EXT, C\_WEAKEXT, or C\_HIDEEXT symbol preceding it.

## Section Header Contents

The following fields are the contents of the section header fields for the comment section.

| Name      | Contents                                                                                  |
|-----------|-------------------------------------------------------------------------------------------|
| s_name    | .info                                                                                     |
| s_paddr   | 0                                                                                         |
| s_vaddr   | 0                                                                                         |
| s_size    | The size (in bytes) of the comment section                                                |
| s_scnptr  | Offset from the beginning of the XCOFF file to the first byte of the comment section data |
| s_relptr  | 0                                                                                         |
| s_lnnoptr | 0                                                                                         |
| s_nreloc  | 0                                                                                         |
| s_nlnno   | 0                                                                                         |
| s_flags   | STYP_INFO                                                                                 |

For general information on the XCOFF file format, see "XCOFF Object File Format."

For more information on XCOFF file sections, see "Sections and Section Headers," "Debug Section," "Type-Check Section," "Exception Section," and "Comment Section."

## Relocation Information for XCOFF File (reloc.h)

The .text section and .data section may have relocation information. The binder uses the relocation information to modify the .text section and .data section contents with address and byte-offset information of individual XCOFF object files collected into an XCOFF executable file.

The compilers and assemblers generate the relocation entries for the .text and .data sections.

The binder generates relocation information for the .loader section, as required by the system loader.

Each relocation entry of the .text and .data section is 10 bytes long (14 for XCOFF64). (A relocation entry in the .loader section is 12 bytes long (16 for XCOFF64) and is explained in the loader section description in this document. See "Relocation Table Field Definitions" for more information.) You can find the C language structure for a relocation entry in the **reloc.h** file. A relocation entry contains the fields shown in the following table.

*Table 23. Relocation Entry Structure*

| Field Name and Description                                                           | XCOFF32                                                                     | XCOFF64                                                                      |
|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|------------------------------------------------------------------------------|

| <b>r_rsize</b> <sup>+</sup><br>Relocation size and information                       | <ul style="list-style-type: none"><li>Offset: 8</li><li>Length: 1</li></ul> | <ul style="list-style-type: none"><li>Offset: 12</li><li>Length: 1</li></ul> |
| <b>r_rtype</b> <sup>+</sup><br>Relocation type                                       | <ul style="list-style-type: none"><li>Offset: 9</li><li>Length: 1</li></ul> | <ul style="list-style-type: none"><li>Offset: 13</li><li>Length: 1</li></ul> |

**Note:** +Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.+Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined.

The relocation entries for the .text and .data sections are part of their respective sections. The relocation entry refers to a location to be modified. The relocation entries for a section must be in ascending address order.

(The loader section contains a single set of relocation entries used by the system loader; so a section number is required within each relocation entry to identify the section that needs to be modified.)

### Field Definitions

The following defines the relocation-information fields:

| Item     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| r_vaddr  | Specifies the virtual address of the value that requires modification by the binder. The byte offset value to the data that requires modification from the beginning of the section that contains the data can be calculated as follows:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| r_symndx | <pre>offset_in_section = r_vaddr - s_paddr</pre> <p>Specifies a zero-based index into the XCOFF symbol table for locating the referenced symbol. The symbol table entry contains an address used to calculate a modification value to be applied at the r_vaddr relocation address.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| r_rsize  | Specifies the relocation size and sign. Its contents are detailed in the following list:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|          | <b>0x80 (1 bit)</b><br>Indicates whether the relocation reference is signed (1) or unsigned (0).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|          | <b>0x40 (1 bit)</b><br>If this field is one, it indicates that the binder replaced the original instruction by a branch instruction to a special fixup instruction sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|          | <b>0x3F(6 bits)</b><br>Specifies the bit length of the relocatable reference minus one. The current architecture allows for fields of up to 32 bits (XCOFF32) or 64 bits (XCOFF64) to be relocated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| r_rtype  | Specifies an 8-bit relocation type field that indicates to the binder which relocation algorithm to use for calculating the modification value. This value is applied at the relocatable reference location specified by the r_vaddr field. The following relocation types are defined:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0x00     | R_POS<br>Specifies positive relocation. Provides the address of the symbol specified by the r_symndx field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0x01     | R_NEG<br>Specifies negative relocation. Provides the negative of the address of the symbol specified by the r_symndx field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0x02     | R_REL<br>Specifies relative-to-self relocation. Provides a displacement value between the address of the symbol specified by the r_symndx field and the address of the csect to be modified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0x03     | R_TOC<br>Specifies a relocation that is relative to TOC. Provides a displacement value that is the difference between the address value in the symbol specified by the r_symndx field and the address of the TOC anchor csect. The TOC anchor csect is a symbol with storage-mapping class defined as XMC_TC0 and with a length of 0. At most, one TOC anchor csect is allowed per XCOFF section.<br><br>A link editor is allowed to transform the instruction referenced by the r_vaddr field. The symbol specified by the r_symndx field is a TOC symbol if its storage-mapping class is XMC_TC, and the TOC symbol contains the address of another symbol that is within 32,768 bytes of the TOC anchor or the thread-local storage base. Therefore, if the referenced instruction is a load, and the symbol specified by the r_symndx field is a TOC symbol, the load can be converted into an add-immediate instruction. This transformation eliminates a storage reference during execution. If the instruction is transformed, the R_TOC relocation type is replaced by a R_TRLA relocation type when the output file is written. This enables a reverse transformation if the object is re-linked. |
| 0x04     | R_TRL<br>Specifies a relocation that is relative to TOC. This relocation entry is treated the same as an R_TOC relocation entry, except that link editors are not allowed to convert the instruction from a load to an add-immediate instruction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0x13     | R_TRLA<br>Specifies a relocation that is either relative to TOC or relative to the thread-local storage base. The instruction specified by the r_vaddr field is an add-immediate instruction, and the symbol specified by the r_symndx field must be a TOC symbol, which means that its storage-mapping class is XMC_TC. This instruction is previously transformed by a link editor from a load instruction into an add-immediate instruction. The link editor transforms the instruction back into a load instruction, and changes the relocation type from R_TRLA to R_TOC. The instruction can be transformed again as described for the R_TOC relocation entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                   | Specifies local object TOC address relocation. Provides the address of the TOC associated with a defined external symbol. The external symbol for which the TOC address is required is specified by the r_symndx field of the relocation entry. The external symbol is defined locally within the resultant executable. This relocation entry provides a method of accessing the address of the TOC contained within the same executable where the r_symndx external symbol is defined. |

|                   | Specifies a nonrelocating reference to prevent garbage collection (by the binder) of a symbol. This relocation type is intended to provide compilers and assemblers a method to specify that a given csect has a dependency upon another csect without using any space in the actual csect. The reason for making the dependency reference is to prevent the binder from garbage-collecting (eliminating) a csect for which another csect has an implicit dependency.                   |

|                   | Specifies branch absolute relocation. Provides the address of the symbol specified by the r_symndx field as the target address of a branch instruction. The instruction can be modified to a (relative) branch instruction if the target address is relocatable.                                                                                                                                                                                                                        |
| <b>0x0A</b>       | <b>R_BR</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                   | Treated the same as the <b>R_RBR</b> relocation type.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>0x1A</b>       | <b>R_RBR</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|                   | Specifies (relative) branch relocation. Provides a displacement value between the address of the symbol specified by the r_symndx field and the address of the csect containing the branch instruction to be modified. The instruction can be modified to an absolute branch instruction if the target address is not relocatable.                                                                                                                                                      |
|                   | The <b>R_RBR</b> relocation type is the standard branch relocation type used by compilers and assemblers for the . This relocation type along with glink code allows an executable object file to have a text section that is position-independent.                                                                                                                                                                                                                                     |

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| r_type continued |                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0x20 R_TLS       | Specifies thread-local storage relocation, using the general-dynamic model. Provides an offset into the thread-local storage for the module.                                                                                                                                                                                                                                                                                                                           |
| 0x21 R_TLS_IE    | Same as <b>R_TLS</b> , except that the initial-exec model is used. That is, the referenced symbol must be exported by the main program or a module that is loaded at exec time.                                                                                                                                                                                                                                                                                        |
| 0x22 R_TLS_LD    | Same as <b>R_TLS</b> , except that the local-dynamic model is used. That is, the referenced symbol must be in the referencing module.                                                                                                                                                                                                                                                                                                                                  |
| 0x23 R_TLS_LE    | Same as <b>R_TLS</b> , except that local-exec model is used. That is, both the reference and the referenced symbol must be in the main program.                                                                                                                                                                                                                                                                                                                        |
| 0x24 R_TLSM      | Specifies thread-local storage relocation. Provides a handle for the thread-local storage of the referenced variable. The handle is used by the pthread runtime to locate the thread-local storage.                                                                                                                                                                                                                                                                    |
| 0x25 R_TLSML     | Specifies thread-local storage relocation. Provides a handle for the module containing the reference. The <b>r_symndx</b> field must specify the symbol table index of the csect symbol containing the reference.                                                                                                                                                                                                                                                      |
| 0x30 R_TOCU      | Specifies the high-order 16 bits of a TOC-relative relocation. Similar to the <b>R_TOC</b> relocation, a displacement value is computed. The displacement value is the difference between the address value in the symbol that the <b>r_symndx</b> field specifies and the address of the TOC anchor csect. The high-order 16 bits of the displacement are used to update the instruction. This relocation can overflow if the TOC size is larger than $2^{31}$ bytes. |
| 0x31 R_TOCL      | Specifies the low-order 16 bits of a TOC-relative relocation. Similar to the <b>R_TOC</b> relocation, a displacement value is computed. The displacement value is the difference between the address value in the symbol that the <b>r_symndx</b> field specifies and the address of the TOC anchor csect. The low-order 16 bits of the displacement are used to update the instruction.                                                                               |

## Additional Relocation Features

Standard practice is to retain relocation information only for unresolved references or references between distinct sections. Once a reference is resolved, the relocation information is discarded. This is sufficient for an incremental bind and a fixed address space model. To provide the capability for rebinding and handling a relocatable address space model, the relocation information is not discarded from an **XCOFF** file.

For general information on the **XCOFF** file format, see "XCOFF Object File Format."

For more information on relocation field table definitions, see "Relocation Table Field Definitions" in the loader section.

## Line Number Information for XCOFF File (linenum.h)

Line number entries are used by the symbolic debugger to debug code at the source level. When present, there is a single line number entry for every source line that can have a symbolic debugger breakpoint. The line numbers are grouped by function. The beginning of each function is identified by the **l\_lno** field containing a value of 0. The first field, **l\_symndx**, is the symbol table index to the **C\_EXT**, **C\_WEAKEXT**, or **C\_HIDEEXT** symbol table entry for the function.

Each line number entry is six bytes long. The C language structure for a line number entry can be found in the **linenum.h** file. A line number entry contains the fields shown in the following tables.

*Table 24. Initial Line Number Structure Entry for Function*

| Field Name and Description                                            | XCOFF32                                                                            | XCOFF64                                                                            |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>l_addr.l_symndx<sup>+</sup></b><br>Symbol table index for function | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> |
| <b>l_lino<sup>+</sup></b><br>Value 0 (line number 0)                  | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul> |

**Note:** +Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined. With **l\_addr.l\_symndx**, the suffix is added to **l\_addr** (i.e. **l\_addr32.l\_symndx**).

*Table 25. Subsequent Line Number Entries for Function*

| Field Name and Description                                                 | XCOFF32                                                                            | XCOFF64                                                                            |
|----------------------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>l_paddr<sup>+</sup></b><br>Address at which break point can be inserted | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul> |
| <b>l_lino<sup>+</sup></b><br>Line number relative to start of function     | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul> |

**Note:** +Use "32" or "64" suffix when **\_XCOFF\_HYBRID\_** is defined. With **l\_addr.l\_paddr**, the suffix is added to **l\_addr** (i.e. **l\_addr32.l\_paddr**).

## Field Definitions

The following list defines the line number entries:

| Item            | Description                                                                                                                                                                                                               |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>l_symndx</b> | Specifies the symbol table index to the function name (overlays the <b>l_paddr</b> field). When the <b>l_lino</b> field is 0, this interpretation of the field is used.                                                   |
| <b>l_paddr</b>  | Specifies the virtual address of the first instruction of the code associated with the line number (overlays the <b>l_symndx</b> field). When the <b>l_lino</b> field is not 0, this interpretation of the field is used. |
| <b>l_lino</b>   | Specifies either the line number relative to the start of a function or 0 to indicate the beginning of a function.                                                                                                        |

**Note:** If part of a function other than the beginning comes from an include file, the line numbers are absolute, rather than relative to the beginning of the function. (See the **C\_BINCL** and **C\_EINCL** symbol types in "Storage Classes by Usage and Symbol Value Classification" for more information.)

For general information on the XCOFF file format, see "XCOFF Object File Format."

For information on debugging, see "Debug Section."

## Symbol Table Information

One composite symbol table is defined for an XCOFF file. The symbol table contains information required by both the binder (external symbols) and the symbolic debugger (function definitions and internal and external symbols).

The symbol table consists of a list of 18-byte, fixed-length entries. Each symbol represented in the symbol table consists of at least one fixed-length entry, and some are followed by auxiliary entries of the same size.

See the following information to learn more about the symbol table:

- Symbol Table Auxiliary Information
- Symbol Table Field Contents by Storage Class
- String Table

For each external symbol, one or more auxiliary entries are required that provide additional information concerning the external symbol. There are three major types of external symbols of interest to the binder, performing the following functions:

- Define replaceable units or csects.
- Define the external names for functions or entry points within csects.
- Reference the names of external functions in another XCOFF object.

For symbols defining a replaceable unit (csect), a csect auxiliary entry defines the length and storage-mapping class of the csect. For symbols defining external names for functions within a csect, the csect auxiliary entry points to the containing csect, the parameter type-checking information, and the symbolic debugger information for the function. For symbols referencing the name of an external function, a csect auxiliary entry identifies the symbol as an external reference and points to parameter type-checking information.

## Symbol Table Contents

An XCOFF symbol table has the following general contents and ordering:

- The **C\_FILE** symbol table entries used to bracket all the symbol table entries associated with a given source file.
- The **C\_INFO** comment section symbol table entries that are of source file scope. These follow the **C\_FILE** entry but before the first csect definition symbol table entry.
- The symbolic debugger symbol table entries that are of file scope. These follow the **C\_FILE** entry but before the first csect entry.
- csect definition symbol table entries used to define and bracket all the symbols contained with a csect.
- **C\_INFO** comment section symbol table entries that follow a csect definition symbol table entry are associated with that csect.
- All symbolic debugger symbol table entries that follow a csect definition symbol table entry or label symbol table entry are associated with that csect or label.

The ordering of the symbol table must be arranged by the compilers and assemblers both to accommodate the symbolic debugger requirements and to permit effective management by the binder of the different sections of the object file as a result of such binder actions as garbage collection, incremental binding, and rebinding. This ordering is required by the binder so that if a csect is deleted or replaced, all the symbol table information associated with the csect can also be deleted or replaced. Likewise, if all the csects associated with a source file are deleted or replaced, all the symbol table and related information associated with the file can also be deleted or replaced.

## Symbol Table Layout

The following example shows the general ordering of the symbol table.

```
un_external Undefined global symbols .file Prolog --defines stabstring compaction level .file Source file 1
.info Comment section reference symbol with file scope stab Global Debug symbols of a file csect
Replaceable unit definition (code) .info Comment section reference symbol with csect scope function
Local/External function stab Debug and local symbols of function function Local/External function stab
Debug and local symbols of function csect Replaceable unit definition (local statics) stab Debug
and local statics of file csect Relocatable unit definition (global data) external Defined global
symbol stab Debug info for global symbolfile Source file 2 stab Global Debug symbols of a file
```

csect Replaceable unit definition (code) function Local/External function stab Debug and local symbols of function ..... csect Replaceable unit definition (local statics) stab Debug and Local statics of file ..... csect Replaceable unit definition (global data) external Defined global symbol stab Debug info for global symbol .file Source file .....

### Symbol Table Entry (syms.h)

Each symbol, regardless of storage class and type, has a fixed-format entry in the symbol table. In addition, some symbol types may have additional (auxiliary) symbol table entries immediately following the fixed-format entry. Each entry in the symbol table is 18 bytes long. The C language structure for a symbol table entry can be found in the **syms.h** file. The index for the first entry in the symbol table is 0. The following table shows the structure of the fixed-format part of each symbol in the symbol table.

*Table 26. Symbol Table Entry Format*

| Field Name and Description                                                                                                              | XCOFF32                                                                             | XCOFF64                                                                                |
|-----------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| <b>n_name</b> Symbol name (occupies the same 8 bytes as <b>n_zeroes</b> and <b>n_offset</b> )                                           | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> |
| <b>n_zeroes</b> Zero, indicating name in string table or .debug section (overlays first 4 bytes of <b>n_name</b> )                      | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> |
| <b>n_offset</b> <sup>+</sup> Offset of the name in string table or .debug section (In XCOFF32: overlays last 4 bytes of <b>n_name</b> ) | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul>     |
| <b>n_value</b> <sup>+</sup> Symbol value; storage class-dependent                                                                       | <ul style="list-style-type: none"> <li>• Offset: 8</li> <li>• Length: 4</li> </ul>  | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 8</li> </ul>     |
| <b>n_scnum</b> Section number of symbol                                                                                                 | <ul style="list-style-type: none"> <li>• Offset: 12</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 12</li> <li>• Length: 2</li> </ul>    |
| <b>n_type</b> Basic and derived type specification                                                                                      | <ul style="list-style-type: none"> <li>• Offset: 14</li> <li>• Length: 2</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 14</li> <li>• Length: 2</li> </ul>    |
| <b>n_lang</b> Source language ID (overlays first byte of <b>n_type</b> )                                                                | <ul style="list-style-type: none"> <li>• Offset: 14</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 14</li> <li>• Length: 1</li> </ul>    |
| <b>n_cpu</b> CPU Type ID (overlays second byte of <b>n_type</b> )                                                                       | <ul style="list-style-type: none"> <li>• Offset: 15</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 15</li> <li>• Length: 1</li> </ul>    |
| <b>n_sclass</b> Storage class of symbol                                                                                                 | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 16</li> <li>• Length: 1</li> </ul>    |
| <b>n_numaux</b> Number of auxiliary entries                                                                                             | <ul style="list-style-type: none"> <li>• Offset: 17</li> <li>• Length: 1</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 17</li> <li>• Length: 1</li> </ul>    |

**Note:** +Use "32" or "64" suffix when **\_\_XCOFF\_HYBRID\_\_** is defined.

### Field Definitions

The following defines the symbol table entry fields:

| Item                           | Description                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n_name                         | Used by XCOFF32 only. Specifies an 8-byte, null-padded symbol name or symbolic debugger stabstring. The storage class field is used to determine if the field is a symbol name or symbolic debugger stabstring. By convention, a storage class value with the high-order bit on indicates that this field is a symbolic debugger stabstring. |
|                                | If the XCOFF32 symbol name is longer than 8 bytes, the field is interpreted as the following two fields:                                                                                                                                                                                                                                     |
| n_zeroes                       | A value of 0 indicates that the symbol name is in the string table or .debug section (overlays first word of n_name).                                                                                                                                                                                                                        |
| n_offset                       | Specifies the byte offset to the symbol name in the string table or .debug section (overlays last 4 bytes of n_name). The byte offset is relative to the start of the string table or .debug section. A byte offset value of 0 is a null or zero-length symbol name.                                                                         |
| n_offset                       | For XCOFF64: Specifies the byte offset to the symbol name in the string table or .debug section. The byte offset is relative to the start of the string table or .debug section. A byte offset value of 0 is a null or zero-length symbol name. (For XCOFF32 only, used in conjunction with n_zeroes. See entry immediately above.)          |
| n_value                        | Specifies the symbol value. The contents of the symbol value field is storage class-dependent, as shown in the following definitions:                                                                                                                                                                                                        |
| Content Storage Class          |                                                                                                                                                                                                                                                                                                                                              |
| Relocatable address            | C_EXT, C_WEAKEXT, C_HIDEEXT, C_FCN, C_BLOCK, C_STAT                                                                                                                                                                                                                                                                                          |
| Zero                           | C_GSYM, C_BCOMM, C_DECL, C_ENTRY, C_ESTAT, C_ECOMM                                                                                                                                                                                                                                                                                           |
| Offset in csect                | C_FUN, C_STSYM                                                                                                                                                                                                                                                                                                                               |
| Offset in file                 | C_BINCL, C_EINCL                                                                                                                                                                                                                                                                                                                             |

| Register number                | C_RPSYM, C_RSYM                                                                                                                                                                                                                                                                                                                              |
| Offset within common block     | C_ECOML                                                                                                                                                                                                                                                                                                                                      |
| n_scnum                        | Specifies a section number associated with one of the following symbols:                                                                                                                                                                                                                                                                     |
| -2                             | Specifies N_DEBUG, a special symbolic debugging symbol.                                                                                                                                                                                                                                                                                      |
| -1                             | Specifies N_ABS, an absolute symbol. The symbol has a value but is not relocatable.                                                                                                                                                                                                                                                          |
| 0                              | Specifies N_UNDEF, an undefined external symbol.                                                                                                                                                                                                                                                                                             |
| Any other value                | Specifies the section number where the symbol was defined.                                                                                                                                                                                                                                                                                   |

| Item            | Description                                                                                                                                                                                                                                                                                           |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| n_type          | The use of this field depends on the storage class of the symbol. For C_FILE symbols, see "File Auxiliary Entry for the C_FILE Symbol".                                                                                                                                                               |
|                 | For the C_EXT, C_HIDEEXT, and C_WEAKEXT symbols, the n_type field has two interpretations in XCOFF32, and a single interpretation in XCOFF64. The old interpretation is used in XCOFF32 if the value of the o_vstamp field in the auxiliary header is 1.                                              |
|                 | In the old XCOFF32 interpretation, bit 10 (0x0020) can be set if the symbol is a function. Otherwise, bit 10 should be 0. The remaining bits are defined in COFF file to represent type information and are no longer used.                                                                           |
|                 | In XCOFF64 and the new XCOFF32 interpretation, the n_type field is used for the symbol type and visibility as follows:                                                                                                                                                                                |
| Bits 0-3        | Symbol visibility. The SYM_V_MASK macro, with the value 0xF000, can be used to mask off bits in the n_type field that do not specify visibility. The following visibilities are defined:                                                                                                              |
|                 | 0x1000 SYM_V_INTERNAL<br>0x2000 SYM_V_HIDDEN<br>0x3000 SYM_V_PROTECTED<br>0x4000 SYM_V_EXPORTED                                                                                                                                                                                                       |
| Bit 10          | Optionally set to 1 if the symbol is a function. Otherwise, it is set to 0.                                                                                                                                                                                                                           |
| Bits 4-9, 11-15 | Reserved for future use.                                                                                                                                                                                                                                                                              |
| n_sclass        | Symbol visibility is described in the <b>ld</b> command.<br><b>Note:</b> For all other storage classes, the n_type field is reserved for future use and should contain 0.                                                                                                                             |
| n_numaux        | Specifies the storage class of the symbol. The <b>storclass.h</b> and <b>dbxstclass.h</b> files contain the definitions of the storage classes. See "Symbol Table Field Contents by Storage Class" for more information.                                                                              |
|                 | Specifies the number of auxiliary entries for the symbol. In XCOFF64, auxiliary symbols have an identifying type field, but in XCOFF32, there is no type field. Therefore, if more than one auxiliary entry is required for a symbol, the order of the auxiliary entries is determined by convention. |

For general information on the XCOFF file format, see "XCOFF Object File Format."

## Symbol Table Auxiliary Information

The symbol table contains auxiliary entries to provide supplemental information for a symbol. The auxiliary entries for a symbol follow its symbol table entry. The length of each auxiliary entry is the same as a symbol table entry (18 bytes). The format and quantity of auxiliary entries depend on the storage class (n\_sclass) and type (n\_type) of the symbol table entry.

In XCOFF32, symbols having a storage class of C\_EXT, C\_WEAKEXT or C\_HIDEEXT and more than one auxiliary entry must have the csect auxiliary entry as the last auxiliary entry. In XCOFF64, the x\_auxtype field of each auxiliary symbol table entry differentiates the symbols, but the convention is to generate the csect auxiliary symbol table entry last.

### File Auxiliary Entry for C\_FILE Symbols

The file auxiliary symbol table entry is defined to contain the source file name and compiler-related strings. A file auxiliary entry is optional and is used with a symbol table entry that has a storage-class value of C\_FILE. The C language structure for a file auxiliary entry can be found in the x\_file structure in the **syms.h** file.

The C\_FILE symbol provides source file-name information, source-language ID and CPU-version ID information, and, optionally, compiler-version and time-stamp information.

The n\_type field of the symbol table entry identifies the source language of the source file and the CPU version ID of the compiled object file. The field information is as follows:

| <b>Item</b>        | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |          |           |          |                          |          |           |          |                                                            |          |                      |          |                                                                    |          |                                          |              |           |            |                         |                |           |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-----------|----------|--------------------------|----------|-----------|----------|------------------------------------------------------------|----------|----------------------|----------|--------------------------------------------------------------------|----------|------------------------------------------|--------------|-----------|------------|-------------------------|----------------|-----------|
| Source Language ID | <p>Overlays the high-order byte of the <code>n_type</code> field. This field contains the source-language identifier. The values for this field are defined in the <code>e_lang</code> field in "Exception Section". This field can be used by the symbolic debuggers to determine the source language.</p> <p>The optional values for this field are 248 (TB_OBJECT) for symbols from object files with no <code>C_FILE</code> symbol table entry; or 249 (TB_FRONT) or 250 (TB_BACK) for generated entries used to provide debugging information. If the source language is TB_FRONT or TB_BACK, the 8-character name field begins with ' ' (blank), '\0'(NULL). If the source language is TB_FRONT, the third byte is the stabstring compaction level for the object file, and the <code>n_offset</code> field contains the symbol table index of the TB_BACK symbol table entry, if it exists, or 0 otherwise.</p> |          |           |          |                          |          |           |          |                                                            |          |                      |          |                                                                    |          |                                          |              |           |            |                         |                |           |
| CPU Version ID     | <p>Defined as the low-order byte of the <code>n_type</code> field. Describes the kind of instructions generated for the file. The following values are defined:</p> <table style="margin-left: 20px;"> <tr><td><b>0</b></td><td>Reserved.</td></tr> <tr><td><b>1</b></td><td>Specifies , 32-bit mode.</td></tr> <tr><td><b>2</b></td><td>Reserved.</td></tr> <tr><td><b>3</b></td><td>Specifies the common intersection of 32-bit and Processor.</td></tr> <tr><td><b>4</b></td><td>Specifies Processor.</td></tr> <tr><td><b>5</b></td><td>Specifies any mix of instructions between different architectures.</td></tr> <tr><td><b>6</b></td><td>Specifies a mix of and instructions () .</td></tr> <tr><td><b>7-223</b></td><td>Reserved.</td></tr> <tr><td><b>224</b></td><td>Specifies instructions.</td></tr> <tr><td><b>225-255</b></td><td>Reserved.</td></tr> </table>                                         | <b>0</b> | Reserved. | <b>1</b> | Specifies , 32-bit mode. | <b>2</b> | Reserved. | <b>3</b> | Specifies the common intersection of 32-bit and Processor. | <b>4</b> | Specifies Processor. | <b>5</b> | Specifies any mix of instructions between different architectures. | <b>6</b> | Specifies a mix of and instructions () . | <b>7-223</b> | Reserved. | <b>224</b> | Specifies instructions. | <b>225-255</b> | Reserved. |

| <b>x_fname</b>   | Source file string |                                                                                                |
| <b>0</b>         | 4                  |                                                                                                |
| <b>x_zeroes</b>  |                    | Zero, indicating file string in string table (overlays first 4 bytes of <code>x_fname</code> ) |
| <b>4</b>         | 4                  |                                                                                                |
| <b>x_offset</b>  |                    | Offset of file string in string table (overlays 5th-8th bytes of <code>x_fname</code> )        |
| <b>14</b>        | 1                  |                                                                                                |
| <b>x_ftype</b>   | File string type   |                                                                                                |
| <b>15</b>        | 2                  |                                                                                                |
|                  |                    | Reserved. Must contain 0.                                                                      |
| <b>17</b>        | 1                  |                                                                                                |
| <b>x_auxtype</b> |                    | Auxiliary symbol type(XCOFF64 only)                                                            |

#### Field Definitions

The following defines the fields listed above:

| Item      | Description                                                                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x_fname   | Specifies the source file name or compiler-related string.<br><br>If the file name or string is longer than 8 bytes, the field is interpreted as the following two fields: |
|           | <b>x_zeroes</b><br>A value of 0 indicates that the source file string is in the string table (overlays first 4 bytes of x_fname ).                                         |
|           | <b>x_offset</b><br>Specifies the offset from the beginning of the string table to the first byte of the source file string (overlays last 4 bytes of x_fname ).            |
| x_ftype   | Specifies the source-file string type.                                                                                                                                     |
|           | <b>0 XFT_FN</b><br>Specifies the source-file name                                                                                                                          |
|           | <b>1 XFT_CT</b><br>Specifies the compiler time stamp                                                                                                                       |
|           | <b>2 XFT_CV</b><br>Specifies the compiler version number                                                                                                                   |
|           | <b>128 XFT_CD</b><br>Specifies compiler-defined information                                                                                                                |
| (no name) | Reserved. This field must contain 2 bytes of 0.                                                                                                                            |
| x_auxtype | (XCOFF64 only) Specifies the type of auxiliary entry. Contains _AUX_FILE for this auxiliary entry.                                                                         |

If the file auxiliary entry is not used, the symbol name is the name of the source file. If the file auxiliary entry is used, then the symbol name should be .file, and the first file auxiliary entry (by convention) contains the source file name. More than one file auxiliary entry is permitted for a given symbol table entry. The n\_numaux field contains the number of file auxiliary entries.

### csect Auxiliary Entry for C\_EXT, C\_WEAKEXT, and C\_HIDEEXT Symbols

The csect auxiliary entry identifies csects (section definitions), entry points (label definitions), and external references (label declarations). A csect auxiliary entry is required for each symbol table entry that has a storage class value of C\_EXT, C\_WEAKEXT, or C\_HIDEEXT. See "Symbol Table Entry (syms.h)" for more information. By convention, the csect auxiliary entry in an XCOFF32 file must be the last auxiliary entry for any external symbol that has more than one auxiliary entry. The C language structure for a csect auxiliary entry can be found in the **x\_csect** structure in the **syms.h** file.

*Table 27. csect Auxiliary Entry Format*

| Field Name and Description                                                                  | XCOFF32                                                                            | XCOFF64                                                                            |
|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| x_scnlen<br>(See field definition section)                                                  | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> |
| x_scnlen_lo<br>(See field definition section)<br>Low 4 bytes of section length              | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 4</li> </ul>     |
| x_parmhash<br>Offset of parameter type-check hash in .typchk section                        | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>     |
| x_snhash<br>.typchk section number                                                          | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 2</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 2</li> </ul>     |

## Field Definitions

The following defines the fields listed above:

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x_scnlen</b>   | Specifies a meaning dependent on <b>x_smtyp</b> as follows:<br><br>If            Then<br><br><b>XTY_SD</b><br>x_scnlen contains the csect length.<br><br><b>XTY_LD</b><br>x_scnlen contains the symbol table index of the containing csect.<br><br><b>XTY_CM</b><br>x_scnlen contains the csect length.<br><br><b>XTY_ER</b> x_scnlen contains 0.<br>In the XCOFF64 format, the value of <b>x_scnlen</b> is divided into two fields: <b>x_scnlen_hi</b> , representing the upper 4 bytes of the value, and <b>x_scnlen_lo</b> , representing the lower 4 bytes of the value. |
| <b>x_parmhash</b> | Specifies the byte offset of the parameter type-check string in the .typchk section. The byte offset is from the beginning of the .typchk section in an XCOFF file. The byte offset points to the first byte of the parameter type-check string (not to its length field). See "Type-Check Section" for more information. A value of 0 in the <b>x_parmhash</b> field indicates that the parameter type-checking string is not present for this symbol, and the symbol will be treated as having a universal hash. The value should be 0 for C_HIDEXT symbols.               |
| <b>x_snhash</b>   | Specifies the .typchk section number. The XCOFF section number containing the parameter type-checking strings. The section numbers are one-based. For compatibility with object files generated by some compilers, if <b>x_parmhash</b> is not equal to 0 but <b>x_snhash</b> does equal 0, then the first .typchk section in the file is used. The value should be 0 for C_HIDEXT symbols.                                                                                                                                                                                  |
| <b>x_smtyp</b>    | Specifies symbol alignment and type:<br><br><b>Bits 0-4</b> Contains a 5-bit csect address alignment value (log base 2). For example, a value of 3 in this field indicates 23, or 8, meaning the csect is to be aligned on an 8-byte address value. The alignment value is used only when the value of bits 5-7 of the <b>x_smtyp</b> field is either <b>XTY_SD</b> or <b>XTY_CM</b> .<br><br><b>Bits 5-7</b> Contains a 3-bit symbol type field. See the definitions for bits 5-7 of the <b>l_smtyp</b> field in "Loader Section" for more information.                     |

| <b>Item</b>                                                                                            | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x_smclas                                                                                               | Specifies the csect storage-mapping class. This field permits the binder to arrange csects by their storage-mapping class. The x_smclas field is used only when the value of bits 5-7 of the x_smtyp field is either XTY_SD or XTY_CM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| The following storage-mapping classes are read-only and normally mapped to the .text section:          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>0 XMC_PR</b>                                                                                        | Specifies program code. The csect contains the executable instructions of the program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>1 XMC_RO</b>                                                                                        | Specifies a read-only constant. The csect contains data that is constant and will not change during execution of the program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>2 XMC_DB</b>                                                                                        | Specifies the debug dictionary table. The csect contains symbolic-debugging data or exception-processing data. This storage mapping class was defined to permit compilers with special symbolic-debugging or exception-processing requirements to place data in csects that are loaded at execution time but that can be collected separately from the executable code of the program.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>6 XMC_GL</b>                                                                                        | Specifies global linkage. The csect provides the interface code necessary to handle csect relative calls to a target symbol that can be out-of-module. This global linkage csect has the same name as the target symbol and becomes the local target of the relative calls. As a result, the csect maintains position-independent code within the .text section of the executable XCOFF object file.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>7 XMC_XO</b>                                                                                        | Specifies extended operation. A csect of this type has no dependency on (references through) the TOC. It is intended to reside at a fixed address in memory such that it can be the target of a branch-absolute instruction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>5 XMC_RW</b>                                                                                        | Specifies read/write data. A csect of this type contains initialized or uninitialized data that is permitted to be modified during program execution. If the x_smtyp value is XTY_SD, the csect contains initialized data and is mapped into the .data section. If the x_smtyp value is XTY_CM, the csect is uninitialized and is mapped into the .bss section. Typically, all the initialized static data from a C source file is contained in a single csect of this type. The csect would have a storage class value of C_HIDEEXT. An initialized definition for a global data scalar or structure from a C source file is contained in its own csect of this type. The csect would have a storage class value of C_EXT. A csect of this type is accessible by name references from other object files. |

| Item               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Value Class        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>15 XMC_TC0</b>  | Specifies TOC anchor for TOC addressability. This is a zero-length csect whose <i>n_value</i> address provides the base address for TOC relative addressability. Only one csect of type <b>XMC_TC0</b> is permitted per section of an XCOFF object file. In implementations that permit compilers and assemblers to generate multiple .data sections, there must be a csect of type <b>XMC_TC0</b> in each section that contains data that is referenced (by way of a relocation entry) as a TOC-relative data item. Some hardware architectures limit the value that a relative displacement field within a load instruction may contain. This limit then becomes an inherent limit on the size of a TOC for an executable XCOFF object. For RS/6000®, this limit is 65,536 bytes, or 16,384 4-byte TOC entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>3 XMC_TC</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>22 XMC_TE</b>   | Specifies general TOC entries. Csects of this type are the same size as a pointer and contain the address of other csects or global symbols. These csects provide addressability to other csects or symbols. The symbols might be in either the local executable XCOFF object or another executable XCOFF object. The binder uses special processing semantics to eliminate duplicate TOC entries as follows: <ul style="list-style-type: none"> <li>• Symbols that have a storage class value of <b>C_EXT</b> are global symbols and must have names (a non-null <i>n_name</i> field). These symbols require no special TOC processing logic to combine duplicate entries. Duplicate entries with the same <i>n_name</i> value are combined into a single entry.</li> <li>• Symbols that have a storage class value of <b>C_HIDEXT</b> are not global symbols, and duplicate entries are resolved by context. Any two such symbols are defined as duplicates and combined into a single entry whenever the following conditions are met: <ul style="list-style-type: none"> <li>– The <i>n_name</i> fields are the same. That is, they have either a null name or the same name string.</li> <li>– Each is the same size as a pointer.</li> <li>– Each has a single RLD entry that references external symbols with the same name.</li> </ul> </li> </ul> To minimize the number of duplicate TOC entries that the binder cannot combine, compilers and assemblers should adhere to a common naming convention for TOC entries. By convention, compilers and assemblers produce TOC entries that have a storage class value of <b>C_HIDEXT</b> and an <i>n_name</i> string that is the same as the <i>n_name</i> value for the symbol that the TOC entry addresses. |
|                    | Storage-mapping classes <b>XMC_TC</b> and <b>XMC_TE</b> are equivalent, except that the binder should map <b>XMC_TE</b> symbols after <b>XMC_TC</b> and <b>XMC_TD</b> symbols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Value Class</b>   | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>16 XMC_TD</b>     | <p>Specifies scalar data entry in the TOC. A csect that is a special form of an <b>XMC_RW</b> csect that is directly accessed from the TOC by compiler generated code. This lets some frequently used global symbols be accessed directly from the TOC rather than indirectly through an address pointer csect contained in the TOC. A csect of type <b>XMC_TD</b> has the following characteristics:</p> <ul style="list-style-type: none"> <li>• The compiler generates code that is TOC relative to directly access the data contained in the csect of type <b>XMC_TD</b>.</li> <li>• It is 4-bytes long or less.</li> <li>• It has initialized data that can be modified as the program runs.</li> <li>• If a same named csect of type <b>XMC_RW</b> or <b>XMC_UA</b> exist, it is replaced by the <b>XMC_TD</b> csect.</li> </ul> <p>For the cases where TOC scalar cannot reside in the TOC, the binder must be capable of transforming the compiler generated TOC relative instruction into a conventional indirect addressing instruction sequence. This transformation is necessary if the TOC scalar is contained in a shared object.</p> |
| <b>10 XMC_DS</b>     | <p>Specifies a csect containing a function descriptor, which contains the following three values:</p> <ul style="list-style-type: none"> <li>• The address of the executable code for a function.</li> <li>• The address of the TOC anchor (TOC base address) of the module that contains the function.</li> <li>• The environment pointer (used by languages such as Pascal and PL/I).</li> </ul> <p>There is only one function descriptor csect for a function, and it must be contained within the same executable as the function itself is contained. The function descriptor has a storage class value of <b>C_EXT</b> and has an <i>n_name</i> value that is the same as the name of the function in the source file. The addresses of function descriptors are imported to and exported from an executable XCOFF file.</p>                                                                                                                                                                                                                                                                                                                  |
| <b>8 XMC_SV</b>      | <p>Specifies 32-bit supervisor call descriptor csect. The supervisor call descriptors are contained within the operating system kernel. To an application program, the reference to a supervisor call descriptor is treated the same as a reference to a regular function descriptor. It is through the import/export mechanism that a function descriptor is treated as a supervisor call descriptor. These symbols are only available to 32-bit programs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>17 XMC_SV64</b>   | <p>Specifies 64-bit supervisor call descriptor csect. See <b>XMV_SV</b> for supervisor call information. These symbols are only available to 64-bit programs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>18 XMC_SV3264</b> | <p>Specifies supervisor call descriptor csect for both 32-bit and 64-bit. See <b>XMV_SV</b> for supervisor call information. These symbols are available to both 32-bit and 64-bit programs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>4 XMC_UA</b>      | <p>Unclassified. This csect is treated as read/write. This csect is frequently produced by an assembler or object file translator program that cannot determine the true classification of the resultant csect.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

This type of csect must have a <i>x_smtyp</i> value of <b>XTY_CM</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Item               | Description                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x_smclas continued | Value Class                                                                                                                                                                                                                                                  |
|                    | Description                                                                                                                                                                                                                                                  |
| <b>11 XMC_UC</b>   | Specifies unnamed FORTRAN common. A csect of this type is intended for an unnamed and uninitialized FORTRAN common. It is intended to be mapped into the .bss section. This type of csect must have a x_smtyp value of <b>XTY_CM</b> .                       |
|                    | The following storage mapping class is read-write and is mapped to the .tdata section:                                                                                                                                                                       |
| <b>20 XMC_TL</b>   | Specifies read/write thread-local data. A csect of this type contains initialized data that is local to every thread in a process. When a new thread is created, a csect with type <b>XMC_TL</b> is used to initialize the thread-local data for the thread. |
|                    | The following storage mapping class is read-write and is mapped to the .tbss section:                                                                                                                                                                        |
| <b>21 XMC_UL</b>   | Specifies read/write thread-local data. A csect of this type contains uninitialized data that is local to every thread in a process. When a new thread is created, the thread-local storage for a csect of this type is initialized to zero.                 |
| x_stab             | Reserved (Unused for 64-bit).                                                                                                                                                                                                                                |
| x_snstab           | Reserved (Unused for 64-bit).                                                                                                                                                                                                                                |

## Auxiliary Entries for the C\_EXT, C\_WEAKEXT, and C\_HIDEXT Symbols

Auxiliary symbol table entries are defined in XCOFF to contain reference and size information associated with a defined function. These auxiliary entries are produced by compilers and assembler for use by the symbolic debuggers. In XCOFF32, a function auxiliary symbol table entry contains the required information. In XCOFF64, both a function auxiliary entry and an exception auxiliary entry may be needed. When both auxiliary entries are generated for a single **C\_EXT**, **C\_WEAKEXT**, or **C\_HIDEXT** symbol, the **x\_size** and **x\_endndx** fields must have the same values.

The function auxiliary symbol table entry is defined in the following table.

*Table 28. Function Auxiliary Entry Format*

| Field Name and Description                                            | XCOFF32                                                                            | XCOFF64                                                                            |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| <b>x_exptr</b> File offset to exception table entry                   | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> |
| <b>x_fsize</b> Size of function in bytes                              | <ul style="list-style-type: none"> <li>Offset: 4</li> <li>Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 4</li> </ul>     |
| <b>x_lnnopt</b> File pointer to line number                           | <ul style="list-style-type: none"> <li>Offset: 8</li> <li>Length: 4</li> </ul>     | <ul style="list-style-type: none"> <li>Offset: 0</li> <li>Length: 8</li> </ul>     |
| <b>x_endndx</b> Symbol table index of next entry beyond this function | <ul style="list-style-type: none"> <li>Offset: 12</li> <li>Length: 4</li> </ul>    | <ul style="list-style-type: none"> <li>Offset: 12</li> <li>Length: 4</li> </ul>    |
| <b>(pad)</b> Unused                                                   | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 1</li> </ul>    | <ul style="list-style-type: none"> <li>Offset: 16</li> <li>Length: 1</li> </ul>    |
| <b>x_auxtype</b>                                                      | <ul style="list-style-type: none"> <li>Offset: N/A</li> <li>Length: N/A</li> </ul> | <ul style="list-style-type: none"> <li>Offset: 17</li> <li>Length: 1</li> </ul>    |
| Contains _AUX_FCN; Type of auxiliary entry                            |                                                                                    |                                                                                    |

## Field Definitions

The following defines the fields listed in the Function Auxiliary Entry Format table:

| Item      | Description                                                                                                                                                                                                                                          |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x_expr    | (XCOFF32 only) This field is a file pointer to an exception table entry. The value is the byte offset from the beginning of the XCOFF object file. In an XCOFF64 file, the exception table offsets are in an exception auxiliary symbol table entry. |
| x_fsize   | Specifies the size of the function in bytes.                                                                                                                                                                                                         |
| x_lnnoptr | Specifies a file pointer to the line number. The value is the byte offset from the beginning of the XCOFF object file.                                                                                                                               |
| x_endndx  | Specifies the symbol table index of the next entry beyond this function.                                                                                                                                                                             |

The exception auxiliary symbol table entry, defined in XCOFF64 only, is shown in the following table.

*Table 29. Exception Auxiliary Entry Format (XCOFF64 only)*

| Offset | Length | Name and Description                                              |
|--------|--------|-------------------------------------------------------------------|
| 0      | 8      | x_expr File offset to exception table entry.                      |
| 8      | 4      | x_fsize Size of function in bytes                                 |
| 12     | 4      | x_endndx<br>Symbol table index of next entry beyond this function |
| 16     | 1      | (pad) Unused                                                      |
| 17     | 1      | x_auxtype<br>Contains _AUX_EXCEPT; Type of auxiliary entry        |

## Field Definitions

The following defines the fields listed in the Exception Auxiliary Entry Format table:

| Item     | Description                                                                                                                         |
|----------|-------------------------------------------------------------------------------------------------------------------------------------|
| x_expr   | This field is a file pointer to an exception table entry. The value is the byte offset from the beginning of the XCOFF object file. |
| x_fsize  | Specifies the size of the function in bytes.                                                                                        |
| x_endndx | Specifies the symbol table index of the next entry beyond this function.                                                            |

## Block Auxiliary Entry for the C\_BLOCK and C\_FCN Symbols

The auxiliary symbol table entry is defined in XCOFF to provide information associated with the begin and end blocks of functions. The auxiliary symbol table entry is produced by compilers for use by the symbolic debuggers.

*Table 30. Table Entry Format*

| Field Name and Description                               | XCOFF32                                                                                | XCOFF64                                                                                |
|----------------------------------------------------------|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------|
| (no name)<br>Reserved                                    | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 2</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> |
| x_lnnohi<br>High-order 2 bytes of the source line number | <ul style="list-style-type: none"> <li>• Offset: 2</li> <li>• Length: 2</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> |
| x_lnno<br>Low-order 2 bytes of the source line number    | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 2</li> </ul>     | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> |
| x_lnno<br>Source line number                             | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 0</li> <li>• Length: 4</li> </ul>     |
| (no name)<br>Reserved                                    | <ul style="list-style-type: none"> <li>• Offset: 6</li> <li>• Length: 12</li> </ul>    | <ul style="list-style-type: none"> <li>• Offset: 4</li> <li>• Length: 13</li> </ul>    |

*Table 30. Table Entry Format (continued)*

| Field Name and Description                                     | XCOFF32                                                                                | XCOFF64                                                                             |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>x_auxtype</b><br>Contains _AUX_SYM; Type of auxiliary entry | <ul style="list-style-type: none"> <li>• Offset: N/A</li> <li>• Length: N/A</li> </ul> | <ul style="list-style-type: none"> <li>• Offset: 17</li> <li>• Length: 1</li> </ul> |

## Field Definitions

The following defines the fields above:

| Item      | Description                                                                                                                |
|-----------|----------------------------------------------------------------------------------------------------------------------------|
| (no name) | Reserved.                                                                                                                  |
| x_lnnohi  | For XCOFF32, specifies the high-order 16 bits of a source file line number.                                                |
| x_lnno    | Specifies the line number of a source file. The maximum value of this field is 65535 for XCOFF64 and $2^{32}$ for XCOFF32. |

## Section Auxiliary Entry for the C\_STAT Symbol

The section auxiliary symbol table entry ID is defined in XCOFF32 to provide information in the symbol table concerning the size of sections produced by a compiler or assembler. The generation of this information by a compiler is optional, and is ignored and removed by the binder.

*Table 31. Section Auxiliary Entry Format (XCOFF32 Only)*

| Offset | Length in Bytes | Name and Description                            |
|--------|-----------------|-------------------------------------------------|
| 0      | 4               | <b>x_scnlen</b><br>Section length               |
| 4      | 2               | <b>x_nreloc</b><br>Number of relocation entries |
| 6      | 2               | <b>x_nlinno</b><br>Number of line numbers       |
| 8      | 10              | (no name)<br>Reserved                           |

## Field Definitions

The following list defines the fields:

| Item      | Description                                                                           |
|-----------|---------------------------------------------------------------------------------------|
| x_scnlen  | Specifies section length in bytes.                                                    |
| x_nreloc  | Specifies the number of relocation entries. The maximum value of this field is 65535. |
| x_nlinno  | Specifies the number of line numbers. The maximum value of this field is 65535.       |
| (no name) | Reserved.                                                                             |

For general information on the XCOFF file format, see "XCOFF Object File Format." For more information on the symbol table, see "Symbol Table Information."

For information on debugging, see "Debug Section."

## Symbol Table Field Contents by Storage Class

This section defines the symbol table field contents for each of the defined storage classes (`n_sclass`) that are used in XCOFF. The following table lists storage class entries in alphabetic order. See "Symbol Table

Entry (syms.h)" for more information.

*Table 32. Symbol Table by Storage Class*

**Class Definition**

**C\_BCOMM** 135 Beginning of common block

**Field Contents**

**n\_name** Name of the common block\*

**n\_value** 0, undefined

**n\_snum**  
N\_DEBUG

**Aux. Entry**

**C\_BINCL** 108 Beginning of include file

**n\_name** Source name of the include file\*\*

**n\_value** File pointer

**n\_snum**  
N\_DEBUG

**Aux. Entry**

**C\_BLOCK** 100 Beginning or end of inner block

**n\_name** .bb or .eb

**n\_value** Relocatable address

**n\_snum**  
N\_SCNUM

**Aux. Entry**  
BLOCK

**C\_BSTAT** 143 Beginning of static block

**n\_name** .bs

**n\_value** Symbol table index

**n\_snum**  
N\_DEBUG

**Aux. Entry**

**C\_DECL** 140 Declaration of object (type)

**n\_name** Debugger stabstring\*

**n\_value** 0, undefined

**n\_snum**  
N\_SCNUM

**Aux. Entry**

**C\_ECOML** 136 Local member of common block

**n\_name** Debugger stabstring\*

**n\_value** Offset within common block

**n\_snum**  
N\_ABS

**Aux. Entry**

**C\_ECOMM** 137 End of common block

**n\_name** Debugger stabstring\*

**n\_value** 0, undefined

**n\_snum**  
N\_DEBUG

**Aux. Entry**

| <b>C_WEAKEXT</b> 111 Weak external symbol (defining weak external symbols for binder processing)                                                                                               | <p><b>n_name</b> Symbol Name**</p> <p><b>n_value</b> Relocatable address</p> <p><b>n_scnum</b><br/>N_SCNUM or N_UNDEF</p> <p><b>Aux. Entry</b><br/>FUNCTION CSECT</p> |

**Note:**

1. \*For long name, the n\_offset value is an offset into the .debug section.
2. \*\*For long name, the n\_offset value is an offset into the string table.

### **Storage Classes by Usage and Symbol Value Classification**

Following are the storage classes used and relocated by the binder. The symbol values (n\_value) are addresses.

| <b>Class</b>     | <b>Description</b>                                             |
|------------------|----------------------------------------------------------------|
| <b>C_EXT</b>     | Specifies an external or global symbol                         |
| <b>C_WEAKEXT</b> | Specifies an external or global symbol with weak binding       |
| <b>C_HIDEEXT</b> | Specifies an internal symbol                                   |
| <b>C_BLOCK</b>   | Specifies the beginning or end of an inner block (.bb or .eb)  |
| <b>C_FCN</b>     | Specifies the beginning or end of a function (.bf or .ef only) |
| <b>C_STAT</b>    | Specifies a static symbol (contained in statics csect)         |

Following are storage classes used by the binder and symbolic debugger or by other utilities for file scoping and accessing purposes:

| <b>Class</b>   | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>C_FILE</b>  | Specifies the source file name. The n_value field holds the symbol index of the next file entry. The n_name field is the name of the file.                                                                                                                                                                                                                                                          |
| <b>C_BINCL</b> | Specifies the beginning of include header file. The n_value field is the line number byte offset in the object file to the first line number from the include file.                                                                                                                                                                                                                                 |
| <b>C_EINCL</b> | Specifies the end of include header file. The n_value field is the line number byte offset in the object file to last line number from the include file.                                                                                                                                                                                                                                            |
| <b>C_INFO</b>  | Specifies the location of a string in the comment section. The n_value field is the offset to a string of bytes in the specified STYP_INFO section. The string is preceded by a 4-byte length field. The n_name field is preserved by the binder. An application-defined unique name in this field can be used to filter access to only those comment section strings intended for the application. |

Following are the storage classes that exist only for symbolic debugging purposes:

| <b>Item</b>    | <b>Description</b>                                                                                                                                   |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>C_BCOMM</b> | Specifies the beginning of a common block. The n_value field is meaningless; the name is the name of the common block.                               |
| <b>C_ECOML</b> | Specifies a local member of a common block. The n_value field is byte-offset within the common block.                                                |
| <b>C_ECOMM</b> | Specifies the end of a common block. The n_value field is meaningless.                                                                               |
| <b>C_BSTAT</b> | Specifies the beginning of a static block. The n_value field is the symbol table index of the csect containing static symbols; the name is .bs.      |
| <b>C_ESTAT</b> | Specifies the end of a static block. The n_value field is meaningless; the name is .es.                                                              |
| <b>C_DECL</b>  | Specifies a declaration of object (type declarations). The n_value field is undefined.                                                               |
| <b>C_ENTRY</b> | Specifies an alternate entry (FORTRAN) and has a corresponding C_EXT or C_WEAKEXT symbol. The n_value field is undefined.                            |
| <b>C_FUN</b>   | Specifies a function or procedure. May have a corresponding C_EXT or C_WEAKEXT symbol. The n_value field is byte-offset within the containing csect. |
| <b>C_GSYM</b>  | Specifies a global variable and has a corresponding C_EXT or C_WEAKEXT symbol. The n_value field is undefined.                                       |
| <b>C_LSYM</b>  | Specifies an automatic variable allocated on the stack. The n_value field is byte offset relative to the stack frame (platform dependent).           |
| <b>C_PSYM</b>  | Specifies an argument to a subroutine allocated on the stack. The n_value field is byte-offset relative to the stack frame (platform dependent).     |
| <b>C_RSYM</b>  | Specifies a register variable. The n_value field is the register number.                                                                             |
| <b>C_RPSYM</b> | Specifies an argument to a function or procedure stored in a register. The n_value field is the register number where argument is stored.            |
| <b>C_STSYM</b> | Specifies a statically allocated symbol. The n_value field is byte-offset within csect pointed to by containing C_BSTAT entry.                       |
| <b>C_GTLS</b>  | Specifies a global thread-local variable and follows a C_EXT or C_WEAKEXT symbol with the same name. The n_value field is undefined.                 |

| Item    | Description                                                                                                                |
|---------|----------------------------------------------------------------------------------------------------------------------------|
| C_STTLS | Specifies a static thread-local variable and follows a C_HIDEXT symbol with the same name. The n_value field is undefined. |

For general information on the XCOFF file format, see "XCOFF Object File Format." For more information on the symbol table, see "Symbol Table Information."

For information on debugging, see "Debug Section."

## String Table

IN XCOFF32, the string table contains the names of symbols that are longer than 8 bytes. In XCOFF64, the string table contains the names of all symbols. If the string table is present, the first 4 bytes contain the length (in bytes) of the string table, including the length of this length field. The remainder of the table is a sequence of null-terminated ASCII strings. If the n\_zeroes field in the symbol table entry is 0, then the n\_offset field gives the byte offset into the string table of the name of the symbol.

If a string table is not used, it may be omitted entirely, or a string table consisting of only the length field (containing a value of 0 or 4) may be used. A value of 4 is preferable. The following table shows string table organization.

*Table 33. String Table Organization*

| Offset | Length in Bytes | Description                                                                 |
|--------|-----------------|-----------------------------------------------------------------------------|
| 0      | 4               | Length of string table.                                                     |
| 4      | <i>n</i>        | Symbol name string, null-terminated.<br>Field repeats for each symbol name. |

For general information on the XCOFF file format, see "XCOFF Object File Format."

## dbx Stabstrings

The debug section contains the symbolic debugger stabstrings (symbol table strings). It is generated by the compilers and assemblers. It provides symbol attribute information for use by the symbolic debugger.

See "Debug Section" for a general discussion.

### Stabstring Terminal Symbols

In the stabstring grammar, there are five types of terminal symbols, which are written in all capital letters. These symbols are described by the regular expressions in the following list:

**Note:** The [ ] (brackets) denote one instance, [ ]\* (brackets asterisk) denote zero or more instances, [ ]+ (brackets plus sign) denote one or more instances, ( ) (parentheses) denote zero or one instance, .\* (dot asterisk) denotes a sequence of zero or more bytes, and | (pipe) denotes alternatives.

| Symbol     | Regular Expression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME       | [^ ; '"] (A name consists of any non-empty set of characters, excluding ; : ' or ".)                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| STRING     | '*''   ".*", where \"', '\', or \\ can be used inside the string                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|            | Within a string, the \ (backslash character) may have a special meaning. If the character following the \ is another \, one of the backslashes is ignored. If the next character is the quote character used for the current string, the string is interpreted as containing an embedded quote. Otherwise, the \ is interpreted literally. However, if the closing quote is the last character in the stabstring, and a \ occurs immediately before the quote, the \ is interpreted literally. This use is not recommended. |
|            | The \ must be quoted only in the following instances:                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | <ul style="list-style-type: none"> <li>• The \ is the last character in the string (to avoid having the closing quote escaped).</li> <li>• The \ is followed by the current quote character.</li> <li>• The \ is followed by another \.</li> </ul>                                                                                                                                                                                                                                                                          |
|            | An escaped quote is required only when a single string contains both a single quote and a double quote. Otherwise, the string should be quoted with the quote character not contained in the strings.                                                                                                                                                                                                                                                                                                                       |
|            | A string can contain embedded null characters, so utilities that process stabstrings must use the length field to determine the length of a stabstring.                                                                                                                                                                                                                                                                                                                                                                     |
| INTEGER    | (-)[0-9]+                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| HEXINTEGER | [0-9A-F]+                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|            | The hexadecimal digits A-F must be uppercase.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Stabstring Grammar

REALs may be preceded by white space, and STRINGs may contain any characters, including null and blank characters. Otherwise, there are no null or blank characters in a stabstring.

Long stabstrings can be split across multiple symbol table entries for easier handling. In the stabstring grammar, a # (pound sign) indicates a point at which a stabstring may be continued. A continuation is indicated by using either the ? (question mark) or \ as the last character in the string. The next part of the stabstring is in the name of the next symbol table entry. If an alternative for a production is empty, the grammar shows the keyword /\*EMPTY\*/.

The following list contains the stabstring grammar:

### *Stabstring:*

Basic structure of stabstring:

#### **NAME : Class**

Name of object followed by object classification

:Class Unnamed object classification.

**Class:** Object classifications:

#### **c = Constant ;**

Constant object

### *NamedType*

User-defined types and tags

### *Parameter*

Argument to subprogram

### *Procedure*

Subprogram declaration

### *Variable*

Variable in program

*Label* Label object.

*Constant:*

Constant declarations:

**b** *OrdValue*

Boolean constant

**c** *OrdValue*

Character constant

**e** *TypeID* , *OrdValue*

Enumeration constant

**i** **INTEGER**

Integer constant

**r** **REAL**

Decimal or binary floating point constant

**s** **STRING**

String constant

**C** **REAL, REAL**

Complex constant

**S** *TypeID* , *NumElements* , *NumBits* , *BitPattern*

Set constant.

*OrdValue:*

Associated numeric value: INTEGER

*NumElements:*

Number of elements in the set: INTEGER

*NumBits:*

Number of bits in item: INTEGER

*NumBytes:*

Number of bytes in item: INTEGER

*BitPattern:*

Hexadecimal representation, up to 32 bytes: HEXINTEGER

*NamedType:*

User-defined types and tags:

**t** *TypeID*

User-defined type (TYPE or typedef), excluding those that are valid for T *TypeID*

**T** *TypeID*

Struct, union, class, or enumeration tag

*Parameter:*

Argument to procedure or function:

**a** *TypeID*

Passed by reference in general register

**p** *TypeID*

Passed by value on stack

**v** *TypeID*

Passed by reference on stack

**C** *TypeID*

Constant passed by value on stack

- D** *TypeID*  
Passed by value in floating point register
- R** *TypeID*  
Passed by value in general register
- X** *TypeID*  
Passed by value in vector register

*Procedure:*

- Proc* Procedure or function declaration:
- Proc , NAME : NAME* Procedure named 1st NAME, local to 2nd NAME, where 2nd NAME is different from the current scope.

*Variable:*

- Variable in program:
- TypeID* Local (automatic) variable of type *TypeID*
- d** *TypeID* Floating register variable of type *TypeID*
- h***TypeID* Static thread-local variable of type *TypeID*
- r** *TypeID* Register variable of type *TypeID*
- x** *TypeID* Vector register variable of type *TypeID*
- G** *TypeID* Global (external) variable of type *TypeID*
- H** *TypeID* Global (external) thread-local variable of type *TypeID*
- S** *TypeID* Module variable of type *TypeID* (C static global)
- V** *TypeID* Own variable of type *TypeID* (C static local)
- Y** FORTRAN pointer variable
- Z** *TypeID NAME* FORTRAN pointee variable

*Label:* Label:

- L** Label name.

*Proc:* Different types of functions and procedures:

- f** *TypeID* Private function of type *TypeID*
- g** *TypeID* Generic function (FORTRAN)
- m** *TypeID* Module (Modula-2, ext. Pascal)

**J** *TypeID*

Internal function of type *TypeID*

**F** *TypeID*

External function of type *TypeID*

**I** (capital i) Internal procedure

**P** External procedure

**Q** Private procedure

*TypeID*:

Type declarations and identifiers:

**INTEGER**

Type number of previously defined type

**INTEGER = TypeDef**

New type number described by *TypeDef*

**INTEGER = TypeAttrs TypeDef**

New type with special type attributes

*TypeAttrs*:

@ *TypeAttrList* ;

**Note:** Type attributes (*TypeAttrs*) are extra information associated with a type, such as alignment constraints or pointer-checking semantics. The **dbx** program recognizes only the **size** attribute and the **packed** attribute. The **size** attribute denotes the total size of a padded element within an array. The **packed** attribute indicates that a type is a packed type. Any other attributes are ignored by **dbx**.

*TypeAttrList*:

List of special type attributes:

*TypeAttrList* ;

  @ *TypeAttr* *TypeAttr*

*TypeAttr*:

Special type attributes:

**a** **INTEGER**

Align boundary

**s** **INTEGER**

Size in bits

**p** **INTEGER**

Pointer class (for checking)

**P** Packed type

*Other* Anything not covered is skipped entirely

*TypeDef*:

Basic descriptions of objects:

**INTEGER**

Type number of a previously defined type

**b** *TypeID* ; # *NumBytes*

Pascal space type

**c** *TypeID* ; # *NumBits*

Complex type *TypeID*

**d** *TypeID*

File of type *TypeID*

**e** *EnumSpec* ;

Enumerated type (default size, 32 bits)

**g** *TypeID* ; # *NumBits*

Floating-point type of size *NumBits*

**D** *TypeID* ; # *NumBits*

Decimal floating-point type of size *NumBits*

For **i** types, *ModuleName* refers to the Modula-2 module from which it is imported.

**i** **NAME** : **NAME** ;

Imported type *ModuleName:Name*

**i** **NAME** : **NAME** , *TypeID* ;

Imported type *ModuleName:Name* of type *TypeID*

**k** *TypeID*

C++ constant type

**l** ; # Usage-is-index; specific to COBOL

**m** *OptVBaseSpec* *OptMultiBaseSpec* *TypeID* : *TypeID* : *TypeID* ;

C++ pointer to member type; the first *TypeID* is the member type; the second is the type of the class

**n** *TypeID* ; # *NumBytes*

String type, with maximum string length indicated by *NumBytes*

**o** **NAME** ;

Opaque type

**o** **NAME** , *TypeID*

Opaque type with definition of *TypeID*

**w** *TypeID*

Wide character

**z** *TypeID* ; # *NumBytes*

Pascal gstring type

**C** *Usage*

COBOL Picture

**I** *NumBytes* ; # *PicSize*

(uppercase i) Index is type; specific to COBOL

**K** *CobolFileDesc*;

COBOL File Descriptor

**M** *TypeID* ; # **Bound**

Multiple instance type of *TypeID* with length indicated by Bound

**N**      Pascal *Stringptr*

**S** *TypeID*

Set of type *TypeID*

\* *TypeID*

Pointer of type *TypeID*

& *TypeID*

C++ reference type

**V** *TypeID*  
C++ volatile type

**Z** C++ ellipses parameter type

*Array Subrange ProcedureType*  
For function types rather than declarations

*Record* Record, structure, union, or group types

*EnumSpec:*  
List of enumerated scalars:

*EnumList*  
Enumerated type (C and other languages)

*TypeID : EnumList*  
C++ enumerated type with repeating integer type

*EnumList: Enum*  
*EnumList Enum*

*Enum:* Enumerated scalar description: NAME : *OrdValue* , #

*Array:* Array descriptions:

**a** *TypeID* ; # *TypeID*  
Array; *FirstTypeID* is the index type

**A** *TypeID*  
Open array of *TypeID*

**D** **INTEGER** ,*TypeID*  
N-dimensional dynamic array of *TypeID*

**E** **INTEGER** , *TypeID*  
N-dimensional dynamic subarray of *TypeID*

**O** **INTEGER** , *TypeID*  
New open array

**P** *TypeID* ; # *TypeID*  
Packed array

*Subrange:*

Subrange descriptions:

**r** *TypeID* ; # *Bound* ; # *Bound*  
Subrange type (for example, char, int,\,), lower and upper bounds

*Bound:* Upper and lower bound descriptions:

**INTEGER**  
Constant bound

*Boundtype INTEGER*  
Variable or dynamic bound; value is address of or offset to bound

**J** Bound is indeterminable (no bounds)

*Boundtype:*  
Adjustable subrange descriptions:

**A** Bound passed by reference on stack

**S** Bound passed by value in static storage

**T** Bound passed by value on stack

- a**      Bound passed by reference in register
- t**      Bound passed by value in register

*ProcedureType:*

Function variables (1st type C only; others Modula-2 & Pascal)

**f** *TypeID* ;  
          Function returning type *TypeID*

**f** *TypeID* , *NumParams* ; *TParamList* ;  
          Function of N parameters returning type *TypeID*

**p** *NumParams* ; *TParamList* ;  
          Procedure of N parameters

**R** *NumParams* ; *NamedTParamList*  
          Pascal subroutine parameter

**F** *TypeID*, *NumParams* ; *NamedTParamList* ;  
          Pascal function parameter

*NumParams:*

Number of parameters in routine:

INTEGER.

*TParamList:*

Types of parameters in Modula-2 function variable:

*TParam*  
          Type of parameter and passing method

*TParam:*

Type and passing method

*TypeID* , *PassBy* ; #

*NamedTParamList:*

Types of parameters in Pascal-routine variable: /\*EMPTY\*/ *NamedTPLList*

*NamedTPLList:*

*NamedTPParam* *NamedTPLList* *NamedTPParam*

*NamedTPParam:*

Named type and passing method: *Name* : *TypeID* , *PassBy* *InitBody* ; # : *TypeID* , *PassBy* *InitBody* ; #  
          Unnamed parameter

*Record:* Types of structure declarations:

- **s** *NumBytes* # *FieldList* ;
- Structure or record definition
- **u** *NumBytes* # *FieldList* ;
- Union
- **v** *NumBytes* # *FieldList* *VariantPart* ;
- Variant Record
- **Y** *NumBytes* *ClassKey* *OptPBV* *OptBaseSpecList* ( *ExtendedFieldListOptNameResolutionList* ;
- C++ class
- **G** *Redefinition* , **n** *NumBits* # *FieldList* ;
- COBOL group without conditionals

**Gn** *NumBits* *FieldList* ;

• **G** *Redefinition* , **c** *NumBits* # *CondFieldList* ;

- COBOL group with conditionals

**Gc** *NumBits CondFieldList* ;

*OptVBaseSpec*:

**v**      ptr-to-mem class has virtual bases.

**/\*EMPTY\*/**

Class has no virtual bases.

*OptMultiBaseSpec*:

**m**      Class is multi-based.

**/\*EMPTY\*/**

Class is not multi-based.

*OptPBV*:

**V**      Class is always passed by value.

**/\*EMPTY\*/**

Class is never passed by value.

*ClassKey*:

**s**      struct

**u**      union

**c**      class

*OptBaseSpecList*:

**/\*EMPTY\*/ BaseSpecList**

*BaseSpecList*:

*BaseSpec BaseSpecList , BaseSpec*

*BaseSpec*:

*VirtualAccessSpec BaseClassOffset : ClassTypeID*

*BaseClassOffset*:

**INTEGER**

Base record offset in bytes

*ClassTypeID*:

*TypeID* Base class type identifier

*VirtualAccessSpec*:

*EditDescription:*

Cobol edit description:

**STRING**

Edit characters in an alpha PIC

**INTEGER**

Decimal point position in a numeric PIC

*PicSize:*

Cobol description length:

**INTEGER**

Number of repeated '9's in numeric clause, or length of edit format for edited numeric

*Condition:*

Conditional variable descriptions:

NAME : INTEGER = **q** *ConditionType* , *ValueList* ; #

*ConditionType:*

Condition descriptions:

*ConditionPrimitive* , *KanjiChar*

*ConditionPrimitive:*

Primitive type of Condition:

**n** *Sign DecimalSite*

Numeric conditional

**a**

Alphanumeric conditional

**f**

Figurative conditional

*Sign:* For types with explicit sign:

**+** Positive

**-** Negative

**[^+-]** Not specified

*DecimalSite:*

Number of places from left for implied decimal point:

**INTEGER**

*KanjiChar:*

0 only if Kanji character in value: INTEGER

*ValueList*

Values associated with condition names

*Value ValueList Value*

*Value* Values associated with condition names:

**INTEGER : ArbitraryCharacters #**

Integer indicates length of string

*CobolFileDesc:*

COBOL file description: *Organization AccessMethod NumBytes*

*Organization:*

COBOL file-description organization:

**i** Indexed

**l** Line Sequential

**r** Relative

**s** Sequential

*AccessMethod:*

COBOL file description access method:

**d** Dynamic

**o** Sort

**r** Random

**s** Sequential

*PassBy:*

Parameter passing method:

**INTEGER**

0 = passed-by reference; 1 = passed-by value

## Special Files

A *special file* is associated with a particular hardware device or other resource of the computer system. The operating system uses special files, sometimes called *device files*, to provide file I/O access to specific character and block device drivers.

Special files, at first glance, appear to be just like ordinary files, in that they:

- Have path names that appear in a directory.
- Have the same access protection as ordinary files.

- Can be used in almost every way that ordinary files can be used.

However, there is an important difference between the two. An ordinary file is a logical grouping of data recorded on disk. A special file, on the other hand, corresponds to a device entity. Examples are:

- An actual device, such as a line printer.
- A logical subdevice, such as a large section of the disk drive.
- A pseudo device, such as the physical memory of the computer (**/dev/mem**) or the null file (**/dev/null**).

Special files are distinguished from other files by having a file type (c or b, for character or block) stored in the i-nodes to indicate the type of device access provided. The i-node for the special file also contains the device major and minor numbers assigned to the device at device configuration time.

**Note:** Data corruption, loss of data, or loss of system integrity (a system crash) will occur if devices supporting paging, logical volumes, or mounted file systems are accessed using block special files. Block special files are provided for logical volumes and disk devices on the operating system and are solely for system use in managing file systems, paging devices, and logical volumes. These files should not be used for other purposes.

Several special files are provided with the operating system. By convention, special files are located in the **/dev** directory.

More information is provided about the following special files:

| Item                | Description                                                                                                                                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>3270cn</b>       | Provides access to 3270 connection adapters by way of the 3270 connection adapter device driver.                                                       |
| <b>bus</b>          | Provides access to the hardware bus by way of the machine I/O device driver.                                                                           |
| <b>cd</b>           | Provides access to the <b>cdrom</b> device driver.                                                                                                     |
| <b>console</b>      | Provides access to the system console.                                                                                                                 |
| <b>dials</b>        | Provides access to the dials.                                                                                                                          |
| <b>dump</b>         | Supports system dump.                                                                                                                                  |
| <b>entn</b>         | Provides access to the 3COM Ethernet adapters by way of the Ethernet device handler for this platform.                                                 |
| <b>error</b>        | Supports error logging.                                                                                                                                |
| <b>fd</b>           | Provides access to the diskette device driver.                                                                                                         |
| <b>fddin</b>        | Provides access to the FDDI device driver by way of the FDDI device handler.                                                                           |
| <b>GIO</b>          | Provides access to the graphics I/O (GIO) adapter.                                                                                                     |
| <b>ide</b>          | Provides access to the Integrated Device Electronics (IDE) adapter device driver.                                                                      |
| <b>kbd</b>          | Provides access to the natively attached keyboard.                                                                                                     |
| <b>kmem and mem</b> | Provides privileged read and write access to virtual memory.                                                                                           |
| <b>lft</b>          | Implements a low-function terminal (LFT) device.                                                                                                       |
| <b>lp</b>           | Provides access to the line printer device driver.                                                                                                     |
| <b>lpfk</b>         | Provides access to the lighted program function key (LPFK) array.                                                                                      |
| <b>lvdd</b>         | Provides access to the logical volume device driver.                                                                                                   |
| <b>mouse</b>        | Provides access to the natively attached mouse.                                                                                                        |
| <b>mpqi</b>         | Provides access to the Multiport Model 2 Adapter (MM2) SDLC device driver.                                                                             |
| <b>mpqn</b>         | Provides access to multiprotocol adapters by way of the Multiprotocol Quad Port (MPQP) device handler.                                                 |
| <b>null</b>         | Provides access to the null device.                                                                                                                    |
| <b>nvrrom</b>       | Provides access to platform-specific nonvolatile RAM used for system boot, configuration, and fatal error information.                                 |
| <b>omd</b>          | Provides access to the read/write optical device driver.                                                                                               |
| <b>opn</b>          | Provides diagnostic interface to the Serial Optical Link device driver.                                                                                |
| <b>ops0</b>         | Provides access to the Serial Optical Link device driver.                                                                                              |
| <b>pty</b>          | Provides the pseudo-terminal (pty) device driver.                                                                                                      |
| <b>random</b>       | Source of secure random output.                                                                                                                        |
| <b>rcm</b>          | Provides application interface to obtain and relinquish status of a graphics process through the <b>Rendering Context Manager (RCM)</b> device driver. |
| <b>rhdisk</b>       | Provides raw access to the physical volume (fixed-disk) device driver.                                                                                 |
| <b>rmt</b>          | Provides access to the sequential-access bulk-storage medium device driver.                                                                            |
| <b>scsi</b>         | Provides access to the SCSI adapter device driver.                                                                                                     |

| <b>Item</b>       | <b>Description</b>                                                                                                                                                          |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>tablet</b>     | Provides access to the tablet.                                                                                                                                              |
| <b>tmscsi</b>     | Provides access to the SCSI Target-mode interface by way of the SCSI <b>tmscsi</b> device driver.                                                                           |
| <b>tokn</b>       | Provides access to the token-ring adapters by way of the token-ring device handler.                                                                                         |
| <b>trace</b>      | Supports event tracing.                                                                                                                                                     |
| <b>tty</b>        | Supports the controlling terminal interface.                                                                                                                                |
| <b>urandom</b>    | Source of secure random output.                                                                                                                                             |
| <b>vty_server</b> | Creates a tty-style connection from the partition on which a virtual terminal server is running to a virtual terminal (not a virtual terminal server) on another partition. |
| <b>x25sn</b>      | Provides access to the X.25 Interface Co-Processor/2 adapters.                                                                                                              |

## 3270cn Special File

### Purpose

Provides access to 3270 connection adapters by way of the 3270 connection adapter device handler.

### Description

The **3270cn** character special file provides access to the 3270 connection adapter device handler for the purpose of emulating 3270 display stations and printers. The device handler is a multiplexed device handler that supports an independent logical 3270 session on each of its channels.

The device handler supports two modes of operation:

| <b>Item</b>                                               | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Distributed Function Terminal (DFT) mode</b>           | In DFT mode, the adapter can appear as multiple SNA or non-SNA display sessions, non-SNA printer sessions, or both, and is an intelligent device to the control unit. In this mode, the device handler provides the capability of emulating several 3278/79 display stations. If the attached control unit does not support Extended Asynchronous Event Device Status, either the control unit port or the device handler must be configured for one session only. |
| <b>3278/79 emulation Control Unit Terminal (CUT) mode</b> | In CUT mode, the adapter appears as a single-session, unintelligent device to the control unit. In this mode, the device handler provides the capability of emulating a single 3278/79 display station.                                                                                                                                                                                                                                                            |

The device handler supports up to four 3270 connection adapters, each of which may have up to five DFT sessions or one CUT session.

The **/usr/include/sys/io3270.h** file contains the definitions of the structures used by the device handler.

### Usage Considerations

When accessing the 3270 connection device handler, the following should be taken into account:

| Item                                         | Description                                                                                                                                                                                                           |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Driver initialization and termination</b> | The device handler may be loaded and unloaded. The device handler supports the configuration calls to initialize and terminate itself, but does not support the configuration call to query vital product data (VPD). |
| <b>Special file support</b>                  | Subroutines other than <b>open</b> and <b>close</b> are discussed in regard to the mode in which the device handler is operating.                                                                                     |

## Subroutine Support

The 3270 device handler provides 3270-specific support for the following subroutines:

- **open**
- **close**
- **read**
- **readx** (non-SNA DFT mode only)
- **write**
- **writex** (non-SNA DFT mode only)
- **ioctl**

### open and close Subroutines

The device handler supports the **3270cn** special file as a character-multiplex special file. The special file must be opened for both reading and writing (O\_RDWR).

A special consideration exists for closing the **3270cn** special file. If the file was opened in both CUT mode and CUT-File Transfer mode, the **close** operation for CUT-File Transfer mode must precede the **close** operation for CUT mode.

The special file name used in an **open** call takes on several different forms, depending on how the device is to be opened. Types of special file names are:

| Item                 | Description                                                                                                                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dev/3270cn/C</b>  | Starts the device handler in CUT mode for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ .                                                                                                              |
| <b>/dev/3270cn/F</b> | Starts the device handler in CUT File-Transfer mode for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ . The file must be currently open in CUT mode before it can be opened in CUT File-Transfer mode. |
| <b>/dev/3270cn/*</b> | Starts the device handler in DFT mode for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ and the * (asterisk) is defined by <i>P/a</i> , as follows:                                                    |
|                      | <b>P/00, P/01, P/02,...P/1F</b><br>The printer session specified by the <i>P</i> variable is equal to the control unit session address, and the value of <i>a</i> is less than or equal to 0x1F.                             |

| <b>/dev/3270cn</b>   | Starts the device handler in DFT mode for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ .                                                                                                              |

### read Subroutine in Non-SNA DFT Mode

Data received by the communication adapter from the host is placed in the buffer until the message is completed or the buffer is full. When either condition occurs, the driver returns program control back to the application. The application can determine the status of a **read** subroutine call by issuing a **WDC\_INQ** ioctl operation.

If the **WDC\_INQ** operation returns a status indicating that more data is available, the application should immediately issue another **read** call. Available data must be read as soon as possible to avoid degrading link or host performance.

If a **read** call is made and no data is available, the calling process is blocked until data becomes available. To avoid blocking, use the **poll** subroutine to determine if data is available.

The host sends data as an outbound 3270 data stream. The device handler translates the command codes in the outbound 3270 data stream. The command codes and translations are as follows:

| Command Code           | Into Driver | Out of Driver |
|------------------------|-------------|---------------|
| Erase All Unprotected  | 0x6F        | 0x0F          |
| Erase/Write            | 0xF5        | 0x03          |
| Erase/Write Alternate  | 0x7E        | 0x0D          |
| Read Buffer            | 0xF2        | 0x02          |
| Read Modified          | 0xF6        | 0x06          |
| Write                  | 0xF1        | 0x01          |
| Write Structured Field | 0xF3        | 0x11          |

### read Subroutine in SNA DFT Mode

The communication adapter receives data from the control unit in individual SNA data segments. The device driver notifies the application that data is available. During the **read** subroutine call, the data is transferred to the application's user space from the device driver's kernel space (without the TCA header from the control unit), and control is passed back to the application. The device driver acknowledges each SNA data segment received, making it unnecessary for the application to inquire about the link status after the **read** call.

**Note:** The **STAT\_ACK** ioctl operation is not valid in SNA DFT mode.

Unlike non-SNA DFT mode, neither chaining nor command interpretation is performed by the device driver in SNA DFT mode. The application must both accumulate SNA data segments to form an response unit (RU) and interpret any 3270 data contained within.

### readx Subroutine in Non-SNA DFT Mode

Data received by the communication adapter from the host is placed in the buffer until either the message completes or the buffer is full. Upon completion of the **read** call, the **io3270** structure pointed to by the **read** extension contains the status. One of the following status codes is set in the **io\_flags** field of the **io3270** structure:

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>WDI_DAVAIL</b> | Additional data is available for this link address.                                                                                                                                                                                                                                                                                                                                       |
| <b>WDI_COMM</b>   | A communication error occurred. The <b>io_status</b> field contains the corresponding message code.                                                                                                                                                                                                                                                                                       |
| <b>WDI_PROG</b>   | A program error occurred. The <b>io_status</b> field contains the corresponding message code.                                                                                                                                                                                                                                                                                             |
| <b>WDI_MACH</b>   | A hardware error occurred. The <b>io_status</b> field contains the corresponding message code.                                                                                                                                                                                                                                                                                            |
| <b>WDI_FATAL</b>  | An error occurred that prevents further communication with the host. This flag is optionally set in addition to the <b>WDI_COMM</b> , <b>WDI_PROG</b> , or <b>WDI_MACH</b> flag. It is also set when a coax failure occurs. In this case, the <b>io_status</b> field contains a value of <b>WEB_610</b> , but the <b>WDI_COMM</b> , <b>WDI_PROG</b> , or <b>WDI_MACH</b> flag is not set. |

When reset, the **WDI\_DAVAIL** flag indicates that the data just read marks the completion of an outbound 3270 data stream.

If the **WDI\_DAVAIL** flag indicates more data is available, another **readx** subroutine should be issued immediately. Available data must be read as soon as possible to avoid degrading link or host performance.

If a **readx** subroutine call is made and no data is available, the calling process is blocked until data becomes available. To avoid blocking, use the **poll** subroutine to determine if data is available.

Data received from the host is in the form of an outbound 3270 data stream. The device driver translates the command codes in the outbound 3270 data stream.

**Note:** The 3270 write commands require the application to send a status to the host. Status is sent using the **WDC\_SSTAT** ioctl operation.

#### **write Subroutine in Non-SNA DFT Mode**

In non-SNA DFT mode, the **write** subroutine sends an inbound 3270 data stream to the host. The buffer specified on a **write** subroutine call must contain a complete inbound 3270 data stream. The **write** call is complete when it has successfully transferred from the buffer specified on the subroutine call.

#### **write Subroutine in SNA DFT Mode**

In SNA DFT mode, the **write** subroutine transmits SNA data to the host system. This data can be either a 3270 data stream with SNA headers or an SNA response.

The application sends data to the device driver, one RU at a time. The device driver is then responsible for segmenting the inbound SNA data. If a second **write** call is made before the first call is processed, the second call does not proceed until the device driver is ready. After the data is transferred from the application's user space to the device driver's kernel space, the **write** subroutine completes and control is returned to the application.

If the device driver detects a coax disconnect between two **write** calls, the second **write** call will return to the application, with the **errno** global variable set to **EFAULT**.

#### **writex Subroutine in Non-SNA DFT Mode**

The **writex** subroutine sends an inbound 3270 data stream to the host. The buffer specified on a **writex** subroutine call must contain a complete inbound 3270 data stream.

The **write** subroutine is complete when it has successfully transferred the data from the specified buffer. Upon completion of the **write** subroutine call, the **io3270** structure pointed to by the **write** extension contains the status. One of the following status codes is set in the **io\_flags** field of the **io3270** structure:

| Item              | Description                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| <b>WDI_DAVAIL</b> | Indicates that data is available for this link address; the data must be read before any write can occur. |
| <b>WDI_COMM</b>   | Indicates a communication error. The <b>io_status</b> field contains the corresponding message code.      |
| <b>WDI_PROG</b>   | Indicates a program error. The <b>io_status</b> field contains the corresponding message code.            |
| <b>WDI_MACH</b>   | Indicates a hardware error. The <b>io_status</b> field contains the corresponding message code.           |

#### **ioctl Subroutine in DFT Mode**

The **ioctl** subroutine may be issued to the device handler when it is in DFT mode. The following are the available **ioctl** operations:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IOCINFO</b>   | Returns the logical terminal number. This number is the EBCDIC representation of the controller type and the controller attachment protocol in the <b>iocinfo</b> structure.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>WDC_AUTO</b>  | Valid only for non-SNA DFT mode. Provides the handler with the option to automatically acknowledge the receipt of a valid 3270 data stream. An acknowledgment is sent only if the beginning of the 3270 data stream consists of 0xF3 00 06 40 00 F1 C2 xx xx 10 14, where the xx fields are not examined. This command also allows the driver not to indicate acknowledgment upon receipt of data.                                                                                                                                                                                     |
| <b>WDC_INQ</b>   | Queries the status of the last non-SNA <b>read</b> or <b>write</b> call issued by the application. Also, the <b>WDC_INQ</b> operation determines if data is available for reading. The status is placed in the <b>io_flags</b> field of the <b>io3270</b> structure. This field accepts the following values:                                                                                                                                                                                                                                                                          |
|                  | <b>WDI_DAVAIL</b><br>Data is available for reading. The data is buffered either in the driver or in the communication adapter. The data should be read immediately to avoid its having an impact on performance.<br><br>In non-SNA DFT mode, a <b>write</b> or <b>writex</b> subroutine call cannot complete until the data has been read. In SNA DFT mode, the <b>WDI_DAVAIL</b> flag is used only to indicate that data is available when the device driver wakes up the application (if waiting on a <b>poll</b> or <b>select</b> call) after receiving data from the control unit. |
|                  | <b>WDI_COMM, WDI_PROG, or WDI_MACH</b><br>Indicates a communication check, program check, or machine check, respectively. In each of these cases, the <b>io_status</b> field contains a message code that specifies the type of check.                                                                                                                                                                                                                                                                                                                                                 |
|                  | <b>WDI_FATAL</b><br>Indicates that an error has occurred that prevents further communication between the application and the device driver, typically a coax disconnect or adapter failure. This flag may be set in conjunction with the <b>WDI_COMM</b> , <b>WDI_PROG</b> , or <b>WDI_MACH</b> flag. If the communications failure was caused by a coax disconnect, the <b>io_status</b> field contains a value of <b>WEB_610</b> .                                                                                                                                                   |
|                  | <b>WDI_WCUS_30</b><br>A communications check reminder that occurs when there is a network failure and the control unit is still communicating with the communication adapter. The specific type of error is contained in the <b>io_status</b> field as a 5XX error code. The communications check reminder is cleared automatically after the network condition is corrected.                                                                                                                                                                                                          |
|                  | <b>WDI_WCUS_31</b><br>Indicates that the communications check reminder has been cleared.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                  | <b>WDI CU</b><br>Valid only for SNA DFT mode. Indicates that an <b>ACTLU</b> or <b>DACTLU</b> request was received by the device driver. The accompanying data is contained in the <b>io_extra</b> field of the <b>io3270</b> structure.                                                                                                                                                                                                                                                                                                                                               |
| <b>WDC_POR</b>   | The link address is first disabled and then re-enabled to emulate a 3270 terminal power-on reset function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>WDC_SSTAT</b> | Valid only for non-SNA DFT mode. Sends status to the host. The argument field contains one of the following values:<br><br><b>STAT_ACK</b><br>The previously received 3270 data stream is valid, and the proper response is made to the host.<br><br><b>STAT_RESET</b><br>Sends a RESET Key to the DFT device handler.<br><br><b>STAT_PRTCMP</b><br>The printer session has completed printing the data.<br><br><b>STAT_BERR</b><br>Received a bad buffer order or an invalid buffer address.<br><br><b>STAT_UNSUP</b><br>Received an unsupported 3270 command.                        |
|                  | The <b>/usr/include/sys/io3270.h</b> file contains the definitions of the structures used by the device handler.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Error Conditions in DFT Mode

The following error conditions may be returned when accessing the device handler through the **3270cn** special file:

| Item   | Description                                                         |
|--------|---------------------------------------------------------------------|
| EBUSY  | An open was requested for a channel that is already open.           |
| EFAULT | A buffer specified by the caller was not valid.                     |
| EINTR  | A subroutine call was interrupted.                                  |
| EINVAL | An invalid argument was received.                                   |
| EIO    | An unrecoverable I/O error occurred on the requested data transfer. |
| ENODEV | An open was requested for an invalid channel.                       |
| ENOMEM | The driver could not allocate memory for use in the data transfer.  |
| ENXIO  | An operation was requested for an invalid minor device number.      |

### read Subroutine in CUT Mode

The **read** subroutine places data received by the communication adapter in a buffer.

**Note:** To set the offset into the communication adapter's buffer from which to read, use the **EMSEEK** ioctl operation.

Two ioctl operations control the way the **read** subroutine operates: the **EMNWAIT** and **EMWAIT** operations. The **EMNWAIT** operation indicates that subsequent read calls should be satisfied immediately. The **EMWAIT** ioctl operation (the default) indicates that read calls should be satisfied only after an interrupt from the control unit indicates that something has changed on the display. The following are control unit interrupts:

| Item                             | Description                                                        |
|----------------------------------|--------------------------------------------------------------------|
| Buffer Modification Complete     | The <b>read</b> subroutine returns the number of bytes requested.  |
| Load I/O Address Command Decoded | The <b>read</b> subroutine returns 0 for the number of bytes read. |

### write Subroutine in CUT Mode

The **write** subroutine sends an inbound 3270 data stream to the host. The buffer specified on a **write** subroutine must contain a complete inbound 3270 data stream. To set the offset into the communication adapter buffer to begin to write, use the **EMSEEK** ioctl operation.

### ioctl Subroutine in CUT Mode

The **ioctl** subroutine may be issued to the device handler in CUT mode. The following are acceptable **ioctl** operations:

| Item    | Description                                                                                                                                                                                                                                                                                                        |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EMKEY   | Sends a scancode to the emulation adapter. The scan code is logically ORed with the <b>EMKEY</b> operation, and the result is used as the command field on the <b>ioctl</b> subroutine call.                                                                                                                       |
| EMCPOS  | Returns the position of the cursor relative to the start of the communication adapter buffer.                                                                                                                                                                                                                      |
| EMXPOR  | Disables the link address and then re-enables it to emulate a 3270 terminal power-on reset function.                                                                                                                                                                                                               |
| EMNWAIT | Specifies that <b>read</b> subroutine calls should be satisfied immediately.                                                                                                                                                                                                                                       |
| EMWAIT  | Specifies that <b>read</b> subroutine calls should be satisfied only after a change to the emulation buffer or the cursor position (this is the default setting).                                                                                                                                                  |
| EMVISND | Returns the current contents of the emulation Visual/Sound register in the <b>integer</b> field. The address of this field is specified as the argument to the <b>EMVISND</b> operation.                                                                                                                           |
| EMIMASK | Provides a mask to specify which interrupts appear. The argument field specifies the address of the mask. The low-order bits of the mask (0 through 7) correspond to bits 0 through 7 of the Interrupt Status register. Bits 8 through 15 of the mask correspond to bits 0 through 7 of the Visual/Sound register. |

This operation allows the driver to ignore visual or sound interrupts except for those bits specifically masked ON. When a bit is on, the interrupt that corresponds to that bit position appears. Interrupts that correspond to off (0) bit positions in the mask are discarded by the device handler. The previous mask setting is returned to the caller in the **mask** field. The interrupt status bits and the visual or sound bits are documented in the *IBM 3270 Connection Technical Reference*.

| Item           | Description                                                                                                                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IOCINFO</b> | Returns a structure of device information, as defined in the <code>/usr/include/sys/devinfo.h</code> file, to the user-specified area. The <code>devtype</code> field has a value of <b>DD_EM78</b> , which is defined in the <code>devinfo.h</code> file, and the <code>flag</code> field value has a value of 0. |
| <b>EMSEEK</b>  | Sets the offset into the communication adapter buffer to begin a <b>read</b> or <b>write</b> subroutine call.                                                                                                                                                                                                      |

### Error Conditions in CUT Mode

The following error conditions may be returned when accessing the device handler through the `dev/3270cn` special file:

| Item              | Description                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EBUSY</b>      | An open was requested for a channel that is already open. The keystroke buffer is full.                                                                |
| <b>EFAULT</b>     | A buffer specified by the caller is not valid.                                                                                                         |
| <b>EINTR</b>      | A subroutine call was interrupted.                                                                                                                     |
| <b>EINVAL</b>     | An invalid argument was specified on an <b>ioctl</b> call.                                                                                             |
| <b>EL3RST</b>     | A <b>reset</b> command was received by the communications adapter.                                                                                     |
| <b>ENOCONNECT</b> | The connection to the control unit stopped while a <b>read</b> operation, for which the <b>EMWAIT</b> ioctl operation had been specified, was waiting. |
| <b>EIO</b>        | An unrecoverable I/O error occurred on the requested data transfer.                                                                                    |
| <b>ENXIO</b>      | An operation was requested for a minor device number that is not valid.                                                                                |

This special file requires the IBM 3270 Connection Adapter.

## bus Special File

### Purpose

Provides access to each of the hardware buses by way of the machine I/O device driver.

### Description

The **bus** special files consist of a pseudo-driver in the kernel that allows a privileged user to access each hardware I/O bus. This is done indirectly by using the **ioctl** subroutine. The calling process, however, must have the appropriate system privilege to open the **bus** special files.

For additional information on **bus** special files, see device configuration documentation in *Kernel Extensions and Device Support Programming Concepts* and machine device driver documentation in *Technical Reference: Kernel and Subsystems, Volume 1*.

This capability should be used only by device initialization and configuration programs. Programs that depend upon the **bus** device interface may not be portable to machines with different hardware.

There is at least one **bus** special file, usually the `/dev/pci0` or the `/dev/bus0` special file. This file accesses the primary hardware bus. One **bus** special file exists for each hardware bus on the machine. Each **bus** special file gains access to the corresponding hardware bus, and exists only if the hardware bus is present or was present at one time. Run the following command to generate a list of all the defined **bus** special files for a machine:

```
lsdev -C -c bus -F name | xargs -i echo
/dev/{}{}
```

Machine Device Driver

## **cd Special File**

### **Purpose**

Provides access to the CD-ROM device driver.

### **Description**

The CD-ROM special file provides block and character (raw) access to disks in the CD-ROM drives.

The **r** prefix on a special file name means the drive is accessed as a raw device rather than a block device. Performing raw I/O with a compact disk requires the performance of all data transfers in multiples of the compact-disk logical block length. Also, all **Iseek** subroutines made to the raw CD-ROM device driver must set the file offset pointer to a value that is a multiple of the specified logical block size.

### **CD-ROM Device Drivers**

Compact disks, used in CD-ROM device drivers, are read-only media that provide storage for large amounts of data. The special files **/dev/cd0**, **/dev/cd1**,... provide block access to compact disks. The special files **/dev/rcd0**, **/dev/rc1**,... provide character access.

When a CD-ROM disc is ejected from the drive for a mounted CD-ROM file system, the files on the compact disc can no longer be accessed. Before these files can be accessed again, the file systems mounted from the CD-ROM must be unmounted. Processes having files open on these file systems should be exited. Processes having current directories on these file systems should be moved. If these actions do not work, perform a forced unmount.

Another problem that results from ejecting the CD-ROM disc for a mounted CD-ROM file system is that the **man** command can become unresponsive. Reinserting the CD-ROM disc will not fix the problem. All processes (graphical and ASCII) should be exited and the file system should be forced unmounted and mounted again. Afterwards, any **man** commands can be started again.

### **Device-Dependent Subroutines**

Most CD-ROM operations are implemented using the **open**, **read**, and **close** subroutines. However, for some purposes, use of the **openx** (extended) subroutine is required.

| Item                    | Description                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>openx Subroutine</b> | The <b>openx</b> subroutine is supported to provide additional functions to the open sequence. The <b>openx</b> subroutine requires appropriate authority to start. Attempting to execute this subroutine without the proper authority results in a return value of -1, with the <b>errno</b> global variable set to <b>EPERM</b> .                                        |
| <b>ioctl Subroutine</b> | The <b>IOCINFO</b> ioctl operation is defined for all device drivers that use the <b>ioctl</b> subroutine. The remaining ioctl operations are all physical volume device-specific operations. Diagnostic mode is not required for the following operation. The <b>IOCINFO</b> operation returns a <b>devinfo</b> structure, which is defined in the <b>devinfo.h</b> file. |

### **Error Codes**

In addition to the error codes listed for the **ioctl**, **open**, **read**, and **write** subroutines, the following error codes are also possible:

| Item      | Description                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------|
| EACCES    | A subroutine other than <b>ioctl</b> or <b>close</b> was attempted while in Diagnostic mode.                                   |
| EACCES    | A normal <b>read</b> call was attempted while in Diagnostic mode.                                                              |
| EFAULT    | Illegal user address.                                                                                                          |
| EBUSY     | The target device is reserved by another initiator.                                                                            |
| EINVAL    | The device was opened with a mode other than read-only.                                                                        |
| EINVAL    | An <i>nbyte</i> parameter to a <b>read</b> subroutine is not an even multiple of the block size.                               |
| EINVAL    | A sense-data buffer length greater than 255 is not valid for a <b>CDIOCMD</b> ioctl operation.                                 |
| EINVAL    | A data buffer length greater than that allowed by the drive is not valid for a <b>CDIOCMD</b> ioctl operation.                 |
| EINVAL    | An attempt was made to configure a device that is still open.                                                                  |
| EINVAL    | An illegal configuration command has been given.                                                                               |
| EMFILE    | An <b>open</b> call has been attempted for a SCSI adapter that already has the maximum permissible number of open devices.     |
| ENOTREADY | There is no compact disk in the drive.                                                                                         |
| ENODEV    | An attempt was made to access a device that is not defined.                                                                    |
| ENODEV    | An attempt was made to close a device that has not been defined.                                                               |
| EMEDIA    | The media was changed.                                                                                                         |
| EIO       | Hardware error or aborted command or illegal request.                                                                          |
| EIO       | An attempt has been made to read beyond the end of media.                                                                      |
| EPERM     | This subroutine requires appropriate authority.                                                                                |
| ESTALE    | A CD-ROM disk was ejected (without first being closed by the user) and then either re-inserted or replaced with a second disk. |
| ETIMEDOUT | An I/O operation has exceeded the given timer value.                                                                           |

## console Special File

### Purpose

Provides access to the system console.

### Description

The **/dev/console** special file provides access to the device or file designated as the system console. This file can be designated as the console device by the person administering the system or a user with the appropriate permissions. The **console** character special file provides access to the console device driver. The console device driver in turn directs input and output to the device or file selected as the system console.

The system console is typically a terminal or display located near the system unit. It has two functions in the operating system. First, it provides access to the system when it is operating in a non-multiuser mode. (This would be the case during maintenance and diagnostic sessions.) A console login is also normally provided on this device for all operating system run levels.

Second, the system console displays messages for system errors and other problems requiring intervention. These messages are generated by the operating system and its various subsystems when starting or operating. The system console can also be redirected to a file or to the **/dev/null** special file for systems operating without a console device.

### Console Driver Configuration Support

Console driver configuration support allows the system console to be assigned or reassigned to a specified device or file. Such support also provides query functions to determine the current and configured path names for the device or file designated as the console. This configuration support is used by the **swcons**, **chcons**, and **lsccons** high-level system management commands. It is also used by the console configuration method at system startup.

The **swcons** (switch console) command can be used during system operation to switch the system console output to a different target temporarily. This command switches only system information, error, and intervention-required messages to the specified destination. The **swcons** command does not affect the operation of the system console device that provides a login through the **getty** command. The device or file specified when using the **swcons** command remains the target for console output until one of the following happens:

- Another **swcons** command is issued.
- The system is started again.
- The console driver detects an error when accessing the designated device or file.

If an open or write error is detected on the device or file specified by the **swcons** command, the console device driver switches all output back to the device or file providing console support when the system started.

The **chcons** (change console) command can be used to switch the system console output to a different device or file for the next startup. This command does not affect the current console selection, but becomes effective when the system is started again.

When requested to activate a login on the console device, the **getty** program (which provides login support) uses the console configuration support to determine the path name of the targeted console device used at startup. This action ensures that the **swcons** command does not effect the console device being used for login.

## Usage Considerations

The **open**, **close**, **read**, **write**, **ioctl**, **select**, and **poll** subroutines are supported by the console device driver and may be used with the **/dev/console** special file. These subroutines are redirected to the device or file serving as the current system console device by the console device driver.

### open and close Subroutines

When an **open** subroutine call is issued to the console device driver, it is redirected to the device or file currently chosen as the console device. If the system console choice is a file, the file is opened with the *append* and *create* options when the first open of the **dev/console** file is received. Subsequent opens have no effect when the console selection is a file. However, the opens are then passed to the device driver supporting the device chosen as the console.

If the console selection has been temporarily switched using the **swcons** command and the first open of the new underlying device fails, the console device driver switches back to the console device or file with which the system was booted. This prevents important system messages from being lost.

An *ext* parameter passed using the **openx** subroutine is passed to the device driver supporting the console target or else ignored. (The latter is true if the console selection is a file.)

The **close** subroutine support is standard.

### select, poll, and ioctl Subroutines

The **select**, **poll**, and **ioctl** subroutines are redirected to the current system console device when the console selection is not a file. If the selected console device is a file, the console device driver returns an error indicating that the subroutine is not supported.

An *ext* parameter passed to the **ioctlx** subroutine is then passed to the device driver supporting the console target, or else ignored. (The latter is true if the console selection is a file.)

### **read and write Subroutines**

The **write** subroutine calls are redirected to the current console device or file. If the console selection has been temporarily switched using the **swcons** command, and the write to the targeted device or file is unsuccessful, the console device driver switches back to the console device or file from which the system was started and tries the write again. This prevents important system messages from being lost in case the temporary console target is unavailable or unsuccessful. The console device driver should stay connected to the original system device until another **swcons** command is issued.

If the current console selection is a device, it redirects the **read** subroutine call. If the current console selection is a file, the **read** call is rejected with an error (EACCES).

An *ext* parameter passed to the **readx** or **writex** subroutine is passed to the device driver supporting the console target, or else ignored. (The latter is true if the console selection is a file.)

**Note:** The EIO errors resulting from the console write function are restricted. Because when a tty attached to a modem gets disconnected, the streams file is marked. The console redirects any writes to the console to where the console points to. Then, any writes to the file descriptor are returned with EIO errors. These EIO errors continue until some process reopens the console. Therefore, the EIO errors are restricted in certain situation when the connection to the console is lost.

## **Console Output Logging**

All output sent to the console is logged to a system log file. Only output sent to the console is logged. Any output sent to a device acting as the console is not logged. This means that system informational, error, and intervention-required messages are captured (logged), while other types of output seen at the console are not; e.g., getty output, smitty output, user interaction at the console device, etc.

The log file is based on the **alog** format; this format allows the file to wrap after it attains a predetermined maximum size. The **alog** command is typically used to view the console log file. The console log file deviates from the normal alog format in that each record of the file contains, in addition to the logged text, the user id who wrote to the console and the epoch time when it was written. The epoch time is formatted and displayed in the user's locale date and time when the file is output by the **alog** command.

When the console device is configured or when any modification is made to the console log file, ownership of the file is set to root and permissions are set to 620. The root user can modify the ownership or permissions, but they will not persist across boots.

The **swcons** command is used to make changes to console logging parameters during system operation; these changes are rescinded at the next console device configuration (typically reboot), and the original console logging parameters are reinstated.

The **chcons** command is used to make changes to the console logging parameters for the next console device configuration (typically reboot). These changes do not apply to the current running system.

The console logging facility can also be configured using the **alog** command. When the **alog -C** flag is used, changes are effective in the current running system and are persistent across boots. When the **-S**

flag is used (without) the **-C**) to change the file size, the file is changed immediately but this change is not saved in the ODM and is not persistent across boots.

The parameters that control the console logging facility are the pathname of the log file, the maximum size of the log file, and the verbosity index for logging. Restrictions on these parameters are:

- the log file path must be absolute
- the maximum file size must not exceed the current free space of the file system on which it is stored (and the user entered value is rounded up to the nearest 4K boundary)
- verbosity values are 0-9 with any value greater than 0 indicating that all console output is to be recorded.

## Console Output Tagging

A facility is provided to prefix each console output message with the effective user ID of the user that sent the message to the console. Only output sent to the console is tagged, any output sent to the device acting as the console is not.

Both the **swcons** command and the **chcons** commands can be used to enable and disable console output tagging with the same caveats about the persistence of the values applying as mentioned above in Console Output Logging.

The console output tagging verbosity value is limited to the range 0-9. Any value greater than 0 causes all console output to be tagged.

## Console Special File Limitation

The Error Input/Output (EIO) errors are restricted in some cases when the connection to the console is lost. The EIO errors that result from the console write function are restricted because the streams file is marked when a **tty** device that is connected to a modem is disconnected. All write operations to the console are redirected to where the console points and writes operation to the file descriptor are returned with EIO errors. These EIO errors continue until a process reopens the console.

## Files

| Item                   | Description                         |
|------------------------|-------------------------------------|
| <code>/dev/null</code> | Provides access to the null device. |

**getty** command  
**lscons** command  
**swcons** command

## dials Special File

### Purpose

Provides access to the dials.

### Description

The **dials** special file is the application interface to the dials. It allows the applications to receive operator input from the dials and to set the granularity of the dials.

## Configuration

Standard configuration methods are provided for the **dials** special file. The user cannot enter configurable attributes by way of the command line.

## Usage Considerations

### open

An **open** subroutine call specifying the **dials** special file is processed normally except that the *Oflag* and *Mode* parameters are ignored. An open request is rejected if the special file is already opened or if a kernel extension attempts to open the **dials** special file. All dials inputs are flushed following an open call until an input ring is established.

### read and write

The **dials** special file does not support read or write subroutine calls. Input data is obtained from the dials via the input ring. The read and write subroutine calls behave the same as read or write to **/dev/null**. See "LFT Input Ring" in *Kernel Extensions and Device Support Programming Concepts* for how to use the input ring.

### ioctl

The dials special file supports the following **ioctl** operations:

| Item         | Description                           |
|--------------|---------------------------------------|
| IOCINFO      | Returns the <b>devinfo</b> structure. |
| DIALREGRING  | Registers input ring.                 |
| DIALRFLUSH   | Flushes input ring.                   |
| DIALSETGRAND | Sets dial granularity.                |

## Error Codes

The error codes can be found in the **/usr/include/sys/errno.h** file.

| Item   | Description                                                            |
|--------|------------------------------------------------------------------------|
| EFAULT | Indicates insufficient authority to access address or invalid address. |
| EIO    | Indicates I/O error.                                                   |
| ENOMEM | Indicates insufficient memory for required paging operation.           |
| ENOSPC | Indicates insufficient file system or paging space.                    |
| EINVAL | Indicates invalid argument specified.                                  |
| EINTR  | Indicates request interrupted by signal.                               |
| EPERM  | Indicates a permanent error occurred.                                  |
| EBUSY  | Indicates device busy.                                                 |
| ENXIO  | Indicates unsupported device number.                                   |
| ENODEV | Indicates unsupported device or device type mismatch.                  |

## Files

| Item                       | Description                                                            |
|----------------------------|------------------------------------------------------------------------|
| /usr/include/sys/inputdd.h | Contains declarations for ioctl commands and input ring report format. |

## **dump Special File**

### **Purpose**

Supports system dump.

### **Syntax**

```
#include <sys/dump.h>
```

### **Description**

The **/dev/sysdump** and **/dev/sysdumpctl** special files support system dumping. Minor device 0 of the **sysdump** driver provides the interfaces for the system dump routine to write data to the dump device. The **sysdump** driver also provides interfaces for querying or assigning the dump devices and initiating a dump.

## **entn Special File**

### **Purpose**

Provides access to Ethernet high-performance LAN adapters by way of the Ethernet device handler.

### **Description**

The **/dev/entn** character special file provides access to the Ethernet device handler for the purpose of providing access to an Ethernet LAN. The device handler supports up to four adapters, each of which may be running either or both of the standard Ethernet and IEEE 802.3 protocols.

### **Usage Considerations**

When accessing the Ethernet device handler, the following should be taken into account:

#### **Driver Initialization and Termination**

The device handler can be loaded and unloaded. The handler supports the configuration calls to initialize and terminate itself.

#### **Special File Support**

Calls other than the **open** and **close** subroutines are discussed based on the mode in which the device handler is operating.

## Subroutine Support

The Ethernet device handler supports the **open** and **close**, **read**, and **write** subroutines in the following manner:

### open and close Subroutines

The device handler supports the **/dev/entn** special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). However, there are no particular considerations for closing the special file. The special file name used in an **open** call depends upon how the device is to be opened. Types of special file names are:

| Item               | Description                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>/dev/entn</b>   | An <b>open</b> call to this device is used to start the device handler for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ .                    |
| <b>/dev/entn/D</b> | An <b>open</b> call to this device is used to start the device handler for the selected port in diagnostic mode, where the value of <i>n</i> is $0 \leq n \leq 7$ . |

### read Subroutine

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine. For this call, the device handler copies the data into the buffer specified by the caller.

### write Subroutine

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine. For this call, the device handler copies the user data into a buffer and transmits the data on the LAN.

## Error Codes

The following error codes may be returned when accessing the device handler through the **dev/entn** special file:

| Item                | Description                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EACCES</b>       | Permission to access the port is denied for one of the following reasons: <ul style="list-style-type: none"><li>• The device has not been initialized.</li><li>• The request to open the device in Diagnostic mode is denied.</li><li>• The call is from a kernel mode process.</li></ul> |
| <b>EAFNOSUPPORT</b> | The address family is not supported by the protocol, or the multicast bit in the address is not set.                                                                                                                                                                                      |
| <b>EAGAIN</b>       | The transmit queue is full.                                                                                                                                                                                                                                                               |
| <b>EBUSY</b>        | The request is denied because the device is already opened in Diagnostic mode, or the maximum number of opens was reached.                                                                                                                                                                |
| <b>EEXIST</b>       | The define device structure (DDS) already exists.                                                                                                                                                                                                                                         |
| <b>EFAULT</b>       | An address or parameter was specified that is not valid.                                                                                                                                                                                                                                  |
| <b>EINTR</b>        | A subroutine call was interrupted.                                                                                                                                                                                                                                                        |
| <b>EINVAL</b>       | A range or operation code that is not valid was specified, or the device is not in Diagnostic mode.                                                                                                                                                                                       |
| <b>EIO</b>          | An I/O error occurred.                                                                                                                                                                                                                                                                    |
| <b>ENOBUFS</b>      | No buffers are available.                                                                                                                                                                                                                                                                 |
| <b>ENOCONNECT</b>   | A connection was not established.                                                                                                                                                                                                                                                         |
| <b>ENODEV</b>       | The device does not exist.                                                                                                                                                                                                                                                                |
| <b>ENOENT</b>       | There is no DDS to delete.                                                                                                                                                                                                                                                                |
| <b>ENOMEM</b>       | The device does not have enough memory.                                                                                                                                                                                                                                                   |
| <b>ENOMSG</b>       | No message of desired type was available.                                                                                                                                                                                                                                                 |
| <b>ENOSPC</b>       | No space is left on the device (the multicast table is full).                                                                                                                                                                                                                             |

| Item      | Description                                                                                                             |

## Error Logging Special Files

### Purpose

Support error logging.

### Description

The **error** and **errorctl** special files support the logging of error events. Minor device 0 (zero) of the **error** special file is the interface between processes that log error events and the **errdemon** (error daemon). Error records are written to the **error** special file by the **errlog** library routine and the **errsave** and **errlast** kernel services. The **error** special file timestamps each error record entry.

The error daemon opens **error** file for reading. Each read retrieves an entire error record. The format of error records is described in the **erec.h** header file.

Each time an error is logged, the error ID, the resource name, and the time stamp are recorded in nonvolatile random access memory (NVRAM). Therefore, in the event of a system crash, the last logged error is not lost. When the **error** file is restarted, the last error entry is retrieved from NVRAM.

The standard device driver interfaces (open, close, read, and write) are provided for the **error** file. The **error** file has no **ioctl** functions.

The **ioctl** function interface for the **error** special file is provided by the **errorctl** special file. This interface supports stopping the error logging system, synchronizing the error logging system, and querying the status of the error special file.

## fd Special File

### Purpose

Provides access to the diskette device driver.

## Description

The **fd** special file provides block and character (raw) access to diskettes in the diskette drives. The special file name usually specifies both the drive number and the format of the diskette. The exceptions are **/dev/fd0** and **/dev/fd1**, which specify diskette drives 0 and 1, respectively, without specifying their formats.

The generic special files **/dev/fd0** and **/dev/fd1** determine the diskette type automatically for both drive 0 and drive 1. First, the device-driver attempts to read the diskette using the characteristics of the default diskette for the drive type. If this fails, the device-driver changes its characteristics and attempts to read until it has read the diskette successfully or until it has tried all the possibilities supported for the drive type by the device driver.

An **r** prefix on a special file name means that the drive is accessed as a raw device rather than a block device. Performing raw I/O with a diskette requires that all data transfers be in multiples of the diskette sector length. Also, all **Iseek** subroutine calls made to the raw diskette device driver must result in a file offset value that is a multiple of the sector size. For the diskette types supported, the sector length is always 512 bytes.

**Note:** The diskette device driver does not perform read verification of data that is written to a diskette.

### Types of Diskettes Supported

The **fd** special file supports three diskette drives: the 1.2MB, 5.25-inch diskette drive, and the 1.44MB and 2.88MB, 3.5-inch diskette drives. All **fd** special file names (except the generic special files **/dev/fd0**, **/dev/fd1**, **/dev/rfd0**, and **/dev/rfd1**) contain suffixes that dictate how a diskette is to be treated. These special file names have a format of *PrefixXY*, where the *Prefix*, *X*, and *Y* variables have the following meanings:

| Item          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>Prefix</i> | Special file type. Possible values are <b>fd</b> and <b>rfd</b> , where the <b>r</b> indicates raw access to the special file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>X</i>      | Drive number indicator. Possible values of <b>0</b> and <b>1</b> indicate drives 0 and 1, respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>Y</i>      | Diskette format indicator. Possible values depend on the type of diskette being used. Either a single character or a decimal point followed by numeric characters is allowed. Possible values are: <ul style="list-style-type: none"><li><b>h</b> Highest density supported by the drive type</li><li><b>l</b> Lowest density supported by the drive type</li><li><b>.9</b> 9 sectors per track (all three drive types)</li><li><b>.15</b> 15 sectors per track (1.2MB, 5.25-inch drive only)</li><li><b>.18</b> 18 sectors per track (both 3.5-inch drive types)</li><li><b>.36</b> 36 sectors per track (2.88MB, 3.5-inch drive only)</li></ul> |

### 1.44MB, 3.5-inch Diskette Special Files

Ten different special files are available for use with the 1.44MB, 3.5-inch diskette drive. The default diskette type assumed for this drive type is a double-sided, 80-cylinder, 18 sectors-per-track diskette.

An **h** or **.18** as the suffix of the special file name (for example, **/dev/rfd0h** or **/dev/fd0.18**) forces a diskette to be treated as a double-sided, 80-cylinder, 18 sectors-per-track diskette. An **l** or **.9** as the suffix of the special file name (for example, **/dev/fd1l** or **/dev/rfd0.9**) forces a diskette to be treated as a double-sided, 80-cylinder, 9 sectors-per-track diskette.

### 2.88MB, 3.5-inch Diskette Special Files

Twelve different special files are available for use with the 2.88MB, 3.5-inch diskette drive. The default diskette type assumed for this drive type is a double-sided, 80-cylinder, 36 sectors-per-track diskette.

An **h** or **.36** as the suffix of the special file name (for example, /dev/fd1h or /dev/fd0.36) forces a diskette to be treated as a double-sided, 80-cylinder, 36 sectors-per-track diskette. An **1** or **.9** as the suffix of the special file name (for example, /dev/rfd01 or /dev/fd1.9) forces a diskette to be treated as a double-sided, 80-cylinder, 9 sectors-per-track diskette. A suffix of **.18** (for example, /dev/fd1.18) forces a diskette to be treated as a double-sided, 80-cylinder, 18-sectors-per-track diskette.

### 1.2MB, 5.25-inch Diskette Special Files

Ten different special files are available for use with the 1.2MB, 5.25-inch diskette drive. The default diskette type assumed for this drive type is a double-sided, 80-cylinder, 15 sectors-per-track diskette.

An **h** or **.15** as the suffix of the special file name (for example, /dev/rfd1h or /dev/fd0.15) forces a diskette to be treated as a double-sided, 80-cylinder, 15 sectors-per-track diskette. An **1** or **.9** as the suffix of the special file name (for example, /dev/fd01 or /dev/rfd1.9) forces a diskette to be treated as a double-sided, 80-cylinder, 9 sectors-per-track diskette.

**Note:** Regardless of the diskette drive type, an **h** as the suffix of the special file name forces a diskette to be treated as the highest capacity diskette supported by the drive type. When an **1** is used as the suffix of the special file name, the diskette is treated as the lowest capacity diskette supported by the drive type.

### Usage Considerations

When using subroutines with the **fd** special file, consider the following items:

| Item                              | Description                                                                                                                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>open and close subroutines</b> | Only one process at a time can issue an <b>open</b> subroutine to gain access to a particular drive. However, all child processes created by a parent process that successfully opens a diskette drive inherit the open diskette drive. |
| <b>read and write subroutines</b> | No special considerations.                                                                                                                                                                                                              |

| Item                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ioctl subroutines</b> | The possible ioctl operations and their descriptions are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>IOCINFO</b>           | Returns a <b>devinfo</b> structure (defined in the <b>/usr/include/sys/devinfo.h</b> file) that describes the device.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>FDIOCSINFO</b>        | Sets the characteristics of the device driver diskette to the values passed in the <b>fdinfo</b> structure, as defined in the <b>/usr/include/sys/fd.h</b> file.                                                                                                                                                                                                                                                                                                                                                          |
| <b>FDIOCGINFO</b>        | Gets the device-driver diskette characteristics and returns the values in the <b>fdinfo</b> structure, as defined in the <b>/usr/include/sys/fd.h</b> file.                                                                                                                                                                                                                                                                                                                                                               |
| <b>FDIOCFORMAT</b>       | Formats a diskette track. The diskette is formatted using data passed in an array of bytes. The length of this array is four times the number of sectors per track on the diskette. The reason for this is that 4 bytes of data must be passed in for every sector on the track. The 4 bytes contain, in this order, the cylinder number, the side number (0 or 1), the sector number, and the number of bytes per sector. This pattern must be repeated for every sector on the track.                                   |
|                          | The diskette characteristics used during formatting are whatever values are in the device driver when it receives the format command. These characteristics need to be set to the desired values prior to issuing the <b>format</b> command. There are three ways to do this:                                                                                                                                                                                                                                             |
|                          | <ul style="list-style-type: none"> <li>• Open the diskette driver using one of the format-specific special files. As a result, the diskette characteristics for the driver will be those of the diskette indicated by the special file.</li> <li>• Open the diskette driver using one of the generic special files. In this case, the diskette characteristics will be the default characteristics for that driver.</li> <li>• Set the characteristics explicitly using the <b>FDIOCSINFO</b> ioctl operation.</li> </ul> |

For formatting, the diskette driver should be opened only when the **O\_NDELAY** flag is set. Otherwise, the driver will attempt to determine the type of diskette in the drive, causing the open to fail.

## fddin Special File

### Purpose

Provides access to the FDDI device driver by way of the FDDI device handler.

### Description

The **fddin** special file provides access to the FDDI device handler that provides access to a FDDI local area network.

When accessing the FDDI device driver, the following information should be taken into account.

## Driver Initialization and Termination

The device driver can be loaded and unloaded. The device driver supports the configuration calls to initialize and terminate itself.

## Special File Support

Subroutine calls other than those made with the **open** and **close** subroutines are discussed based on the mode in which the device driver is operating.

## Subroutine Support

The FDDI device driver provides specific support for the **open**, **close**, **read**, **write**, **ioctl**, **select**, and **poll** subroutines.

The device driver supports the **/dev/fddin** special file as a character-multiplex special file. The special file must be opened for both reading and writing. There are no particular considerations for closing the special file. The special file name used in an open call differs depending upon how the device is to be opened. Types of special file names are:

| Item                | Description                                                                      |
|---------------------|----------------------------------------------------------------------------------|
| <b>/dev/fddin</b>   | Starts the device driver for the selected port.                                  |
| <b>/dev/fddin/D</b> | Starts the device driver for the selected port in Diagnostic mode.               |
| <b>/dev/fddin/C</b> | Starts the device driver for the selected port in Diagnostic Configuration mode. |

## Error Codes

The following error conditions may be encountered when accessing the FDDI device driver through the **/dev/fddin** special file. The error codes can be found in the **/usr/include/sys/errno.h** file.

| Item               | Description                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ENODEV</b>      | Indicates that an invalid minor number was specified.                                                                                                                                                                                                    |
| <b>EINVAL</b>      | Indicates that an invalid parameter was specified.                                                                                                                                                                                                       |
| <b>ENOMEM</b>      | Indicates that the device driver was unable to allocate the required memory.                                                                                                                                                                             |
| <b>EINTR</b>       | Indicates that a system call was interrupted.                                                                                                                                                                                                            |
| <b>EPERM</b>       | Indicates that the Diagnostic mode open request was denied because the device was already open.                                                                                                                                                          |
| <b>EACCES</b>      | Indicates one of the following: <ul style="list-style-type: none"><li>• A non-privileged user tried to open the device in Diagnostic mode.</li><li>• An illegal call from a kernel-mode user.</li><li>• An illegal call from a user-mode user.</li></ul> |
| <b>ENETDOWN</b>    | Indicates one of the following: <ul style="list-style-type: none"><li>• The network is down. The device is unable to process the requested operation.</li><li>• An unrecoverable hardware error.</li></ul>                                               |
| <b>ENETUNREACH</b> | Indicates that the device is in Network Recovery mode and is unable to process the requested operation.                                                                                                                                                  |
| <b>ENOCONNECT</b>  | Indicates that the device has not been started.                                                                                                                                                                                                          |
| <b>EAGAIN</b>      | Indicates that the transmit queue is full.                                                                                                                                                                                                               |
| <b>EFAULT</b>      | Indicates that an invalid address was supplied.                                                                                                                                                                                                          |
| <b>EIO</b>         | Indicates an error. See the status field for detailed information.                                                                                                                                                                                       |
| <b>EMSGSIZE</b>    | Indicates that the data was too large to fit into the receive buffer and that no <i>ext</i> parameter was supplied to provide an alternate means of reporting this error with a status of <b>CIO_BUF_OVFLW</b> .                                         |

# **GIO Special File**

## **Purpose**

Provides access to the graphics I/O (GIO) adapter.

## **Description**

The **GIO** special file is the application interface to the GIO adapter. The **GIO** special file provides applications with the ability to determine what I/O devices are attached to the GIO adapter.

## **Configuration**

Standard configuration methods are provided for the **GIO** special file. User configurable attributes for the **GIO** special file do not exist.

## **Usage Considerations**

The **open** subroutine call specifying the **GIO** special file is processed normally except that the *Oflag* and *Mode* parameters are ignored. An **open** request is rejected if the special file is already opened or if a kernel extension attempts to open the **GIO** special file.

Calls to the **read** and **write** routines behave as if the call was made to the **/dev/null** file.

The **GIO** special file supports the following functions with ioctl:

| Item              | Description                                                    |
|-------------------|----------------------------------------------------------------|
| <b>IOCINFO</b>    | Returns the <b>devinfo</b> structure.                          |
| <b>GIOQUERYID</b> | Returns the identifier of device connected to the GIO adapter. |

## **Error Codes**

The following error codes can be found in the **/usr/include/sys/errno.h** file:

| Item          | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>EFAULT</b> | Indicates insufficient authority to access address or invalid address. |
| <b>EIO</b>    | Indicates an I/O error.                                                |
| <b>ENOMEM</b> | Indicates insufficient memory for required paging operation.           |
| <b>ENOSPC</b> | Indicates insufficient file system or paging space.                    |
| <b>EINVAL</b> | Indicates that an invalid argument was specified.                      |
| <b>EINTR</b>  | Indicates a request interrupted by signal.                             |
| <b>EPERM</b>  | Indicates a permanent error occurred.                                  |
| <b>EBUSY</b>  | Indicates the device is busy.                                          |
| <b>ENXIO</b>  | Indicates an unsupported device number.                                |
| <b>ENODEV</b> | Indicates an unsupported device or device type mismatch occurred.      |

## **Files**

| Item                       | Description                  |
|----------------------------|------------------------------|
| /usr/include/sys/inputdd.h | Contains the ioctl commands. |

## ide Special File

### Purpose

Provides access to the Integrated Device Electronics (IDE) adapter driver.

### Description

The **ide** special file provides an interface to an attached IDE Bus. This special file should not be opened directly by application programs. The **/dev/ide0**, **/dev/ide1**, ... **/dev/iden** files are the **ide** special files.

**Related information:**

Integrated Device Electronics (IDE) Subsystem Overview  
 IDE Adapter Device Driver  
 idecdrom IDE CD-ROM Device Driver

## kbd Special File

### Purpose

Provides access to the natively attached keyboard.

### Description

The **kbd** special file is the interface to the native keyboard. It provides an interface through which applications can receive operator input from the keyboard, control the keyboard LED's, and changing various keyboard parameters. The special file also allows an application to send an audible signal to the operator via the speaker located within the keyboard.

### Configuration

The sound volume, click volume, typematic rate and typematic delay are configurable by the application through the **ioctl** subroutine. These changes are not reflected in the ODM database. To change these attributes in the ODM database, use the **chhwkbd** command.

### Usage Considerations

#### open

This subroutine call creates a channel between the application and the natively attached keyboard. Two channels are supported. The open subroutine call is processed normally except that the *MODE* and *Oflag* parameters are ignored. All keyboard input is flushed until an input ring is established. Only the input ring associated with the most recent open receives input reports.

## **close**

When the **kbd** device has been opened twice, input is reported through the input ring registered previous to the first **open**, after the **close** subroutine call.

## **read and write**

The keyboard device driver does not return nor accept data via **read** and **write**. These calls behave as if the call was made to **/dev/null**. Input data is received from the input drivers via the input ring.

## **ioctl**

The keyboard device driver supports the following ioctl commands:

| Item              | Description                                       |
|-------------------|---------------------------------------------------|
| <b>IOCINFO</b>    | Return <b>devinfo</b> structure.                  |
| <b>KSALARM</b>    | Sound alarm.                                      |
| <b>KSCFGCLICK</b> | Control keyboard click.                           |
| <b>KSDIAGMODE</b> | Enable/disable diagnostics mode (user mode only). |
| <b>KSLED</b>      | Set/reset keyboard LED's.                         |
| <b>KSKAP</b>      | Enable/disable keep alive poll (user mode only).  |
| <b>KSKAPACK</b>   | Acknowledge keep alive poll (user mode only).     |
| <b>KSQUERYID</b>  | Query keyboard device identifier.                 |
| <b>KSQUERYSV</b>  | Query keyboard service vector (kernel mode only). |
| <b>KSREGRING</b>  | Register input ring.                              |
| <b>KSRFLUSH</b>   | Flush input ring.                                 |
| <b>KSTDELAY</b>   | Set typematic delay.                              |
| <b>KSTRATE</b>    | Set typematic rate.                               |
| <b>KSVOLUME</b>   | Set alarm volume                                  |

## **Error Codes**

The error codes can be found in the **/usr/include/sys/errno.h** file.

| Item          | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>EFAULT</b> | indicates insufficient authority to access address or invalid address. |
| <b>EIO</b>    | indicates that an I/O error occurred.                                  |
| <b>ENOMEM</b> | indicates there was insufficient memory for required paging operation. |
| <b>ENOSPC</b> | indicates there was insufficient file system or paging space.          |
| <b>EINVAL</b> | indicates that an invalid argument was specified.                      |
| <b>EINTR</b>  | indicates the request was interrupted by signal.                       |
| <b>EPERM</b>  | indicates that a permanent error occurred.                             |
| <b>EBUSY</b>  | indicates the device is busy.                                          |
| <b>ENXIO</b>  | indicates unsupported device number was specified.                     |
| <b>ENODEV</b> | indicates an unsupported device or device type mismatch.               |

## Ift Special File

### Purpose

Provides character-based terminal support for the local graphics display and keyboard.

### Description

The **lft** file is the application interface to the "Low Function Terminal (LFT) Subsystem". It provides support for a VT100-like terminal which is associated with the local graphics display and keyboard. It provides only character operations and is designed to be used during system installation, startup, shutdown, and stand-alone diagnostics.

The terminal supports a single logical screen size of 80 characters and 25 lines and a single color. Dynamic Logical Partitioning is not supported, configuration changes take effect at the next system startup. In the cases when multiple fonts may be used to achieve the 80x25 screen size, the user may set which font is used with the next system restart. See "LFT User Commands" for details of the available commands.

When multiple displays are available, the LFT Subsystem initially uses the default display. The user may change to another display and set the default display. See "LFT User Commands" for details of the available commands.

### Usage Considerations

The LFT device driver supports the **lft** special file. The device driver is a streams based driver. It handles only the system attached keyboard and graphics displays.

#### Sharing Displays with Graphic Subsystem

Certain LFT **ioctl** commands allow graphics subsystems to obtain exclusive use of the displays, a right initially held by the LFT. However, this is done by the Rendering Context Manager (RCM) on behalf of the graphics subsystem. See "Rendering Context Manager" for details of the procedure for becoming a *graphics process*.

#### Subroutine Support

The **lft** special file supports the **open**, **close**, **read**, **write**, and **ioctl** subroutines.

#### ioctl system call

The functions performed by the **ioctl** commands fall into three categories:

- Sharing devices between the **lft** and a graphic subsystem
- Query information about configured displays and keyboard devices

- Compatibility with the common tty ioctl commands

## Sharing devices

| Item                | Description                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IOCINFO             | The IOCINFO ioctl operation is defined for all device drivers that use the ioctl subroutine. The IOCINFO operation returns a <b>devinfo</b> structure, which is defined in the <b>devinfo.h</b> file. |
| LFT_SET_DEFULT_DISP | Sets the default display.                                                                                                                                                                             |
| LFT_ACQ_DISP        | Acquire display for exclusive use.                                                                                                                                                                    |
| LFT_REL_DISP        | Release display.                                                                                                                                                                                      |
| LFT_DIAG_OWNER      | Acquire display for diagnostics.                                                                                                                                                                      |

## Query information about configured displays and keyboard devices

| Item           | Description                   |
|----------------|-------------------------------|
| LFT_QUERY_LFT  | Query common LFT information. |
| LFT_QUERY_DISP | Query display information.    |

## Compatibility with the common tty ioctl commands

TCSAK  
TCGETA  
TCSETAW  
TCSETAF

Low Function Terminal (LFT) Subsystem Overview

## lp Special File

### Purpose

Provides access to the line printer device driver.

### Description

The **lp** driver provides an interface to the port used by a printer.

### Printer Modes

The **lp** driver interprets carriage returns, backspaces, line feeds, tabs, and form feeds in accordance with the modes that are set in the driver (through the **splp** command or configuration). The number of lines per page, columns per line, and the indentation at the beginning of each line can also be selected. The default for these modes can be found using the **lsattr** command. The following modes can be set with the **LPRMODS** ioctl operation:

| Item     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PLOT     | Determines if the data stream is interpreted by the device driver when formatting the text. If the PLOT mode is off, the text is formatted using the current values set with the <b>LPRSET</b> ioctl operation.<br><br>If the PLOT mode is set, no interpretation of the data stream is performed and the bytes are sent to the printer without modification. Setting the PLOT mode causes other formatting modes, such as NOFF and NOFL, to be ignored. The default printer backend, <b>pobe</b> , sends all output in PLOT mode.<br><br>When in PLOT mode, the application must send a final form-feed character. If the last write operation was performed while not in PLOT mode, the final form-feed character will be sent by the device driver. |
| NOFF     | If this mode is on, each form-feed character is replaced with a line-feed character, based on the current line value set with the <b>LPRSET</b> ioctl operation. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NONL     | If this mode is on, each line-feed character is replaced with a carriage return. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NOCL     | If this mode is off, a carriage return is inserted after each line-feed character. If the mode is on, no carriage return is inserted after the line-feed character. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| NOTAB    | If this mode off, 8 position tabs are simulated using spaces. If the NOTAB mode is on, the tab character is replaced with a space. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| NOBS     | If this mode off, backspaces are sent to the printers. If the NOBS mode is on, the backspace is simulated by sending a carriage return followed by spaces to the proper print position. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NOCR     | If this mode on, each carriage return is replaced with a line-feed character. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| CAPS     | If this mode on, lowercase characters are converted to uppercase. This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| WRAP     | If this mode off, the line is truncated at the right margin and any characters received past the right margin are discarded. If the WRAP mode is on, the characters received after the right margin are printed on the next line preceded by ... (ellipsis). This mode is ignored if the PLOT mode is active.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FONTINIT | The FONTINIT mode is initially off. It is turned on by an application when a printer font has been initialized. It can be turned off in the following two cases: <ul style="list-style-type: none"> <li>• An application needs fonts to be reinitialized.</li> <li>• A fatal printer error occurs. In this case, the <b>lp</b> device driver turns the FONTINIT mode off.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                   |
| RPTERR   | If the RPTERR mode is off and an error occurs, the device driver does not return until the error has been cleared or a cancel signal is received. If the RPTERR mode is on, the device driver waits the amount of time specified by a previous <b>LPRSTOV</b> ioctl operation and then returns with an error.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| IGNOREPE | If IGNOREPE mode is on, the device driver allows writes to the device regardless of the state of the PE (paper-end) line on the parallel interface. An application can make use of this mode, for example, to change the paper tray of a printer under software control when detecting that the printer is out of paper.                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Error Handling When the RPTERR Mode Is Off

If the RPTERR mode is off, no error reporting is performed. The device driver waits for the error to be cleared or a cancel signal to be received before returning to the application. RPTERR is the default mode and is intended for existing applications that do not perform error recovery.

If a signal is received by the device driver, the current operation is returned incomplete with an **EINTR** error code.

If printing is canceled and the printer is in PLOT mode, it is the application must send the final form-feed character to eject the partial page. If the printer is not in PLOT mode, the final form-feed character after cancelation will be sent by the device driver.

## Error Handling When the RPTERR Mode Is On

If the RPTERR mode is on, the device driver will wait for the time specified in the **v\_timeout** configuration parameter and then return the uncompleted operation with an error code. This return allows the application to get the printer status and possibly display an error message.

**Note:** When a device driver returns an incomplete operation with an error code (as previously described), the application must resend any data not printed.

## Usage Considerations

### Device-Dependent Subroutines

Most printer operations are implemented using the **open**, **read**, **write**, and **close** subroutines. However, these subroutines provide little or no information to the calling program about the configuration and state of the printer. The **ioctl** subroutine provides a more device-specific interface to the printer device driver.

Most of these subroutines pass data contained in structures. In all cases, a structure of the type indicated should be allocated in the calling routine. A pointer to this structure should then be passed to the device driver.

#### open and close Subroutines

If an adapter for a printer is not installed, an attempt to open fails. If the printer adapter is busy, the **open** subroutine returns an error. However, all child processes created by a parent process that successfully opens the **lp** special file inherit the open printer.

The driver allows multiple **open** subroutines to occur if they all have a *mode* parameter value of read-only. Thus, the **splp** command can perform inquiries when the printer adapter is currently in use. The **lp** driver allows only one process to write to a printer adapter at a time.

The **close** subroutine waits until all output completes before returning to the user.

#### read and write Subroutines

The **read** subroutine is not implemented for the native I/O parallel port.

When printing to a parallel printer that is offline, the **write** subroutine may return one fewer than the actual number of bytes that are buffered and ready to be written when the printer is put back online. This is used as a mechanism to indicate to the calling application that there is a problem with the printer requiring user intervention, possibly allowing the user to put the printer online and continue with printing. In this situation, no error is returned by the **write** subroutine.

#### ioctl Subroutine

The possible ioctl operations and their descriptions are:

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                    |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IOCINFO | Returns a structure defined in the <b>/usr/include/sys/devinfo.h</b> file, which describes the device.                                                                                                                                                                                                                                                                         |
| LPQUERY | Provides access to the printer status. Refer to the <b>/usr/include/sys/lpio.h</b> file for value definitions. The types of errors are the following: <ul style="list-style-type: none"><li>• The printer is out of paper.</li><li>• No select bit: the printer may be turned off or not installed.</li><li>• The printer is busy.</li><li>• The printer is unknown.</li></ul> |

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                     |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LPRGET  | Returns the page length, width and indentation values. These values are used by the device driver when PLOT mode is not set. The default printer backend, <b>piobe</b> , sends all print jobs with PLOT mode set. The LPRGET operation uses the <b>lprio</b> structure, as defined in the <i>/usr/include/sys/lpio.h</i> file.                                                  |
| LPRGETA | Gets the RS232 parameters. These are the values for baud rate, character rate, character size, stop bits and parity. Refer to the <b>LPR232</b> structure and to the <b>termio</b> structure, as defined in the <b>termios.h</b> file.<br><b>Note:</b> This operation is supported for compatibility reasons. The use of the <b>tcgetattr</b> subroutine is recommended.        |
| LPRGTOV | Gets the current time-out value and stores it in the <b>lptimer</b> structure defined in the <i>/usr/include/sys/lpio.h</i> file. The time-out value is measured in seconds.                                                                                                                                                                                                    |
| LPRMODG | Gets the printer modes. These printer modes support the various formatting options and error reporting. This ioctl operation uses the <b>LPRMOD</b> structure, as defined in the <i>/usr/include/sys/lpio.h</i> file.                                                                                                                                                           |
| LPRMODS | Sets the printer modes. These printer modes support the various formatting options and error reporting. This ioctl operation uses the <b>LPRMOD</b> structure, as defined in the <i>/usr/include/sys/lpio.h</i> file.                                                                                                                                                           |
| LPRSET  | Sets the page length, width and indent values. These values are used by the device driver when PLOT mode is not set. The default printer backend, <b>piobe</b> , sends all print jobs with PLOT mode set. The LPRSET operation uses the <b>lprio</b> structure, as defined in the <i>/usr/include/sys/lpio.h</i> file.                                                          |
| LPRSETA | Sets the RS232 parameters. These are the values for baud rate, character rate, character size, stop bits and parity. Refer to the <b>LPR232</b> structure and to the <b>termio</b> structure, as defined in the <b>termios.h</b> header file.<br><b>Note:</b> This operation is supported for compatibility reasons. The use of the <b>tcsetattr</b> subroutine is recommended. |
| LPRSTOV | Sets the time-out value. The <i>arg</i> parameter to this ioctl operation points to a <b>lptimer</b> structure defined in the <i>/usr/include/sys/lpio.h</i> file. The time-out value must be given in seconds.                                                                                                                                                                 |

close subroutine

## Ipfk Special File

### Purpose

Provides access to the lighted program function key (LPFK) array.

### Description

The **lpfk** special file is the application interface to the lighted program function keys. It allows the application to receive operator input from the LPFKs and to illuminate and darken each key in the array.

### Configuration

Standard configuration methods are provided for the **lpfk** special file. The user cannot enter configurable attributes by way of the command line.

### Usage Considerations

#### open

An **open** subroutine call specifying the **lpfk** special file is processed normally except that the *Oflag* and *Mode* parameters are ignored. An open request is rejected if the special file is already opened or if a kernel extension attempts to open the **lpfk** special file. All LPFK inputs are flushed following an open call until an input ring is established.

#### read and write

The **lpfk** special file does not support **read** or **write** subroutine calls. Instead, input data is obtained from the LPFKs through the input ring. The **read** and **write** subroutine calls behave the same as **read** and **write** functions of the **/dev/null** file. See "LFT Input Ring" in *Kernel Extensions and Device Support Programming Concepts* for how to use the input ring.

## ioctl

The **lpfk** special file supports the following **ioctl** operations:

| Item        | Description                           |
|-------------|---------------------------------------|
| IOCINFO     | Returns the <b>devinfo</b> structure. |
| LPFKREGRING | Registers input ring.                 |
| LPFKRFLUSH  | Flushes input ring.                   |
| LPFKLIGHT   | Sets key lights.                      |

## Error Codes

The error codes can be found in the **/usr/include/sys/errno.h** file.

| Item   | Description                                                             |
|--------|-------------------------------------------------------------------------|
| EFAULT | Indicates insufficient authority to access address, or invalid address. |
| EIO    | Indicates I/O error.                                                    |
| ENOMEM | Indicates insufficient memory for required paging operation.            |
| ENOSPC | Indicates insufficient file system or paging space.                     |
| EINVAL | Indicates invalid argument specified.                                   |
| EINTR  | Indicates request interrupted by signal.                                |
| EPERM  | Indicates a permanent error occurred.                                   |
| EBUSY  | Indicates device busy.                                                  |
| ENXIO  | Indicates unsupported device number.                                    |
| ENODEV | Indicates unsupported device, or device type mismatch.                  |

## Ivdd Special File

### Purpose

Provides access to the logical volume device driver.

### Description

The logical volume device driver provides character (raw) access to logical volumes. The Logical Volume Manager associates a major number with each volume group (VG) and a minor number with each logical volume in a volume group.

Logical volume special file names can be assigned by the administrator of the system. However, `/dev/lv1`, `/dev/lv2` and `/dev/rpv1`, `/dev/rpv2` are the names conventionally chosen.

When performing character I/O, each request must start on a logical block boundary of the logical volume. The logical block size of the logical volume is the block size of the physical volume within the volume group. This means that for character I/O to a logical volume device, the offset supplied to the `lseek` subroutine must specify a multiple of logical block size. In addition, the number of bytes to be read or written, supplied to the `read` or `write` subroutine, must be a multiple of the logical block size.

## Usage Considerations

**Note:** Data corruption, loss of data, or loss of system integrity (system crashes) will occur if devices supporting paging, logical volumes, or mounted file systems are accessed using block special files. Block special files are provided for logical volumes and disk devices on the operating system and are solely for system use in managing file systems, paging devices and logical volumes. They should not be used for other purposes. Additional information concerning the use of special files may be obtained in "Understanding I/O Access through Special Files" in *Kernel Extensions and Device Support Programming Concepts*.

### open and close Subroutines

No special considerations.

### Extension Word Specification for the `readx` and `writex` Subroutines

The `ext` parameter for the `readx` and `writex` extended I/O subroutines indicates specific physical or logical operations, or both. The upper 4 bits of the `ext` parameter are reserved for internal LVDD use. The value of the `ext` parameter is defined by logically ORing values from the following list, as defined in the `/usr/include/sys/lvdd.h` file:

| Item                                                                  | Description                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>WRITEV</code>                                                   | Perform physical write verification on this request. This operation can be used only with the <code>writex</code> subroutine.                                                                                                                                                                                                                 |
| <code>RORELOC</code>                                                  | For this request, perform relocation on existing relocated defects only. Newly detected defects should not be relocated.                                                                                                                                                                                                                      |
| <code>MWC_RCV_OP</code>                                               | Mirror-write-consistency recovery operation. This option is used by the recovery software to make consistent all mirrors with writes outstanding at the time of the crash.                                                                                                                                                                    |
| <code>NOMWC</code>                                                    | Inhibit mirror-write-consistency recovery for this request only. This operation can only be used with the <code>writex</code> subroutine.                                                                                                                                                                                                     |
| <code>AVOID_C1</code> , <code>AVOID_C2</code> , <code>AVOID_C3</code> | For this request, avoid the specified mirror. This operation can only be used with the <code>readx</code> subroutine.                                                                                                                                                                                                                         |
| <code>RESYNC_OP</code>                                                | For this request, synchronize the specified logical track group (LTG). This operation can only be used with the <code>readx</code> subroutine and must be the only operation. When synchronizing a striped logical volume, the data returned is not usable by the application because the logical track group is not read on a striped basis. |
| <code>LV_READ_BACKUP</code>                                           | Read only the mirror copy that is designated as the backup mirror copy.                                                                                                                                                                                                                                                                       |
| <code>LV_WRITE_BACKUP</code>                                          | Write only the mirror copy that is designated as the backup mirror copy.                                                                                                                                                                                                                                                                      |
| <code>LV_READ_ONLY_C1</code>                                          | Read only copy one of the data.                                                                                                                                                                                                                                                                                                               |
| <code>LV_READ_ONLY_C2</code>                                          | Read only copy two of the data.                                                                                                                                                                                                                                                                                                               |
| <code>LV_READ_ONLY_C3</code>                                          | Read only copy three of the data.                                                                                                                                                                                                                                                                                                             |
| <code>LV_READ_STALE_C1</code>                                         | Read only copy one of the data even if it is stale.                                                                                                                                                                                                                                                                                           |
| <code>LV_READ_STALE_C2</code>                                         | Read only copy two of the data even if it is stale.                                                                                                                                                                                                                                                                                           |
| <code>LV_READ_STALE_C3</code>                                         | Read only copy three of the data even if it is stale.                                                                                                                                                                                                                                                                                         |

There are some restrictions when using this operation. To synchronize a whole logical partition (LP), a series of **readx** subroutines using the **RESYNC\_OP** operation must be done. The series must start with the first logical track group (LTG) in the partition and proceed sequentially to the last LTG. Any deviation from this will result in an error. The length provided to each **readx** operation must be exactly 128KB (the LTG size).

Normal I/O can be done concurrently anywhere in the logical partition while the **RESYNC\_OP** is in progress. If an error is returned, the series must be restarted from the first LTG. An error is returned only if resynchronization fails for every stale physical partition copy of any logical partition. Therefore, stale physical partitions are still possible at the end of synchronizing an LP.

Normal I/O operations do not need to supply the *ext* parameter and can use the **read** and **write** subroutines.

### IOCINFO ioctl Operation

**IOCINFO** ioctl operation returns the **devinfo** structure, which is defined in the */usr/include/sys/devinfo.h* file. The logical block size of the logical volume is the block size of the physical volume within the volume group. The values returned in this structure are defined as follows for requests to the logical volume device driver:

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>devsubtype</b> | Equal to <b>DS_LV</b> or <b>DS_LVZ</b> . The <b>DS_LVZ</b> <b>devsubtype</b> indicates that the logical volume control block will not occupy the first block of the logical volume, therefore, the space is available for application data. For <b>oldvg</b> format volume groups, the <b>devsubtype</b> of a logical volume is always <b>DS_LV</b> . For <b>bigvg</b> format volume groups, the <b>devsubtype</b> of a logical volume will be <b>DS_LVZ</b> if <b>mklv -T 0</b> was used to create the logical volume. For scalable format volume groups, the <b>devsubtype</b> of a logical volume is always <b>DS_LVZ</b> (regardless of whether or not the <b>mklv -T 0</b> flag was used to create the logical volume). |
| <b>bytpsec</b>    | Bytes per block for the logical volume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>secptrk</b>    | Number of blocks per logical track group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>trkpcyl</b>    | Number of logical track groups per partition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>numblk</b>     | Number of logical blocks in the logical volume                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### XLATE ioctl Operation

The **XLATE** ioctl operation translates a logical address (logical block number and mirror number) to a physical address (physical device and physical block number on that device). The caller supplies the logical block number and mirror number in the **xlate\_arg** structure, which is defined in the */usr/include/sys/lvdd.h* file. The logical block size of the logical volume is the block size of the physical volume within the volume group. This structure contains the following fields:

| Item          | Description                                                                                                   |
|---------------|---------------------------------------------------------------------------------------------------------------|
| <b>lbn</b>    | Logical block number to translate                                                                             |
| <b>mirror</b> | The number of the copy for which to return a <b>pbn</b> (physical block number on disk). Possible values are: |
| 1             | Copy 1 (primary)                                                                                              |
| 2             | Copy 2 (secondary)                                                                                            |
| 3             | Copy 3 (tertiary)                                                                                             |
| <b>p_dev</b>  | Physical <b>dev_t</b> (major/minor number of the disk)                                                        |
| <b>pbn</b>    | Physical block number on disk                                                                                 |

### XLATE64 ioctl Operation

The **XLATE64** ioctl operation functions the same as the **XLATE** operation except that it uses the **xlate\_arg64** structure, in which the logical and physical block numbers and the device (major/minor) number fields are 64-bit wide.

## PBUFCNT ioctl Operation

The PBUFCNT ioctl operation increases the size of the physical buffer header, **pbuf**, pool that is used by LVM for logical-to-physical request translation. The size of this pool is determined by the number of active disks in the system, although the pool is shared for request to all disks.

The PBUFCNT ioctl operation can be issued to any active volume group special file, for example **/dev/VolGrpName**. The parameter passed to this ioctl is a pointer to an unsigned integer that contains the **pbufs-per-disk** value. The valid range is 16 - 128. The default value is 16. This value can only be increased and is reset to the default at IPL. The size of the **pbuf** pool is not reduced when the number of active disks in the system is decreased.

The PBUFCNT ioctl operation returns the following:

| Item         | Description                                                                                                                        |
|--------------|------------------------------------------------------------------------------------------------------------------------------------|
| EINVAL       | Indicates an invalid parameter value. The value is larger than the maximum allowed, or smaller than or equal to the current value. |
| EFAULT       | Indicates that the copy in of the parameter failed.                                                                                |
| LVDD_ERROR   | An error occurred in allocating space for additional buffer headers.                                                               |
| LVDD_SUCCESS | Indicates a successful ioctl operation.                                                                                            |

## LV\_INFO ioctl Operation

The LV\_INFO ioctl operation returns information about the logical volume.

The caller supplies the logical volume special file in the system open call and the information is returned via the **lv\_info** structure, as defined in the **/usr/include/sys/lvdd.h** file. This structure contains the following fields:

| Item                  | Description                                                                                                                                                                                                                 |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>vg_id</b>          | Volume group ID of which the logical volume is a member                                                                                                                                                                     |
| <b>major_num</b>      | Major number of logical volume                                                                                                                                                                                              |
| <b>minor_num</b>      | Minor number of the logical volume                                                                                                                                                                                          |
| <b>max_lps</b>        | Maximum number of logical partitions allowed for this logical volume                                                                                                                                                        |
| <b>current_lps</b>    | Current size of the logical volume in terms of logical partitions                                                                                                                                                           |
| <b>mirror_policy</b>  | Specifies the type of mirroring, if the logical volume is mirrored. Valid values are parallel, sequential, striped, and striped_parallel.                                                                                   |
| <b>permissions</b>    | Specifies whether the logical volume is read only or read-write                                                                                                                                                             |
| <b>bb_relocation</b>  | Specifies whether bad block relocation is activated for the logical volume                                                                                                                                                  |
| <b>write_verify</b>   | Specifies whether the write verify command for writes to the logical volume is enforced                                                                                                                                     |
| <b>num_blocks</b>     | Number of logical blocks that form the logical volume. The logical block size of the logical volume is the block size of the physical volume within the volume group. This value does not include mirrored logical volumes. |
| <b>mwcc</b>           | Specifies which mirrored write consistency check algorithm is set, if it is active.                                                                                                                                         |
|                       | <b>MWCC_NON_ACTIVE</b><br>mwcc disabled for this logical volume                                                                                                                                                             |
|                       | <b>MWCC_ACTIVE_MODE</b><br>ACTIVE mwcc algorithm set for this logical volume                                                                                                                                                |
|                       | <b>MWCC_PASSIVE_MODE</b><br>PASSIVE mwcc algorithm set for this logical volume                                                                                                                                              |
|                       | <b>MWCC_PASSIVE_RECOVERY</b><br>logical mirrors undergoing PASSIVE mwcc recovery after system interruption                                                                                                                  |
| <b>mirr_able</b>      | Specifies whether the logical volume is capable of being mirrored                                                                                                                                                           |
| <b>num_mirrors</b>    | Number of mirror copies for this logical volume                                                                                                                                                                             |
| <b>striping_width</b> | Number of drives across which this logical volume is striped                                                                                                                                                                |
| <b>stripe_exp</b>     | Stripe block exponent value                                                                                                                                                                                                 |

| Item                       | Description                                                                   |
|----------------------------|-------------------------------------------------------------------------------|
| <code>backup_mirror</code> | Backup mirror mask will be zero indicating there is not a backup copy active. |
| <code>AVOID_C1</code>      | For the first copy                                                            |
| <code>AVOID_C2</code>      | For the second copy                                                           |
| <code>AVOID_C3</code>      | For the third copy.                                                           |

The `LV_INFO` ioctl operation returns the following:

| Item                | Description                                      |
|---------------------|--------------------------------------------------|
| <code>EFAULT</code> | Indicates that the copy of the parameter failed. |

### LVM ioctl Operations Used to Modify Single Logical Volumes

| Item                        | Description                                                                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>LV_QRYBKPCOPY</code>  | Query for designated backup mirror copy.                                                                                                                   |
| <code>LV_SETBKPCOPY</code>  | Designate backup mirror copy.                                                                                                                              |
| <code>LV_FSETBKPCOPY</code> | Force new designation for backup mirror copy. Used when there are stale partitions on either the active mirror or backup mirror.                           |
| <code>SET_SYNC_ON_RD</code> | Causes the logical volume to go into MWCC_PASSIVE_RECOVERY mode. All reads from one mirror copy will cause non-read mirror copies to undergo a sync write. |
| <code>CLR_SYNC_ON_RD</code> | Clears the MWCC_PASSIVE_RECOVERY mode of the logical volume, if it exists. This clear should not be exercised if mirror consistency is not guaranteed.     |

### `LV_INFO64` ioctl Operation

The `LV_INFO64` ioctl operation functions the same as the `LV_INFO` operation except that it uses the `lv_info64` structure, in which the `major_num` and `minor_num` fields are 32-bit wide each and the `num_blocks` field is 64-bit wide.

### `LVM_CFG_ASSIST` ioctl Operation

The `LVM_CFG_ASSIST` ioctl operation returns the performance statistics of a logical volume. It returns the `cfg_assist` structure, which is defined in the `/usr/include/sys/lvdd.h` file. This structure contains the following fields:

| Item                         | Description                                                                                                                                                                                                        |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>throughput</code>      | Average throughput of the disks in the logical volume in KB/sec. For supported storage devices, throughput is obtained from the device; otherwise, runtime throughput of the logical volume is returned.           |
| <code>latency</code>         | Average latency of the disks in the logical volume in milliseconds. For supported storage devices, throughput is obtained from the device; otherwise, runtime latency of the logical volume is returned.           |
| <code>flags</code>           | Flags to be used. For a list of valid flags, see the <code>/usr/include/sys/lvdd.h</code> file.                                                                                                                    |
| <code>vg_max_transfer</code> | The maximum transfer size of the volume group (VG), in KB. The <code>vg_max_transfer</code> field value is the maximum amount of data that can be transferred in one I/O request to the disks of the volume group. |
| <code>write_atomicity</code> | Write atomicity in Bytes. The <code>write_atomicity</code> field value is the largest number of bytes that are not broken up when they are written on aligned boundaries.                                          |

The `LVM_CFG_ASSIST` ioctl operation returns the following parameters only for supported storage devices; otherwise, it returns a null value.

| Item                        | Description                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| atomicWriteAlignment        | Required alignment for write atomicity in KB.                                                                                             |
| ideal_sequential_read_size  | Ideal, sequential, read size of the disks under the file system in KB.                                                                    |
| ideal_sequential_write_size | Ideal, sequential, write size of the disks under the file system in KB.                                                                   |
| ideal_random_read_size      | Ideal, random, read size of the disks under the file system in KB.                                                                        |
| ideal_random_write_size     | Ideal, random, write size of the disks under the file system in KB.                                                                       |
| stripsize                   | Strip size of the disks under the file system in KB. This is the amount of data that is contiguous on a single spindle in the raid array. |
| stripesize                  | Stripesize is in KB. (Stripesize = stripsize x num spindles in raid array – parity.)                                                      |
| parallelism                 | Number of spindles that comprise the RAID device that can be concurrently read from, and written to, in parallel.                         |

## Return Values

When you complete this operation, a value of 0 is returned. If the operation fails, a value of -1 is returned and the **errno** global variable is set to one of the following values:

| Item   | Description                                                                                                                                                                     |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EFAULT | Indicates that the copy of the parameter failed.                                                                                                                                |
| ENOMEM | Indicates that the allocation of the memory failed.                                                                                                                             |
| EAGAIN | Indicates that the runtime statistics are unavailable for any of the physical volumes in the logical volume.<br>Try again after more I/O has been issued to the logical volume. |

## FORCEOFF\_VG ioctl Operation

You can force a volume group offline by the **FORCEOFF\_VG** ioctl operation. You can issue this operation to any active volume group special file, for example the **/dev/VolGrpName** file. The parameter passed to this ioctl is a pointer to an integer that contains the value **FORCE\_VG\_OFF** as defined in the **/usr/include/sys/lvdd.h** file.

When you force the volume group offline, subsequent logical volume opens, and I/O requests and changes for volume group configuration fail. You must vary off the volume group and vary it on again to clear the forced offline condition.

If this operation is completed, a value of 0 is returned. Otherwise, a value of -1 is returned and the **errno** global variable is set to one of the following values:

| Item   | Description                                        |
|--------|----------------------------------------------------|
| EFAULT | Indicates that the copy-in of the parameter fails. |
| EINVAL | Indicates the parameter value is not valid.        |

## Error Codes

In addition to the possible general errors returned by the **ioctl** subroutine, the following errors can also be returned from specific ioctl operation types.

| Item  | Description                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ENXIO | The logical volume does not exist. (This error type is relevant to the <b>IOCINFO</b> , <b>XLATE</b> ioctl, and <b>XLATE64</b> operations.)                                            |
| ENXIO | The logical block number is larger than the logical volume size. (This error type is relevant only to the <b>XLATE</b> ioctl and <b>XLATE64</b> ioctl operations.)                     |
| ENXIO | The copy (mirror) number is less than 1 or greater than the number of actual copies. (This error type is relevant only to the <b>XLATE</b> ioctl and <b>XLATE64</b> ioctl operations.) |
| ENXIO | No physical partition has been allocated to this copy (mirror). (This error type is relevant only to the <b>XLATE</b> ioctl and <b>XLATE64</b> ioctl operations.)                      |

## mem or kmem Special File

### Purpose

Provides privileged virtual memory read and write access.

### Description

**Note:** When incorrect access to virtual memory is made through these files, process termination, a system crash, or loss of system data integrity can result.

The **/dev/mem** and **/dev/kmem** character special files provide access to a pseudo device driver that allows read and write access to system memory or I/O address space. Typically, these special files are used by operating system utilities and commands (such as **sar**, **iostat**, and **vmstat**) to obtain status and statistical information about the system.

**Note:** Programs accessing these special files must have appropriate privilege. Commercial application programs should avoid using the **/dev/mem** and **/dev/kmem** files, since the virtual memory image is quite specific to the operating system level and machine platform. Use of these special files thus seriously affects the portability of the application program to other systems.

### Usage Considerations

#### kmem Special File Access

The **kmem** special file provides access to the virtual memory address space for the current process, as it is seen by the kernel. The seek offset, set by the **Iseek** subroutine, is used to specify the virtual address targeted for the read or write. The **kmem** pseudo-device driver only supports the **open**, **close**, **read**, **readx**, **writex**, and **write** subroutines.

The **knlist** system subroutine is typically used to obtain the addresses of kernel symbols to read or write through access provided by the **kmem** special file.

Before issuing a read or write operation, the **Iseek** subroutine must be used to designate the relevant starting address in virtual memory. If this address is within the first two gigabytes of address space, then the **read** or **write** subroutine calls can be used. However, if the upper two gigabytes of address space are to be accessed, the **readx** and **writex** form of the subroutine calls must be used. In this case, the **ext** (extension) parameter must be set to a value of True. This causes the **Iseek** offset to be interpreted relative to the upper 2 gigabytes of address space.

**Note:** The process address space is defined as shown in the Implementation of mem Special File Access section. This address space layout can vary on other machine platforms and versions of the operating system.

### **mem Special File Access**

**Note:** Use of this special file by application programs should be strictly avoided, as it is provided for diagnostic and problem determination procedures only.

The **mem** special file access is specific to the system on which the operating system is running.

Please refer to the Implementation of mem Special File Access section for details on the function provided by this special file.

### **Process Address Space Regions for the /dev/kmem Special File**

The "Process Address Space Map" illustrates the layout of process address space regions as accessed through the **/dev/kmem** special file on this system.

| <b>Item</b>                                                                                    | <b>Description</b>                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### **Implementation of mem Special File Access**

The **mem** special file has traditionally provided direct access to physical memory. This capability and its interface requirements are machine-specific. However, for this operating system this function is indirectly provided by using the *ext* (extension) parameter on the **readx** and **writex** subroutine calls. When a **readx** or **writex** subroutine call associated with the **/dev/mem** special file is issued, the *ext* parameter must contain a valid segment register value as defined in the *POWERstation and POWERserver Hardware*

*Technical Reference - General Information* documentation for the platform types(s) on which the program will be run. This allows the program to access all physical memory mapped by the page table as well as the platform-specific I/O (T=1) segments.

The seek offset set by the **Iseek** subroutine call is used to specify the address offset within the segment described by the *ext* parameter. The upper four bits of the offset are not used. The pseudo-device driver only supports the **open**, **close**, **read**, **readx**, **write**, and **writex** subroutine calls. The **Iseek** subroutine call must also be used before the **readx** or **writex** subroutine calls are issued, in order to specify the address offset.

If a **read** or **write** subroutine call is used with this special file, the access to memory is identical to that provided by the **/dev/kmem** special file.

The **mem** special file is part of Base Operating System (BOS) Runtime.

## Files

| Item             | Description                                               |
|------------------|-----------------------------------------------------------|
| <b>/dev/mem</b>  | Provides privileged virtual memory read and write access. |
| <b>/dev/kmem</b> | Provides privileged virtual memory read and write access. |

## mouse Special File

### Purpose

Provides access to the natively attached mouse.

### Description

The **mouse** special file serves as an interface between the application interface and the system mouse. This special file provides the application with the ability to receive input from the mouse and allows the application to change mouse configuration parameters, such as mouse sampling rates and resolution.

### Configuration

Standard configuration methods work with the mouse special file. No user configurable attribute commands exist for this special file. Applications that open the special file can modify device attribute dynamically using the appropriate ioctl interface; however, modifications are not saved in the configuration database.

### Usage Considerations

The **open** subroutine call specifying the **mouse** special file is processed normally except that the *Oflag* and *Mode* parameters are ignored. The **open** request is rejected when the special file is already opened or when a kernel extension attempts to open the special file. All mouse inputs are flushed following an **open** subroutine call until an input ring is established. The mouse device is reset to the default configuration when an open request is made.

The **mouse** special file does not support the **read** or **write** subroutine calls. Instead, input data is obtained from the mouse via the input ring. The **read** and **write** subroutine calls behave the same as **read** or **write** to the **/dev/null** file.

The **mouse** special file supports the following functions with ioctl:

| Item        | Description                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------|
| IOCINFO     | Returns a <b>devinfo</b> structure.                                                                                            |
| MQUERYID    | Returns the query mouse device identifier.                                                                                     |
| MREGRING    | Specifies the address of the input ring and the value to be used as the source identifier when enqueueing reports on the ring. |
| MRFLUSH     | Flushes the input ring.                                                                                                        |
| MTHRESHOLD  | Sets the mouse reporting threshold.                                                                                            |
| MRESOLUTION | Sets the mouse resolution.                                                                                                     |
| MSCALE      | Sets the mouse scale factor.                                                                                                   |
| MSAMPLERATE | Sets the mouse sample rate.                                                                                                    |

## Error Codes

The following error codes can be found in the **/usr/include/sys/errno.h** file:

| Item   | Description                                                               |
|--------|---------------------------------------------------------------------------|
| EFAULT | Indicates insufficient authority to access an address or invalid address. |
| EIO    | Indicates an I/O error.                                                   |
| ENOMEM | Indicates insufficient memory for required paging operation.              |
| ENOSPC | Indicates insufficient file system or paging space.                       |
| EINVAL | Indicates invalid argument specified.                                     |
| EINTR  | Indicates that the request has been interrupted by a signal.              |
| EPERM  | Specifies a permanent error occurred.                                     |
| EBUSY  | Indicates a device is busy.                                               |
| ENXIO  | Indicates an unsupported device number.                                   |
| ENODEV | Indicates an unsupported device or device type mismatch.                  |
| EACCES | Indicates that an open is not allowed.                                    |

## Files

## mpcn Special File

### Purpose

Provides access to the HDLC network device driver by way of the SDLC COMIO device driver emulator.

### Description

The **/dev/mpcn** character special file provides access to the HDLC network device driver via the SDLC COMIO device driver emulator in order to provide access to a synchronous network. The SDLC COMIO emulator device handler supports multiple HDLC network devices.

## Usage Considerations

When accessing the SDLC COMIO emulator device handler, consider the following information.

### Driver Initialization and Termination

The device handler can be loaded and unloaded. The handler supports the configuration calls to initialize and terminate itself.

### Special File Support

The SDLC COMIO emulator device handler uses the **t\_start\_dev** and **t\_chg\_parms** structures defined in the **/usr/include/sys/mpqp.h** file to preserve compatibility with the existing GDLC, MPQP API, and SNA Services interface. However, only a subset of the **#define** values are supported for the following **t\_start\_dev** structure fields:

| Item       | Description                                                                                                                                                                                                                                                             |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| phys_link  | Indicates the physical link protocol. Only one type of physical link is valid at a time. The SDLC COMIO emulator device handler supports PL_232D (EIA-232D), PL_422A (EIA-422A/v.36), PL_V35 (V.35), PL_X21 (X.21 leased only), and PL_V25 (V.25bis EIA-422A autodial). |
| data_proto | Identifies the data protocol. The SDLC COMIO emulator device handler supports only the SDLC DATA_PRO_SDLC_HDX (half duplex) and the DATA_PRO_SDLC_FDX (full duplex) values.                                                                                             |
| baud_rate  | Specifies the baud rate for transmit and receive clocks. The SDLC COMIO emulator device handler supports only external clocking where the DCE supplies the clock, and this field should be set to zero.                                                                 |

### Subroutine Support

The SDLC COMIO emulator device handler supports the **open**, **close**, **read**, **write**, and **ioctl** subroutines in the following manner:

#### open and close Subroutines

The device handler supports the **/dev/mpcn** special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). No special considerations exist for closing the special file.

#### read Subroutine

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine call. For this call, the device handler copies the user data in to the buffer specified by the caller.

#### write Subroutine

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine call. For this call, the device handler copies the user data into a buffer and transmits the data on the wide area network using the HDLC network device driver.

#### ioctl Subroutine

The **ioctl** subroutine supports the following flags:

| Item         | Description                                                                                                                                                         |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CIO_START    | Starts a session and registers a network ID.                                                                                                                        |
| CIO_HALT     | Halts a session and removes a network ID.                                                                                                                           |
| CIO_QUERY    | Returns the current reliability, availability, and serviceability (RAS) counter values. These values are defined in the <code>/usr/include/sys/comio.h</code> file. |
| MP_CHG_PARMS | Permits the data link control (DLC) to change certain profile parameters after the SDLC COMIO device driver emulator is started.                                    |

## Error Codes

The following error codes can be returned when gaining access to the device handler through the `/dev/mpcn` special file:

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ECHRNG    | Indicates that the channel number is out of range.                                                                                                                                                                                                                                                                                                                                                                                    |
| EAGAIN    | Indicates that the device handler cannot transmit data because of a lack of system resources, or, because an error returned from the HDLC network device driver's transmit routine.                                                                                                                                                                                                                                                   |
| EBUSY     | Indicates that the device handler is already in use (opened/started) by another user.                                                                                                                                                                                                                                                                                                                                                 |
| EIO       | Indicates that the handler cannot queue the request to the adapter.                                                                                                                                                                                                                                                                                                                                                                   |
| EFAULT    | Indicates that the cross-memory copy service failed.                                                                                                                                                                                                                                                                                                                                                                                  |
| EINTR     | Indicates that a signal has interrupted the sleep.                                                                                                                                                                                                                                                                                                                                                                                    |
| EINVAL    | Indicates one of the following: <ul style="list-style-type: none"> <li>The port is not set up properly.</li> <li>The handler cannot set up structures for <code>write</code>.</li> <li>The port is not valid.</li> <li>A kernel process called a <code>select</code> operation.</li> <li>The specified physical-link parameter is not valid for that port.</li> <li>A kernel process called a <code>read</code> operation.</li> </ul> |
| ENOMEM    | Indicates one of the following: <ul style="list-style-type: none"> <li>No mbuf or mbuf clusters are available.</li> <li>The total data length is more than one page.</li> <li>There is no memory for internal structures.</li> </ul>                                                                                                                                                                                                  |
| ENOMSG    | Indicates that the status-queue pointer is null, and there are no entries.                                                                                                                                                                                                                                                                                                                                                            |
| ENOTREADY | Indicates that the port state in the define device structure (DDS) is not in Data Transfer mode or that the implicit halt of port failed.                                                                                                                                                                                                                                                                                             |
| ENXIO     | Indicates one of the following: <ul style="list-style-type: none"> <li>The port was not started successfully.</li> <li>The channel number is illegal.</li> <li>The driver control block pointer is null or does not exist.</li> </ul>                                                                                                                                                                                                 |

This file functions with the SDLC COMIO emulator device handler over the HDLC network device driver. It emulates the SDLC API (full and half duplex) of the Multiprotocol Quad Port (MPQP) device handler.

MPQP Device Handler Interface Overview

## mpqi Special File

### Purpose

Provides access to the Multiport Model 2 Adapter (MM2) device driver via SNA Services, GDLC, or user-written applications compatible with current MPQP Applications Programming Interface (API).

## Description

The Multiport Model 2 device driver provides access to the **mpqi** special file through SNA Services, Generic Data Link Control, or through user-written applications.

### Usage Considerations

When accessing the Multiport Model 2 device driver via these methods, consider the following information:

#### Driver Initialization and Termination

The device driver can be loaded and unloaded in the kernel in the same way as other communications device drivers. The device driver supports the configuration calls to initialize and terminate itself. Therefore, you must ensure that the device driver is initialized before using it. A listing of the device driver, either via SMIT or by using the **lsdev** command, should indicate the device driver state as *Available*.

#### Special File Support

The Multiport Model 2 device driver is a character I/O device and provides a special file entry in the **/dev** directory for file system access. The Multiport Model 2 device driver uses the **t\_start\_dev** and **t\_chg\_parms** structures defined in the **/usr/include/sys/mpqp.h** file to preserve compatibility with the existing GDLC, MPQP API and SNA Services interface. However, only a subset of the **#define** values is supported for the following **t\_start\_dev** structure fields:

| Item              | Description                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>data_proto</b> | Identifies the data protocol. The Multiport Model 2 device driver supports the SDLC DATA_PRO_SDLC_HDX value (indicating half duplex only) and the bisync DATA_PRO_BSC value.                                                                                                                                                                                 |
| <b>baud_rate</b>  | Specifies the baud rate for transmit and receive clock. The Multiport Model 2 device driver only supports external clocking where the modem supplies the clock, and this field should be set to zero. However, when using SNA Services, this field is ignored when external clocking is specified in the physical link profile and does not need to be zero. |

MPQP Device Handler Interface Overview

Data Link Control

## mpqn Special File

### Purpose

Provides access to multiprotocol adapters by way of the Multiprotocol Quad Port (MPQP) device handler.

### Description

The **/dev/mpqn** character special file provides access to the MPQP device handler for the purpose of providing access to a synchronous network. The MPQP device handler supports multiple adapters.

### Usage Considerations

When accessing the MPQP device handler, the following should be taken into account:

#### Driver initialization and termination

The device handler may be loaded and unloaded. The handler supports the configuration calls to initialize and terminate itself.

## Special file support

Calls other than the **open** and **close** subroutine calls are discussed in relation to the mode in which the device handler is operating.

### Subroutine Support

The MPQP device handler supports the **open**, **close**, **read**, **write**, and **ioctl** subroutines in the following manner:

- The **open** and **close** subroutines

The device handler supports the */dev/mpqn* special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). There are no particular considerations for closing the special file. Which special file name is used in an **open** call depends on how the device is to be opened. Types of special file names are:

| Item               | Description                                                         |
|--------------------|---------------------------------------------------------------------|
| <i>/dev/mpqn</i>   | Starts the device handler for the selected port.                    |
| <i>/dev/mpqn/D</i> | Starts the device handler in Diagnostic mode for the selected port. |

- The **read** subroutine

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine call. For this call, the device handler copies the data into the buffer specified by the caller.

- The **write** subroutine

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine call. For this call, the device handler copies the user data into a buffer and transmits the data on the LAN.

- The **ioctl** subroutine

| Item                | Description                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------|
| <b>CIO_START</b>    | Starts a session and registers a network ID.                                                                     |
| <b>CIO_HALT</b>     | Halts a session and removes a network ID.                                                                        |
| <b>CIO_QUERY</b>    | Returns the current RAS counter values. These values are defined in the <i>/usr/include/sys/comio.h</i> file.    |
| <b>CIO_GET_STAT</b> | Returns the current adapter and device handler status.                                                           |
| <b>MP_START_AR</b>  | Puts the MPQP port into Autoresponse mode.                                                                       |
| <b>MP_STOP_AR</b>   | Permits the MPQP port to exit Autoresponse mode.                                                                 |
| <b>MP_CHG_PARMs</b> | Permits the data link control (DLC) to change certain profile parameters after the MPQP device has been started. |
| <b>MP_SET_DELAY</b> | Sets the value of <b>NDELAY</b> .                                                                                |

## Error Codes

The following error codes may be returned when accessing the device handler through the */dev/mpqn* special file:

| Item          | Description                                                                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ECHRNG</b> | Indicates that the channel number is out of range.                                                                                                                                                                                                                                                                                     |
| <b>EAGAIN</b> | Indicates that the maximum number of direct memory accesses (DMAs) was reached, so that the handler cannot get memory for internal control structures.                                                                                                                                                                                 |
| <b>EBUSY</b>  | Indicates one of the following: <ul style="list-style-type: none"><li>• The port is not in correct state.</li><li>• The port should be configured, but is not opened or started.</li><li>• The port state is not opened for start of an ioctl operation.</li><li>• The port is not started or is not in data-transfer state.</li></ul> |
| <b>EIO</b>    | Indicates that the handler could not queue the request to the adapter.                                                                                                                                                                                                                                                                 |
| <b>EFAULT</b> | Indicates that the cross-memory copy service failed.                                                                                                                                                                                                                                                                                   |
| <b>EINTR</b>  | Indicates that the sleep was interrupted by a signal.                                                                                                                                                                                                                                                                                  |

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EINVAL    | Indicates one of the following: <ul style="list-style-type: none"> <li>• The port not set up properly.</li> <li>• The handler could not set up structures for write.</li> <li>• The port is not valid.</li> <li>• A select operation was called by a kernel process.</li> <li>• The specified physical-link parameter is not valid for that port.</li> <li>• The read was called by a kernel process.</li> </ul>                                                                                                                                 |
| ENOMEM    | Indicates one of the following: <ul style="list-style-type: none"> <li>• No mbuf or mbuf clusters are available.</li> <li>• The total data length is more than a page.</li> <li>• There is no memory for internal structures.</li> </ul>                                                                                                                                                                                                                                                                                                         |
| ENOMSG    | Indicates that the status-queue pointer is null, and there are no entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| ENOTREADY | Indicates that the port state in define device structure (DDS) is not in Data Transfer mode or that the implicit halt of port failed.                                                                                                                                                                                                                                                                                                                                                                                                            |
| ENXIO     | Indicates one of the following: <ul style="list-style-type: none"> <li>• The port has not been started successfully.</li> <li>• An invalid adapter number was specified.</li> <li>• The channel number is illegal.</li> <li>• The adapter is already open in Diagnostic mode.</li> <li>• The adapter control block (ACB) pointer is null or does not exist.</li> <li>• The registration of the interrupt handler failed.</li> <li>• The port does not exist or is not in proper state.</li> <li>• The adapter number is out of range.</li> </ul> |

The communication device handler topic defines specific errors returned on each subroutine call.

MPQP Device Handler Interface Overview

## mstor Special File

### Purpose

Provides access to the virtual removable disk device.

### Description

The **mstor** special file provides block and character (raw) access to the virtual removable disk devices, which are backed by the Universal Serial Bus (USB) mass storage devices (such as RDX, flash drives, and storage devices) on the Virtual I/O Server (VIOS). The capability of the AIX operating system to read from and write to the virtual removable disk drives is validated against the IBM RDX and a sample of industry standard original equipment manufacturer (OEM) USB flash drives is used as backing store on VIOS.

**Note:** The AIX Small Computer System Interface (SCSI) disk driver supports virtual removable disks on the AIX Version 6.1 with Technology Level 6100-09, and later, and on the AIX Version 7.1 with Technology Level 7100-03, and later.

The backing USB mass storage devices can be exported to only one client at a time. If the user wants to export the backing device to another client, the virtual removable disk device must be removed from the old client by using the **rmdev** command and then, the backing device must be remapped to the new client on the VIOS.

The virtual removable disk drivers are configured by using the logical names, such as mstor0 and mstor1. The driver presents both **raw** and **blocks** special files. For example, the raw special file for the **mstor0** file is /dev/rmstor0 file, and the block special file is /dev/mstor0. To install raw I/O on a virtual removable disk, all data transfers in multiples of block length (512 bytes) the virtual removable disk device is required. Also, all the **lseek** subroutines made to the virtual removable disk device driver must set the file offset pointer to a value that is a multiple of the specified logical block size.

A virtual removable disk device cannot be used with the AIX Logical Volume Manager (LVM) or the AIX Journaled File System (JFS) or JFS2 file systems. A virtual removable disk device can be used with the User-defined file system (UDFS) file system, with backup commands, such as **tar** and the **savevg** commands, and with media access commands, such as the **dd** command. The user can also create a **mksysb** image on the device and can start and install from the device. It can be used as a memory dump device on the AIX operating system.

The virtual removable disk device is dependent on the device or media that is connected and available on the VIOS. When the backing USB disk device is disconnected from the VIOS while the device is still in use on the AIX client, the device becomes unavailable on the client. On reconnecting the USB device to VIOS, the device must be remapped by removing the older mapping and then creating a new mapping, running the **cfgmgr** command on the AIX client to make the device available again on client. This task can be accomplished by running the following commands:

### On Virtual I/O Server

1. To get the current mapping, run the following command:

```
lsmap -all
```

2. To remove the current mapping, run the following command:

```
rmvdev -vtd VTD of the device from lsmap
```

3. To create the new mapping, run the following command:

```
mkvdev -vdev usb device -vadapter virtual adapter name
```

### On an AIX client

```
cfgmgr
```

The removable disk devices defines a *prevent\_eject* attribute, which has a default value of **yes** and can be changed by using the System Management Interface Tool (SMIT) interface or the **chdev** command. If a user sets the value of the *prevent\_eject* attribute as **yes**, it causes a Media Eject Prevent and Media Eject Allow action while opening and closing of the device. This operation is only applicable if the backing device has ejectable media and this operation is not supported for flash drives.

If the backing device has ejectable media and the *prevent\_eject* attribute is set to **no**, and the media is ejected from the drive for an exported UDFS file system, the files on the disk cartridge cannot be accessed. To access these files again, the file systems that are mounted from the virtual removable disk drive must be unmounted. The processes that have files in an open state on these file systems must be exited. The processes that have current directories on these file systems must be moved. If these actions fail, perform a forced unmount operation.

## Device-Dependent Subroutines

Most virtual disk device operations are implemented by using the **open**, **read**, and **close** subroutines. However, for some purposes, the **openx** (extended) subroutine must be used..

| Subroutines             | Description                                                                                                                                                                                                                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ioctl Subroutine</b> | The virtual removable disk device uses SCSI disk device driver for its operation. It supports <b>ioctls</b> operations which are supported by the SCSI disk driver, such as the IOCINFO, DKIOLCMD, DK_PASSTHRU, DKPMR, DKAMR, and DKEJECT operations.                                                                                     |
| <b>openx Subroutine</b> | The <b>openx</b> subroutine is supported to provide more functions to the <b>open</b> sequence. The <b>openx</b> subroutine requires appropriate authority to start. If you attempt to run this subroutine without the access right might results in a return value of -1, with the <i>errno</i> global variable is set to <i>Eperm</i> . |

## Error Codes

In addition to the error codes listed for the **ioctl**, **open**, **read**, and **write** subroutines. The following error codes are also supported:

| Error code       | Description                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>EACCES</b>    | A subroutine other than <b>ioctl</b> or <b>close</b> was attempted while in diagnostic mode.                              |
| <b>EACCES</b>    | A normal read call was attempted while in diagnostic mode.                                                                |
| <b>EFAULT</b>    | An incorrect user address.                                                                                                |
| <b>EBUSY</b>     | The target device is reserved by another initiator.                                                                       |
| <b>EINVAL</b>    | A <i>nbyte</i> parameter of a <b>read</b> subroutine is not an even multiple of the block size.                           |
| <b>EINVAL</b>    | An attempt was made to configure a device that is still open.                                                             |
| <b>EINVAL</b>    | An incorrect configuration command is entered.                                                                            |
| <b>EMFILE</b>    | An open call is attempted for a SCSI adapter that already has the maximum permissible number of open devices.             |
| <b>ENOTREADY</b> | There is no cartridge in the drive that is attached to VIOS.                                                              |
| <b>ENODEV</b>    | An attempt was made to access a device that is not defined.                                                               |
| <b>ENODEV</b>    | An attempt was made to close a device that is not defined.                                                                |
| <b>EMEDIA</b>    | The media was changed.                                                                                                    |
| <b>EIO</b>       | A hardware error, an aborted command, invalid request.                                                                    |
| <b>EIO</b>       | An attempt is made to read beyond the end of media.                                                                       |
| <b>EPERM</b>     | The subroutine requires appropriate authority.                                                                            |
| <b>ESTALE</b>    | The media was ejected (without first being closed by the user) and then either reinserted or replaced with a second disk. |
| <b>ETIMEDOUT</b> | An I/O operation exceeded the specified timer value.                                                                      |

## null Special File

### Purpose

Provides access to the null device, typically for writing to the bit bucket.

### Description

The **/dev/null** special file provides character access to the null device driver. This device driver is normally accessed to write data to the bit bucket (when the data is to be discarded).

### Usage Considerations

When using subroutines with the null device file, consider the following items:

| Item                              | Description                                                                                                                                                                                                     |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>open and close subroutines</b> | The null device can be opened by using the <b>open</b> subroutine with the <b>/dev/null</b> special file name. The <b>close</b> subroutine should be used when access to the null device is no longer required. |
| <b>read and write subroutines</b> | Data written to this file is discarded. Reading from this file always returns 0 bytes.                                                                                                                          |
| <b>ioctl subroutine</b>           | There are no <b>ioctl</b> operations available for use with the <b>null</b> special file. Any ioctl operation issued returns with the <b>ENODEV</b> error type.                                                 |

## nvram Special File

### Purpose

Provides access to platform-specific nonvolatile RAM used for system boot, configuration, and fatal error information. This access is achieved through the machine I/O device driver.

### Description

The **/dev/nvram** character special file provides access to the machine device driver for accessing or modifying machine-specific nonvolatile RAM. The appropriate privilege is required to open the **nvram** special file. The **nvram** special file is used by machine-specific configuration programs to store or retrieve configuration and boot information using the nonvolatile RAM or ROM provided on the machine. The **nvram** special file supports open, close, read, and ioctl operations.

**Note:** Application programs should not access the nonvolatile RAM. Since nonvolatile RAM is platform-specific, any reliance on its presence and implementation places portability constraints upon the using application. In addition, accessing the nonvolatile RAM may cause loss of system startup and configuration information. Such a loss could require system administrative or maintenance task work to rebuild or recover.

For additional information concerning the use of this special file to access machine-specific nonvolatile RAM, see the "Machine Device Driver" in *Technical Reference: Kernel and Subsystems, Volume 1*.

### Usage Considerations

When using subroutines with the **nvram** special file, consider the following items.

#### open and close Subroutines

The machine device driver supports the **nvram** special file as a multiplexed character special file.

A special channel name of **base** can be used to read the base customize information stored as part of the boot record. The **nvram** special file must be opened with a channel name of **base**, as follows:

`/dev/nvram/base`

The special file **/dev/nvram/base** can only be opened once. When it is closed for the first time after a boot, the buffer containing the base customize information is free. Subsequent opens return a **ENOENT** error code.

#### read, write, and lseek Subroutines

The **read** subroutine is supported after a successful open of the **nvram** special file with a channel name of **base**. The **read** operation starts transferring data at the location associated with the base customization information and with an offset specified by the offset value associated with the file pointer being used on the subroutine.

On a **read** subroutine, if the end of the data area is reached before the transfer count is reached, the number of bytes read before the end of the data area was reached is returned. If the read starts after the end of the data area, an error of **ENXIO** is returned by the driver.

The **lseek** subroutine can be used to change the starting read offset within the data area associated with the base customization information. The **write** subroutine is not supported on this channel and results in an error return of **ENODEV**.

### ioctl Subroutine

**ioctl** commands can be issued to the machine device driver after the **/dev/nvram** special file has been successfully opened. The **IOCINFO** parameter returns machine device driver information in the caller's **devinfo** structure, as pointed to by the *arg* parameter to the **ioctl** subroutine. This structure is defined in the **/usr/include/sys/devinfo.h** file. The device type for this device driver is **DD\_PSEU**.

### Error Codes

The following error conditions can be returned when accessing the machine device driver using the **nvram** special file name:

| Item          | Description                                                                                                     |
|---------------|-----------------------------------------------------------------------------------------------------------------|
| <b>EFAULT</b> | A buffer specified by the caller was invalid on a <b>read</b> , <b>write</b> , or <b>ioctl</b> subroutine call. |
| <b>ENXIO</b>  | A read operation was attempted past the end of the data area specified by the channel.                          |
| <b>ENODEV</b> | A write operation was attempted.                                                                                |
| <b>ENOMEM</b> | A request was made with a user-supplied buffer that is too small for the requested data.                        |

## Security

Programs attempting to open the **nvram** special file require the appropriate privilege.

## random and urandom Devices

### Purpose

Source of secure random output.

### Description

The **/dev/random** and **/dev/urandom** character devices provide cryptographically secure random output generated from interrupt timings or input written to the devices.

The **/dev/random** device is intended to provide high quality, cryptographically secure random output and will only return output for which sufficient (an equal or greater amount) random input is available to generate the output. If insufficient random input is available, reads from the **/dev/random** device will block until the request can be fulfilled unless the O\_NONBLOCK flag was specified when the device was opened, in which case as much high quality output as could be generated is returned with the error code EAGAIN.

The **/dev/urandom** device provides a reliable source of random output, however the output will not be generated from an equal amount of random input if insufficient input is available. Reads from the **/dev/urandom** device always return the quantity of output requested without blocking. If insufficient random input is available, alternate input will be processed by the random number generator to provide cryptographically secure output, the strength of which will reflect the strength of the algorithms used by the random number generator. Output generated without random input is theoretically less secure than output generated from random input, so **/dev/random** should be used for applications for which a high level of confidence in the security of the output is required.

Data written to either device is added to the pool of stored random input and may be used for generating output. Writes behave identically for both devices and will not block.

## Implementation Specifics

The **/dev/random** and **/dev/urandom** devices are created from major and minor numbers assigned by the device configuration subsystem when the random number generator is loaded, so the device names should always be used when attempting to locate or open the devices. The devices are deleted when the random number generator is unloaded. When the system is shut down using the shutdown command, output is taken from the **/dev/urandom** device and is written back to the **/dev/random** device when the random number generator is loaded on the next boot to provide starting entropy to the generator, enhancing the quality of the stored random input after boot.

Input is gathered from interrupt timings when the pool of stored random input falls below half full and continues to be gathered until the pool is again full. This process causes a minor performance impact to all external interrupts while timings are being gathered, which ceases when timings cease to be gathered. Data written to either of the random devices will also contribute to the pool of stored random input and can influence the output, thus writing to these devices should be a privileged operation. This is enforced by the permissions of the devices, so it can be changed by the administrator to be completely disallowed if desired.

## omd Special File

### Purpose

Provides access to the read/write optical device driver.

### Description

The **omd** special file provides block and character (raw) access to disks in the read/write optical drive.

The **r** prefix on a special file name means that the drive is accessed as a raw device rather than a block device. Performing raw I/O with an optical disk requires that all data transfers be in multiples of the optical-disk logical block length. Also, all **Iseek** subroutines that are made to the raw read/write optical device driver must set the file offset pointer to a value that is a multiple of the specified logical block size.

The scdisk SCSI Device Driver provides more information about implementation specifics.

### Read/Write Optical Device Driver

Read/write optical disks, used in read/write optical drives, are media that provide storage for large amounts of data. Block access to optical disks is achieved through the special files `/dev/omd0`, `/dev/omd1`, ... `/dev/omdn`. Character access is provided through the special files `/dev/romd0`, `/dev/romd1`, ... `/dev/romdn`.

When a read/write optical disk is ejected from the drive for a mounted read/write optical file system, the files on the optical disk can no longer be accessed. Before attempting to access these files again, perform the following steps for a file system mounted from the read/write optical disk:

1. Stop processes that have files open on the file system.
2. Move processes that have current directories on the file system.
3. Unmount the file system.
4. Remount the file system after reinserting the media.

If these actions do not work, perform a forced unmount of the file system; then, remount the file system.

**Note:** Reinserting the read/write optical disk will not fix the problem. Stop all processes (graphical and ASCII), and then forcibly unmount the file system. Then remount the file system. After performing this procedure, you can restart any **man** commands.

## Device-Dependent Subroutines

Most read/write optical operations are implemented using the **open**, **read**, **write**, and **close** subroutines. However, for some purposes, use of the **openx** (extended) subroutine is required.

### The **openx** Subroutine

The **openx** subroutine is supported to provide additional functions to the **open** sequence. Appropriate authority is required for execution. If an attempt is made to run the **openx** subroutine without the proper authority, the subroutine returns a value of -1 and sets the **errno** global variable to a value of **EPERM**.

### The **ioctl** Subroutine

The **ioctl** subroutine **IOCINFO** operation returns the **devinfo** structure defined in the `/usr/include/sys/devinfo.h` file. The **IOCINFO** operation is the only operation defined for all device drivers that use the **ioctl** subroutine. Other **ioctl** operations are specific for the type of device driver. Diagnostic mode is not required for the **IOCINFO** operation.

## Error Conditions

Possible **errno** values for **ioctl**, **open**, **read**, and **write** subroutines when using the **omd** special file include:

| Item           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EACCES</b>  | Indicates one of the following circumstances: <ul style="list-style-type: none"><li>• An attempt was made to open a device currently open in Diagnostic or Exclusive Access mode.</li><li>• An attempt was made to open a Diagnostic mode session on a device already open.</li><li>• The user attempted a subroutine other than an <b>ioctl</b> or <b>close</b> subroutine while in Diagnostic mode.</li><li>• A <b>DKIOPCMD</b> operation was attempted on a device not in Diagnostic mode.</li><li>• A <b>DKFORMAT</b> operation was attempted on a device not in Exclusive Access mode.</li></ul> |
| <b>EBUSY</b>   | Indicates one of the following circumstances: <ul style="list-style-type: none"><li>• The target device is reserved by another initiator.</li><li>• An attempt was made to open a session in Exclusive Access mode on a device already opened.</li></ul>                                                                                                                                                                                                                                                                                                                                              |
| <b>EFAULT</b>  | Indicates an illegal user address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EFORMAT</b> | Indicates the target device has unformatted media or media in an incompatible format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## opn Special File

### Purpose

Provides a diagnostic interface to the serial optical ports by way of the Serial Optical Link device driver.

## Description

The **opn** character special file provides strictly diagnostic access to a specific serial optical port. The normal interface to the serial optical link is through the **ops0** special file.

### Related information:

Serial Optical Link Device Handler Overview

## ops0 Special File

### Purpose

Provides access to the serial optical link by way of the Serial Optical Link Device Handler Overview.

### Description

The Serial Optical Link device driver is a component of the Communication I/O subsystem. The device driver can support from one to four serial optical ports. An optical port consists of two separate pieces. The Serial Link Adapter is on the system planar, and is packaged with two to four adapters in a single chip. The Serial Optical Channel Converter plugs into a slot on the system planar and provides two separate optical ports.

The **ops0** special file provides access to the optical port subsystem. An application that opens this special file has access to all the ports, but does not need to be aware of the number of ports available. Each write operation will include a destination processor ID, and the device driver will route the data through the correct port to reach that processor. If there is more than one path to the destination, the device driver will use any link that is available, in case of a link failure.

### Usage Considerations

When accessing the Serial Optical Link device driver, the following should be taken into account:

| Item                                  | Description                                                                                                                            |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| driver initialization and termination | The device driver may be loaded and unloaded. The device driver supports the configuration calls to initialize and terminate itself.   |
| special file support                  | Calls other than the <b>open</b> and <b>close</b> subroutines are discussed based on the mode in which the device driver is operating. |

### Subroutine Support

The Serial Optical Link device driver provides specific support for the **open**, **close**, **read**, and **write** subroutines.

#### open and close Subroutines

The device driver supports the **/dev/ops0** special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). There are no particular considerations for closing the special file. The special file name is used in an **open** call depending on how the device is to be opened. The two types of special file names are:

| Item        | Description                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| /dev/ops0   | Starts the device driver in normal mode.                                                                                                    |
| /dev/ops0/S | Starts the device driver in serialized mode. As a result, the device driver transmits data in the same order in which it receives the data. |

### read Subroutine

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine. For this call, the device driver copies the data into the buffer specified by the caller.

### write Subroutine

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine. For this call, the device driver copies the user data into a kernel buffer and transmits the data.

### Error Codes

The following error codes may be returned when accessing the device driver through the **/dev/ops0** special file:

| Item       | Description                                                                                                                                                                                                                                                                                                           |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EACCES     | Indicates access to the device is denied for one of the following reasons: <ul style="list-style-type: none"> <li>• A non-privileged user tried to open the device in Diagnostic mode.</li> <li>• A kernel-mode user attempted a user-mode call.</li> <li>• A user-mode user attempted a kernel-mode call.</li> </ul> |
| EADDRINUSE | Indicates the network ID is in use.                                                                                                                                                                                                                                                                                   |
| EAGAIN     | Indicates that the transmit queue is full.                                                                                                                                                                                                                                                                            |
| EBUSY      | Indicates one of the following: <ul style="list-style-type: none"> <li>• The device was already initialized.</li> <li>• There are outstanding opens; unable to terminate.</li> <li>• The device is already open in Diagnostic mode.</li> <li>• The maximum number of opens has been exceeded.</li> </ul>              |
| EFAULT     | Indicates that the specified address is not valid.                                                                                                                                                                                                                                                                    |
| EINTR      | Indicates that a system call was interrupted.                                                                                                                                                                                                                                                                         |
| EINVAL     | Indicates that the specified parameter is not valid.                                                                                                                                                                                                                                                                  |
| EIO        | Indicates a general error. If an extension was provided in the call, additional data identifying the cause of the error can be found in the status field.                                                                                                                                                             |
| EMSGSIZE   | Indicates that the data was too large to fit into the receive buffer and that no <i>arg</i> parameter was supplied to provide an alternate means of reporting this error with a status of <b>CIO_BUF_OVFLW</b> .                                                                                                      |
| ENETDOWN   | Indicates that the network is down. The device is unable to process the write.                                                                                                                                                                                                                                        |
| ENOCONNECT | Indicates one of the following: <ul style="list-style-type: none"> <li>• The device is not started.</li> <li>• The processor ID is not connected to the Serial Optical Link subsystem.</li> </ul>                                                                                                                     |
| ENODEV     | Indicates that the specified minor number is not valid.                                                                                                                                                                                                                                                               |
| ENOMEM     | Indicates that the device driver was unable to allocate the required memory.                                                                                                                                                                                                                                          |
| ENOSPC     | Indicates the network ID table is full.                                                                                                                                                                                                                                                                               |
| EPERM      | Indicates that the device is open in a mode that does not allow a Diagnostic-mode open request.                                                                                                                                                                                                                       |

## pty Special File

### Purpose

Provides the pseudo-terminal (pty) device driver.

### Description

The **pty** device driver provides support for a *pseudo-terminal*. A pseudo-terminal includes a pair of *control* and *slave* character devices. The slave device provides processes with essentially the same interface as that provided by the **tty** device driver. However, instead of providing support for a hardware device, the slave device is manipulated by another process through the control half of the pseudo-terminal. That is, anything written on the control device is given to the slave device as input and anything written on the slave device is presented as input on the control device.

In AIX Version 4, the pty subsystem uses naming conventions similar to those from UNIX System V. There is one node for the control driver, **/dev/ptc**, and a maximum number of *N* nodes for the slave drivers, **/dev/pts/n**. *N* is configurable at pty configuration and may be changed dynamically by pty reconfiguration, without closing the opened devices.

The control device is set up as a *clone device* whose major device number is the clone device's major number and whose minor device number is the control driver's major number. There is no node in the filesystem for control devices. A control device can be opened only once, but slave devices can be opened several times.

By opening the control device with the **/dev/ptc** special file, an application can quickly open the control and slave sides of an unused pseudo-terminal. The name of the corresponding slave side can be retrieved using the **ttynode** subroutine, which always returns the name of the slave side.

With Berkeley pty subsystems, commands have to search for an unused pseudo-terminal by opening each control side sequentially. The control side could not be opened if it was already in use. Thus, the opens would fail, setting the **errno** variable to **EIO**, until an unused pseudo-terminal was found. It is possible to configure the pty subsystem in order to use special files with the BSD pty naming convention:

| Item            | Description                  |
|-----------------|------------------------------|
| Control devices | <b>/dev/pty[p-zA-Z][0-f]</b> |
| Slave devices   | <b>/dev/tty[p-zA-Z][0-f]</b> |

These special files are not symbolic links to the operating system special files. They are completely separate. The number of control and slave pair devices using the BSD naming convention is configurable.

The following ioctl commands apply to pseudo-terminals:

| Item             | Description                                                                                                                                                                                  |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TIOCSTOP</b>  | Stops output to a terminal. This is the same as using the Ctrl-S key sequence. No parameters are allowed for this command.                                                                   |
| <b>TIOCSTART</b> | Restarts output that was stopped by a <b>TIOCSTOP</b> command or by the Ctrl-S key sequence. This is the same as typing the Ctrl-Q key sequence. No parameters are allowed for this command. |

| Item                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TIOCPKT</b>            | Enables and disables the packet mode. Packet mode is enabled by specifying (by reference) a nonzero parameter. It is disabled by specifying (by reference) a zero parameter. When applied to the control side of a pseudo-terminal, each subsequent read from the terminal returns data written on the slave part of the pseudo terminal. The data is preceded either by a zero byte (symbolically defined as <b>TIOCPKT_DATA</b> ) or by a single byte that reflects control-status information. In the latter case, the byte is an inclusive OR of zero or more of the following bits: |
| <b>TIOCPKT_FLUSHREAD</b>  | The read queue for the terminal is flushed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>TIOCPKT_FLUSHWRITE</b> | The write queue for the terminal is flushed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>TIOCPKT_STOP</b>       | Output to the terminal is stopped with Ctrl-S.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>TIOCPKT_START</b>      | Output to the terminal is restarted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>TIOCPKT_DOSTOP</b>     | The stop character defined by the current tty line discipline is Ctrl-S; the start character defined by the line discipline is Ctrl-Q.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>TIOCPKT_NOSTOP</b>     | The start and stop characters are not Ctrl-S and Ctrl-Q.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                           | While this mode is in use, the presence of control-status information to be read from the control side can be detected by a select for exceptional conditions.                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                           | This mode is used by the <b>rlogin</b> and <b>rlogind</b> commands to log in to a remote host and implement remote echoing and local Ctrl-S and Ctrl-Q flow control with proper back-flushing of output.                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>TIOCUCNTL</b>          | Enables and disables a mode that allows a small number of simple user <b>ioctl</b> commands to be passed through the pseudo-terminal, using a protocol similar to that of the <b>TIOCPKT</b> mode. The <b>TIOCUCNTL</b> and <b>TIOCPKT</b> modes are mutually exclusive.                                                                                                                                                                                                                                                                                                                 |
|                           | This mode is enabled from the control side of a pseudo-terminal by specifying (by reference) a nonzero parameter. It is disabled by specifying (by reference) a zero parameter. Each subsequent read from the control side will return data written on the slave part of the pseudo-terminal, preceded either by a zero byte or by a single byte that reflects a user control operation on the slave side.                                                                                                                                                                               |
|                           | A user-control command consists of a special ioctl operation with no data. That command is issued as <b>UIOCCMD</b> ( <i>Value</i> ), where the <i>Value</i> parameter specifies a number in the range 1 through 255. The operation value is received as a single byte on the next read from the control side.                                                                                                                                                                                                                                                                           |
|                           | A value of 0 can be used with the <b>UIOCCMD</b> ioctl operation to probe for the existence of this facility. The zero is not made available for reading by the control side. Command operations can be detected with a select for exceptional conditions.                                                                                                                                                                                                                                                                                                                               |
| <b>TIOCREMOTE</b>         | A mode for the control half of a pseudo-terminal, independent of <b>TIOCPKT</b> . This mode implements flow control, rather than input editing, for input to the pseudo-terminal, regardless of the terminal mode. Each write to the control terminal produces a record boundary for the process reading the terminal. In normal usage, a write of data is like the data typed as a line on the terminal, while a write of zero bytes is like typing an end-of-file character. This mode is used for remote line editing in a window-manager and flow-controlled input.                  |

## rcm Special File

### Purpose

Provides the application interface to obtain and relinquish the status of a graphics process through the **Rendering Context Manager (RCM)** device driver.

## Description

The **rcm** is used by graphics systems to obtain a **gsc\_handle**. This handle is required in the call to **aixgsc** which is part of the procedure of becoming a graphics process.

## Usage Considerations

The RCM device driver supports **open**, **close**, and **ioctl** subroutines.

A application uses the GSC\_HANDLE ioctl command to get a **gsc\_handle** as part of becoming a graphics process. When it closes **rcm**, either normally, or by abnormal termination, the RCM releases any displays which it owns. This is implemented as a LFT\_REL\_DISP ioctl command to the LFT device driver.

| Item               | Description                                                  |
|--------------------|--------------------------------------------------------------|
| IOCINFO            | Returns <b>devinfo</b> structure.                            |
| GSC_HANDLE         | Returns a <b>gsc_handle</b> .                                |
| RCM_SET_DIAG_OWNER | Obtain exclusive use of the display adapter for diagnostics. |

## rhdisk Special File

### Purpose

Provides raw I/O access to the physical volumes (fixed-disk) device driver.

## Description

The **rhdisk** special file provides raw I/O access and control functions to physical-disk device drivers for physical disks. Raw I/O access is provided through the **/dev/rhdisk0**, **/dev/rhdisk1**, ..., character special files.

Direct access to physical disks through block special files should be avoided. Such access can impair performance and also cause data consistency problems between data in the block I/O buffer cache and data in system pages. The **/dev/hdisk** block special files are reserved for system use in managing file systems, paging devices and logical volumes.

The **r** prefix on the special file name indicates that the drive is to be accessed as a raw device rather than a block device. Performing raw I/O with a fixed disk requires that all data transfers be in multiples of the disk block size. Also, all **lseek** subroutines that are made to the raw disk device driver must result in a file-pointer value that is a multiple of the disk-block size.

## Usage Considerations

**Note:** Data corruption, loss of data, or loss of system integrity (system crashes) will occur if devices supporting paging, logical volumes, or mounted file systems are accessed using block special files. Block special files are provided for logical volumes and disk devices on the operating system and are solely for system use in managing file systems, paging devices, and logical volumes. They should not be used for other purposes.

### open and close Subroutines

The **openx** subroutine provides additional functions to the open sequence. This subroutine requires appropriate permission to execute. Attempting to do so without the proper permission results in a return value of -1, with the **errno** global variable set to **EPERM**.

## read and write Subroutines

The **readx** and **writex** subroutines provide for additional parameters affecting the raw data transfer. The *ext* parameter specifies certain options that apply to the request being made. The options are constructed by logically ORing zero or more of the following values.

**Note:** The following operations can be used only with the **writex** subroutine.

| Item      | Description                                                                                                                                                                                                                                                |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WRITEV    | Perform physical write verification on this request.                                                                                                                                                                                                       |
| HWRELOC   | Perform hardware relocation of the specified block before the block is written. This is done only if the drive supports safe relocation. Safe relocation ensures that once the relocation is started, it will complete safely regardless of power outages. |
| UNSAFEREL | Perform hardware relocation of the specified block before the block is written. This is done if the drive supports any kind of relocation (safe or unsafe).                                                                                                |

## ioctl Subroutine

Only one ioctl operation, **IOCINFO**, is defined for all device drivers that use the **ioctl** subroutine. The remaining ioctl operations are all specific to physical-disk devices. Diagnostic mode is not required for the **IOCINFO** operation.

The **IOCINFO** ioctl operation returns a structure for a device type of **DD\_DISK**. This structure is defined in the */usr/include/sys/devinfo.h* file.

## Error Codes

In addition to the errors listed for the **ioctl**, **open**, **read**, and **write** subroutines, the following other error codes are also possible:

| Item   | Description                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------|
| EACCES | An <b>open</b> subroutine call has been made to a device in Diagnostic mode.                                                   |
| EACCES | A diagnostic <b>openx</b> subroutine call has been made to a device already opened.                                            |
| EACCES | A diagnostic ioctl operation has been attempted when not in Diagnostic mode.                                                   |
| EINVAL | An <i>nbyte</i> parameter to a <b>read</b> or <b>write</b> subroutine is not a multiple of the disk block size.                |
| EINVAL | An unsupported ioctl operation has been attempted.                                                                             |
| EINVAL | An unsupported <b>readx</b> or <b>writex</b> subroutine has been attempted.                                                    |
| EMEDIA | The target device has indicated an unrecovered media error.                                                                    |
| ENXIO  | A parameter to the <b>ioctl</b> subroutine is invalid.                                                                         |
| ENXIO  | A <b>read</b> or <b>write</b> subroutine has been attempted beyond the end of the disk.                                        |
| EIO    | The target device cannot be located or is not responding.                                                                      |
| EIO    | The target device has indicated an unrecovered hardware error.                                                                 |
| EMFILE | An <b>open</b> subroutine has been attempted for an adapter that already has the maximum permissible number of opened devices. |
| EPERM  | The caller lacks the appropriate privilege.                                                                                    |

## Files

| Item                                      | Description                                                                  |
|-------------------------------------------|------------------------------------------------------------------------------|
| /dev/hdisk0, /dev/hdisk1, ... /dev/hdiskn | Provide block I/O access to the physical volumes (fixed-disk) device driver. |

Direct Access Storage Device (DASD) Overview

scdisk SCSI Device Driver

## rmt Special File

### Purpose

Provides access to the sequential-access bulk storage medium device driver.

### Description

Magnetic tapes are used primarily for backup, file archives, and other off-line storage. Tapes are accessed through the /dev/rmt0, ... , /dev/rmt255 special files. The r in the special file name indicates *raw* access through the character special file interface. A tape device does not lend itself well to the category of a block device. Thus, only character interface special files are provided.

Special files associated with each tape device determine which action is taken during open or close operations. These files also dictate, for applicable devices, at what density data is to be written to tape. The following table shows the names of these special files and their corresponding characteristics:

*Table 34. Tape Drive Special File Characteristics*

| Special File Name | Characteristics                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| /dev/rmt*         | <b>Rewind-on-Close</b><br>Yes<br><br><b>Retention-on-Open</b><br>No<br><br><b>Bytes per Inch</b><br>Density setting #1  |
| /dev/rmt*.1       | <b>Rewind-on-Close</b><br>No<br><br><b>Retention-on-Open</b><br>No<br><br><b>Bytes per Inch</b><br>Density setting #1   |
| /dev/rmt*.2       | <b>Rewind-on-Close</b><br>Yes<br><br><b>Retention-on-Open</b><br>Yes<br><br><b>Bytes per Inch</b><br>Density setting #1 |

*Table 34. Tape Drive Special File Characteristics (continued)*

| Special File Name | Characteristics                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| /dev/rmt*.3       | <b>Rewind-on-Close</b><br>No<br><br><b>Retention-on-Open</b><br>Yes<br><br><b>Bytes per Inch</b><br>Density setting #1  |
| /dev/rmt*.4       | <b>Rewind-on-Close</b><br>Yes<br><br><b>Retention-on-Open</b><br>No<br><br><b>Bytes per Inch</b><br>Density setting #2  |
| /dev/rmt*.5       | <b>Rewind-on-Close</b><br>No<br><br><b>Retention-on-Open</b><br>No<br><br><b>Bytes per Inch</b><br>Density setting #2   |
| /dev/rmt*.6       | <b>Rewind-on-Close</b><br>Yes<br><br><b>Retention-on-Open</b><br>Yes<br><br><b>Bytes per Inch</b><br>Density setting #2 |
| /dev/rmt*.7       | <b>Rewind-on-Close</b><br>No<br><br><b>Retention-on-Open</b><br>Yes<br><br><b>Bytes per Inch</b><br>Density setting #2  |

1. The values of density setting #1 and density setting #2 come from tape drive attributes that can be set using SMIT. Typically density setting #1 is set to the highest possible density for the tape drive while density setting #2 is set to a lower density. However, density settings are not required to follow this pattern.
2. The density value (bytes per inch) is ignored when using a magnetic tape device that does not support multiple densities. For tape drives that do support multiple densities, the density value only applies when writing to the tape. When reading, the drive defaults to the density at which the tape is written.
3. Most tape drives use 512-byte block size. The 8mm tape drive uses a minimum block size of 1024 bytes. Using SMIT to lower the block size, will waste space.

## Usage Considerations

Most tape operations are implemented using the **open**, **read**, **write**, and **close** subroutines. However, for diagnostic purposes, the **openx** subroutine is required.

### open and close Subroutines

Care should be taken when closing a file after writing. If the application reverses over the data just written, no file marks will be written. However, for tape devices that allow for block update, unless the application spaces in the reverse direction or returns the tape position to the beginning of tape (BOT), one or two file marks will be written upon closing the device. (The number of file marks depends on the special file type.)

For multtape jobs, the special file must be opened and closed for each tape. The user is not allowed to continue if the special file is opened and the tape has been changed.

The **openx** subroutine is intended primarily for use by the diagnostic commands and utilities. Appropriate authority is required for execution. Executing this subroutine without the proper authority results in a return value of -1, with the **errno** global variable set to **EPERM**.

### **read and write Subroutines**

When opened for reading or writing, the tape is assumed to be positioned as desired. When the tape is opened as no-rewind-on-close (**/dev/rmt\***.1) and a file is written, a single file mark is written upon closing the tape. When the tape is opened as rewind-on-close (**/dev/rmt\***) and a file is written, a double file mark is written upon closing the tape. When the tape is opened as no-rewind-on-close and reads from a file, the tape is positioned upon closing after the end-of-file (EOF) mark following the data just read.

By specifically choosing the **rmt** file, it is possible to create multiple file tapes.

Although tapes are accessed through character interface special files, the number of bytes required by either a read or write operation must be a multiple of the block size defined for the magnetic tape device. When the tape drive is in variable block mode, read requests for less than the tape's block size return the number of bytes requested and set the **errno** global variable to a value of 0. In this case, the **readx** subroutine's *Extension* parameter must be set to **TAPE\_SHORT\_READ**.

During a read, the record size is returned as the number of bytes read, up to the buffer size specified. If an EOF condition is encountered, then a zero-length read is returned, with the tape positioned after the EOF.

An end-of-media (EOM) condition encountered during a read or write operation results in the return of the number of bytes successfully ready or written. When a write is attempted after the device has reached the EOM, a value of -1 is returned with the **errno** global variable set to the **ENXIO** value. When a read is attempted after the device has reached the EOM, a zero-length read is returned. Successive reads continue to return a zero-length read.

**Data Buffering With a Tape Device:** Some tape devices contain a data buffer to maximize data transfer speed when writing to tape. A write operation sent to tape is returned as complete when the data is transferred to the data buffer of the tape device. The data in the buffer is then written to tape asynchronously. As a result, data-transfer speed increases since the host need not wait for I/O completion.

Two modes are provided by the tape device driver to facilitate use of these data buffers. The non-buffered mode causes writes to tape to bypass the data buffer and go directly to tape. In buffered mode, all write subroutines are returned as complete when the transfer data has been successfully written to the tape device buffer. The device driver does not flush the data buffer until the special file is closed or an EOM condition is encountered.

If an EOM condition is encountered while running in buffered mode, the device attempts to flush the device data buffer. The residual count can exceed the write transfer length in buffered mode. In some cases, the flushing of residual data may actually run the tape off the reel. Either case is considered a failure and results in a return value of -1, with the **errno** global variable set to **EIO**. These errors can require the user to run in non-buffered mode.

**rmt Special File Considerations:** Failures that result in a device reset while reading or writing to tape require the special file to be closed and the job restarted. Any commands issued after this condition occurs and until the special file is closed result in a return value of -1, with the **errno** global variable set to **EIO**. Non-reset type errors (that is, media or hardware errors) result in the tape being left positioned where the error occurred.

For multi-tape jobs, the special file must be opened and closed for each tape. The user is not allowed to continue if the special file is opened and the tape has been changed.

A signal received by the tape device driver will cause the current command to abort. As a result, the application halts time-consuming commands (for instance, an erase operation) without recycling the drive power or waiting for a timeout to occur.

Use of zero (0) as a block-size parameter indicates the blocksize is of variable length.

### ioctl Subroutine

A single ioctl operation, **IOCINFO**, is defined for all device drivers that use the **ioctl** subroutine. For the **rmt** special file, the **STIOCTOP** operation has also been defined.

**The IOCINFO ioctl operation:** The **IOCINFO** ioctl operation returns a structure defined in the **/usr/include/sys/devinfo.h** file.

**The STIOCTOP ioctl operation:** The **STIOCTOP** ioctl operation provides for command execution operations, such as erase and retension. The parameter to the **ioctl** subroutine using the **STIOCTOP** operation specifies the address of a **stop** structure, as defined in the **/usr/include/sys/tape.h** file.

The operation found in the **st\_op** field in the **stop** structure is performed **st\_count** times, except for rewind, erase, and retension operations. The available operations are:

| Item           | Description                                                                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>STREW</b>   | Rewind.                                                                                                                                                                                                                                                                                                                                      |
| <b>STOFFL</b>  | Rewind and unload the tape. A tape must be inserted before the device can be used again.                                                                                                                                                                                                                                                     |
| <b>STERASE</b> | Erase tape; leave at load point.                                                                                                                                                                                                                                                                                                             |
| <b>STRETEN</b> | Retension tape; leave at load point.                                                                                                                                                                                                                                                                                                         |
| <b>STWEOF</b>  | Write and end-of-file mark.                                                                                                                                                                                                                                                                                                                  |
| <b>STFSF</b>   | Forward space file.                                                                                                                                                                                                                                                                                                                          |
| <b>STFSR</b>   | Forward space record.                                                                                                                                                                                                                                                                                                                        |
| <b>STRSF</b>   | Reverse space file.                                                                                                                                                                                                                                                                                                                          |
| <b>STRSR</b>   | Reverse space record.                                                                                                                                                                                                                                                                                                                        |
| <b>STDEOF</b>  | Disable end-of-file check.<br><b>Note:</b> Use of the <b>STDEOF</b> command enables an application to write beyond the end of the tape. When disabling end-of-file checking by issuing the <b>STDEOF</b> command, it is the responsibility of the application to guard against error conditions that can arise from the use of this command. |

**Note:** Execution of the preceding commands depends on the particular tape device and which commands are supported. If the command is not supported on a particular device, a value of -1 is returned, with the **errno** global variable set to **EINVAL**.

### Error Codes

In addition to general error codes listed for **ioctl**, **open**, **read**, and **write** subroutines, the following specific error codes may also occur:

| Item       | Description                                                                                                                                         |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| EAGAIN     | An open operation was attempted to a device that is already open.                                                                                   |
| EBUSY      | The target device is reserved by another initiator.                                                                                                 |
| EINVAL     | O_APPEND is supplied as a mode in which to open.                                                                                                    |
| EINVAL     | An <i>nbyte</i> parameter to a <b>read</b> or <b>write</b> subroutine is not an even multiple of the blocksize.                                     |
| EINVAL     | A parameter to the <b>ioctl</b> subroutine is invalid.                                                                                              |
| EINVAL     | The requested ioctl operation is not supported on the current device.                                                                               |
| EIO        | Could not space forward or reverse <i>st_count</i> records before encountering an EOM condition or a file mark.                                     |
| EIO        | Could not space forward or reverse <i>st_count</i> file marks before encountering an EOM condition.                                                 |
| EMEDIA     | The tape device has encountered an unrecoverable media error.                                                                                       |
| ENOMEM     | The number of bytes requested for a read of a variable-length record on tape is less than the actual size (in bytes) of the variable-length record. |
| ENOTREADY  | There is no tape in the drive or the drive is not ready.                                                                                            |
| ENXIO      | A write operation was attempted while the tape was at the EOM.                                                                                      |
| EPERM      | The requested subroutine requires appropriate authority.                                                                                            |
| ETIMEDOUT  | A command has timed out.                                                                                                                            |
| EWRPROTECT | An open operation for read/write was attempted on a read-only tape.                                                                                 |
| EWRPROTECT | An ioctl operation that effects media was attempted on a read-only tape.                                                                            |

## scsi Special File

### Purpose

Provides access to the SCSI adapter driver.

### Description

The **scsi** special file provides an interface to an attached SCSI adapter. This special file should not be opened directly by application programs (with the exception of diagnostics applications). The **/dev/scsi0**, **/dev/scsi1**, ... **/dev/scsin** files are the **scsi** special files.

The description of the SCSI Adapter device driver in *Technical Reference: Kernel and Subsystems, Volume 1* provides the implementation specifics for the SCSI adapter.

scdisk subroutine

## secvars.cfg File

### Purpose

Consists of configuration values for various system security properties.

## Description

The `/etc/secvars.cfg` file is a stanza file, where each stanza name represents a security property. The `lssec` and the `chsec` commands can be used to view and modify the files. The stanza contains the following stanza names:

### groups

Defines the behavior of groups on the system. This stanza has the following attributes:

#### Domainlessgroups

Controls the system configuration for merging the user's group attributes from Lightweight Directory Access Protocol (LDAP) and files domains. Only the files and the LDAP modules are supported. Following values are valid for the `domainlessgroups` attribute.

**True** When this attribute is set to true, a user can be assigned groups from both the LDAP and files domains simultaneously irrespective of user's domain. The user must belong to either the LDAP or file domains.

For example, the users that are defined on the LDAP can be assigned the local groups and vice versa.

**False** When this attribute is set to false, the users can be assigned groups only from the domain where the user definition exists. The default value is false.

#### Notes:

1. If the LDAP server is down or not reachable, and this variable is set to `true`, some operations on groups and users fail. If this variable is set to `true`, it mandates a properly functioning LDAP server. For example, when the LDAP server is not reachable, the `rmgroup` for local groups fails because these groups can be a primary group to an LDAP user. Also, if the LDAP server is not reachable, a local user with an LDAP group, as primary group fails to login.
2. You must not have same names or IDs for the users or groups across LDAP and local (files) domains when this variable is set to `true`, because the behavior of some commands is unpredictable. To avoid creation of same ID, set the `dist_uniqid` system attribute.
3. When the LDAP server is not reachable, the `lsvuser` and `lsgroup` commands displays information from the local systems.
4. Adding a local user to an LDAP group effectively makes that user belong to the LDAP group not only on the current host, but also on any other host where the user with the same name exists locally. In other words, if a user with the same name exists locally on two or more hosts, adding that user to an LDAP group from one host makes it effective on the other host.
5. When local user is removed from the system, it is automatically removed from an LDAP group. This means that, when a local user that has the same name across two or more hosts is removed from an LDAP group from one host, all the local users with the same name across all the other hosts lose their membership from that LDAP group.
6. When a user is assigned to a group, a user with same name exists in the other domain, the user that gets assigned to the group is the one from the same domain as the group.

#### Example: specifying similar names to users or groups, across domains

```
User "user1" is present in the LDAP domain.
mkuser -R LDAP id=10001 user1
```

```
Another user also named "user1" is present in the local domain.
mkuser -R files id=1000 user1
```

```
Ldgrp1's user user1 belongs to the LDAP domain.
mkgroup -R LDAP id=20001 users=user1 Ldgrp1
```

7. When an LDAP group is assigned as a primary group to a local user on one client or host, the group can be removed from another host. This is possible because the second host does not have any knowledge about the local users on the first client.
8. If this feature is turned on, user validation is skipped while creating or modifying groups. For example:  

```
chgroup users=user1,user2,user3 group_name
```

users user1, user2, and user3 are not checked for their existence.  
Also, a group existing locally on one LDAP client cannot be assigned to users from another LDAP client.
9. The root user cannot be assigned LDAP groups irrespective of the value of the **domainlessgroups** attribute.
10. For the **domainlessgroups** feature to work properly, the user map files under `/etc/security/ldap` directory must contain the mapping for the **pgid** attribute.
11. You must ensure that LDAP client daemon and LDAP server are up and running before you delete a local user or a local group. Otherwise the entry of such a local user or a local group continues to exist in the LDAP.

## **Stanza-Variable association table**

This stanza has the following attributes:

| <b>Stanza</b> | <b>Variable</b>  |
|---------------|------------------|
| groups        | domainlessgroups |

## **Security**

### **Access Control**

These files grants read and write access to the root user. Access for other users and groups depends on the security policy for the system.

## **Files**

| <b>Item</b>                      | <b>Description</b>                          |
|----------------------------------|---------------------------------------------|
| <code>/etc/secvars.cfg</code>    | Specifies the path to the file.             |
| <code>/etc/group</code>          | Contains the basic attributes of groups.    |
| <code>/etc/security/group</code> | Contains the extended attributes of groups. |

## **Examples**

An example of the group stanza is follows:

```
groups:
 domainlessgroups=true
```

## **tablet Special File**

### **Purpose**

Provides access to the tablet.

## Description

The tablet special file is the application interface to the tablet. It provides the applications with the capability of receiving input from the tablet and it allows the application to change the sampling rate, dead zones, origin, resolution, and conversion mode.

## Configuration

There are no user commands to change the configuration of the tablet device. Applications may use **ioctl** commands to modify the configuration but these modifications are effective only until the tablet is closed.

## Usage Considerations

The **open** subroutine call specifying the **tablet** special file is processed normally except that the *Oflag* and *Mode* parameters are ignored. The open request is rejected if the special file is already opened or if a kernel extension attempts to open the special file. All tablet inputs are flushed following an **open** subroutine call until an input ring is established. The tablet device is reset to the default configuration when an open request is made.

The **tablet** special file does not support the **read** or **write** subroutine calls. Instead, input data is obtained from the tablet through the input ring. The **read** and **write** subroutine calls behave the same as **read** or **write** subroutine calls to the **/dev/null** file.

The **tablet** special file supports the following functions with **ioctl** subroutines:

| Item                 | Description                       |
|----------------------|-----------------------------------|
| <b>IOCINFO</b>       | Returns <b>devinfo</b> structure. |
| <b>TABCONVERSION</b> | Sets tablet conversion mode.      |
| <b>TABDEADZONE</b>   | Sets tablet dead zones.           |
| <b>TABFLUSH</b>      | Flushes input ring.               |
| <b>TABORIGIN</b>     | Sets tablet origin.               |
| <b>TABQUERYID</b>    | Queries tablet device identifier. |
| <b>TABREGRING</b>    | Registers input ring.             |
| <b>TABRESOLUTION</b> | Sets resolution.                  |
| <b>TABSAMPLERATE</b> | Sets sample rate.                 |

## Error Codes

The error codes can be found in the **/usr/include/sys/errno.h** file.

| Item          | Description                                                            |
|---------------|------------------------------------------------------------------------|
| <b>EFAULT</b> | Indicates insufficient authority to access address or invalid address. |
| <b>EIO</b>    | Indicates an I/O error.                                                |
| <b>ENOMEM</b> | Indicates insufficient memory for required paging operation.           |
| <b>ENOSPC</b> | Indicates insufficient file system or paging space.                    |
| <b>EINVAL</b> | Indicates an invalid argument.                                         |
| <b>EINTR</b>  | Indicates the request was interrupted by signal.                       |
| <b>EPERM</b>  | Indicates a permanent error occurred.                                  |
| <b>EBUSY</b>  | Indicates the device is busy.                                          |
| <b>ENXIO</b>  | Indicates an unsupported device number was specified.                  |
| <b>ENODEV</b> | Indicates an unsupported device or device type mismatch.               |
| <b>EACCES</b> | Indicates <b>open</b> is not allowed.                                  |

## Files

| Item                       | Description                                                            |
|----------------------------|------------------------------------------------------------------------|
| /usr/include/sys/inputdd.h | Contains declarations for ioctl commands and input ring report format. |

## tap Special File

### Purpose

Provides software network interface which is Ethernet tunnel.

### Description

The **tap** interface is a software loopback mechanism. It is a network interface analog of the pseudoterminal (**pty**).

The tap driver, like the **pty** driver, provides two interfaces: a simulating interface (an Ethernet interface for **tap** or a terminal for **pty**) and a character-special device, the *control* interface.

The network interfaces are named as *tap0*, *tap1*, and so on, one for each open control device that has been opened. These Ethernet network interfaces persist until the **if\_tap.ko** module is unloaded or until removed with the **ifconfig destroy** command.

The **tap** devices are created by using interface cloning with the **ifconfig tapN create** command. This is the preferred method for creating the **tap** devices. You can remove of interfaces by using the **ifconfig tapN destroy** command.

Each interface supports the usual Ethernet network interface ioctl, such as **SIOCSIFADDR** and **SIOCSIFNETMASK**, and thus can be used with the **ifconfig** command like any other Ethernet interface. When the system chooses to transmit an Ethernet frame on the network interface, the frame can be read from the control device. It appears as input there. The process of writing an Ethernet frame to the control device generates an input frame on the network interface, as if the (nonexistent) hardware had just received it.

The Ethernet tunnel device, normally */dev/tapN*, is exclusive-open (it cannot be opened if it is already open), and is restricted to the super-user or users with the **PV\_NET\_CNTL** privilege. The tunnel device is not marked **up** when the control device is opened. A **read()** call returns an error (**EHOSTDOWN**) if the interface is not ready. After the interface is ready, the **read()** call returns an Ethernet frame, if any frame is available. In case the frame is not available, it either blocks until one frame is available or returns an **EWOULDBLOCK** error, depending on whether the nonblocking I/O has been enabled. If the frame is longer than is allowed in the buffer passed to the **read()** call, the extra data is dropped.

A **write(2)** call passes an Ethernet frame to be received on the pseudointerface. Each **write()** call supplies exactly one frame. The frame length is taken from the amount of data provided to the **write()** call. If the frame cannot be accepted for a transient reason (for example, no buffer space is available), the **write()** call is not block, but is dropped. However, if the reason is not transient (for example, the frame is too large), an error is returned.

The following ioctl calls are supported and are defined in the **<net/if\_tap.h>** file:

| Item       | Description                                                                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TAPSIFINFO | Sets the network interface information (line speed, MTU, and type). The argument should be a pointer to the <b>struct tapinfo</b> parameter.                                                              |
| TAPGIFINFO | Retrieves the network interface information, such as line speed, MTU, and type. The argument should be a pointer to a <b>struct tapinfo</b> parameter.                                                    |
| TAPSDEBUG  | Sets the internal debugging variable to that value. The argument should be a pointer to an <b>int</b> variable.                                                                                           |
| TAPGDEBUG  | Stores the internal debugging variable's value into it. The argument should be a pointer to an <b>int</b> variable.                                                                                       |
| TAPGIFNAME | Retrieves the network interface name. The argument should be a pointer to the <b>struct ifreq</b> parameter. The interface name is returned in the <b>ifr_name</b> field.                                 |
| FIONBIO    | Turns nonblocking I/O for read operation off or on, depending on whether the value of the <b>int</b> argument is zero. Write operation are always nonblocking.                                            |
| FIOASYNC   | Turns asynchronous I/O for read operation (that is generation of the <b>SIGIO</b> signal when data is available to be read) off or on, depending on whether the value of the <b>int</b> argument is zero. |
| FIONREAD   | Stores the size of the first one into the <b>int</b> argument if any frames are queued to be read; otherwise, stores zero..                                                                               |
| TIOCSPGRP  | Sets the process group to receive the <b>SIGIO</b> signals, when asynchronous I/O is enabled, to the <b>int</b> argument value.                                                                           |
| TIOCGPGRP  | Retrieves the process group value for the <b>SIGIO</b> signals into the argument <b>int</b> value.                                                                                                        |

The control device also supports the `select()` call for a read operation. Although the `write()` call is supported, it is rarely chosen. The `write()` call always succeeds because write operations are nonblocking. On the last close operation of the data device, the interface is brought down (as if with the `ifconfig tapN down`). All the queued frames are thrown away. If the interface is up when the data device is not open, output frames are thrown away to avoid piling up.

`tty` Subsystem Overview

## tmscsi Special File

### Purpose

Provides access to the SCSI **tmscsi** device driver.

### Description

The **tmscsi** special file provides an interface to allow processor-to-processor data transfer using the SCSI `send` command. This single device driver handles both SCSI initiator and SCSI target mode roles.

The user accesses the data transfer functions through the special files `/dev/tmsci0.xx`, `/dev/tmsci1.xx`, .... These are all character special files. The `xx` variable can be either **im**, initiator-mode interface, or **tm**, target-mode interface. The initiator-mode interface transmits data, and the target-mode interface receives data.

The least significant bit of the minor device number indicates to the device driver which mode interface is selected by the caller. When the least significant bit of the minor device number is set to 1, the target-mode interface is selected. When the least significant bit is set to 0, the initiator-mode interface is selected.

When the caller opens the initiator-mode special file, a logical path is established allowing data to be transmitted. The `write`, `writex`, `writev`, or `writevx` subroutine initiates data transmission for a user-mode caller, and the `fp_write` or `fp_rwuio` kernel services initiate data transmission for a kernel-mode caller. The SCSI target-mode device driver then builds a SCSI `send` command to describe the transfer, and the data is sent to the device. Once the write entry point returns, the calling program can access the transmit buffer.

When the caller opens the target-mode special file, a logical path is established allowing data to be received. The **read**, **readx**, **readv**, or **readvx** subroutine initiates data reception for a user-mode caller, and the **fp\_read** or **fp\_rwuio** kernel service initiates data reception for a kernel-mode caller. The SCSI target-mode device driver then returns data received for the application.

**Note:** This operation is not supported by all SCSI I/O controllers.

SCSI Target-Mode Overview

## **tokn Special File**

### **Purpose**

Provides access to the token-ring adapters by way of the token-ring device handler.

### **Description**

The **tokn** character special file provides access to the token-ring device handler that provides access to a token-ring local area network. The device handler supports up to four token-ring adapters.

### **Usage Considerations**

When accessing the token-ring device handler, the following should be taken into account:

#### **Driver initialization and termination**

The device handler may be loaded and unloaded. The device handler supports the configuration calls to initialize and terminate itself.

#### **Special file support**

Calls other than the **open** and **close** subroutines are discussed based on the mode in which the device handler is operating.

#### **Subroutine Support**

The token-ring device handler provides specific support for the **open**, **close**, **read**, and **write** subroutines.

##### **open and close Subroutines**

The device handler supports the **/dev/tokn** special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). There are no particular considerations for closing the special file. The special file name used in an **open** call depends upon how the device is to be opened. The three types of special file names are:

| Item        | Description                                                                                                                 |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|
| /dev/tokn   | Starts the device handler for the selected port, where the value of <i>n</i> is $0 \leq n \leq 7$ .                         |
| /dev/tokn/D | Starts the device handler for the selected port in Diagnostic mode, where the value of <i>n</i> is $0 \leq n \leq 7$ .      |
| /dev/tokn/W | Starts the device handler for the selected port in Diagnostic Wrap mode, where the value of <i>n</i> is $0 \leq n \leq 7$ . |

## read Subroutine

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine. For this call, the device handler copies the data into the buffer specified by the caller.

## write Subroutine

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine. For this call, the device handler copies the user data into a kernel buffer and transmits the data on the LAN.

## Error Conditions

The following error conditions may be returned when accessing the device handler through the **dev/tokn** special file:

| Item        | Description                                                                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EACCES      | Indicates that permission to access the adapter is denied for one of the following reasons: <ul style="list-style-type: none"> <li>Device has not been configured.</li> <li>Diagnostic mode open request denied.</li> <li>The call is from a kernel-mode process.</li> </ul>                                   |
| EAGAIN      | Indicates that the transmit queue is full.                                                                                                                                                                                                                                                                     |
| EBUSY       | Indicates one of the following: <ul style="list-style-type: none"> <li>The device is already opened in Diagnostic mode.</li> <li>The maximum number of opens has already been reached.</li> <li>The request is denied.</li> <li>The device is in use.</li> <li>The device handler cannot terminate.</li> </ul> |
| EEXIST      | Indicates that the device is already configured or the device handler is unable to remove the device from switch table.                                                                                                                                                                                        |
| EFAULT      | Indicates that an invalid address or parameter was specified.                                                                                                                                                                                                                                                  |
| EINTR       | Indicates that the subroutine was interrupted.                                                                                                                                                                                                                                                                 |
| EINVAL      | Indicates one of the following: <ul style="list-style-type: none"> <li>The parameters specified were invalid.</li> <li>The define device structure (DDS) is invalid.</li> <li>The device handler is not in Diagnostic mode.</li> </ul>                                                                         |
| ENOCONNECT  | Indicates that the device has not been started.                                                                                                                                                                                                                                                                |
| ENETDOWN    | Indicates that the network is down and the device handler is unable to process the command.                                                                                                                                                                                                                    |
| ENOENT      | Indicates that there was no DDS available.                                                                                                                                                                                                                                                                     |
| ENOMEM      | Indicates that the device handler was unable to allocate required memory.                                                                                                                                                                                                                                      |
| ENOMSG      | Indicates that there was no message of desired type.                                                                                                                                                                                                                                                           |
| ENOSPC      | Indicates that the network ID table is full or the maximum number of opens was exceeded.                                                                                                                                                                                                                       |
| EADDRINUSE  | Indicates that the specified network ID is in use.                                                                                                                                                                                                                                                             |
| ENXIO       | Indicates that the specified minor number was not valid.                                                                                                                                                                                                                                                       |
| ENETUNREACH | Indicates that the device handler is in Network Recovery mode and is unable to process the write operation.                                                                                                                                                                                                    |
| EMSGSIZE    | Indicates that the data is too large for the supplied buffer.                                                                                                                                                                                                                                                  |

## **trace Special File**

### **Purpose**

Supports event tracing.

### **Description**

The **/dev/systrace** and **/dev/systrcctl** special files support the monitoring and recording of selected system events. Minor device 0 of the **trace** drivers is the interface between processes that record trace events and the trace daemon. Write trace events to the **/dev/systrace** file by the **trchk** and **trcgen** subroutines and the **trcgenk** kernel service. Minor devices 1 through 7 of the **trace** drivers support generic trace channels for tracing system activities such as communications link activities.

The **trace** special file is part of Software Trace Service Aids package.

#### **Related information:**

**trcgenk** subroutine

RAS Kernel Services

## **tty Special File**

### **Purpose**

Supports the controlling terminal interface.

### **Description**

For each process, the **/dev/tty** special file is a synonym for the controlling terminal associated with that process. By directing messages to the **tty** file, application programs and shell sequences can ensure that the messages are written to the terminal even if output is redirected. Programs can also direct their display output to this file so that it is not necessary to identify the active terminal.

A terminal can belong to a process as its controlling terminal. Each process of a session that has a controlling terminal has the same controlling terminal. A terminal can be the controlling terminal for one session at most. If a session leader has no controlling terminal and opens a terminal device file that is not already associated with a session (without using the **O\_NOCTTY** option of the **open** subroutine), the terminal becomes the controlling terminal of the session leader. If a process that is not a session leader opens a terminal file or if the **O\_NOCTTY** option is used, that terminal does not become the controlling terminal of the calling process. When a controlling terminal becomes associated with a session, its foreground process group is set to the process group of the session leader.

The controlling terminal is inherited by a child process during a **fork** subroutine. A process cannot end the association with its controlling terminal by closing all of its file descriptors associated with the controlling terminal if other processes continue to have the terminal file open. A process that is not already the session leader or a group leader can break its association with its controlling terminal by using the **setsid** subroutine. Other processes remaining in the old session retain their association with the controlling terminal.

When the last file descriptor associated with a controlling terminal is closed (including file descriptors held by processes that are not in the controlling terminal's session), the controlling terminal is disassociated from its current session. The disassociated controlling terminal can then be acquired by a new session leader.

A process can also remove the association it has with its controlling terminal by opening the **tty** file and issuing the following **ioctl** command:

```
ioctl (FileDescriptor, TIOCNOTTY, 0);
```

It is often useful to disassociate server processes from their controlling terminal so they cannot receive input from or be stopped by the terminal.

This device driver also supports the POSIX and Berkeley line disciplines.

tty Subsystem Overview

## **urandom and random Devices**

### **Purpose**

Source of secure random output.

### **Description**

The **/dev/random** and **/dev/urandom** character devices provide cryptographically secure random output generated from interrupt timings or input written to the devices.

The **/dev/random** device is intended to provide high quality, cryptographically secure random output and will only return output for which sufficient (an equal or greater amount) random input is available to generate the output. If insufficient random input is available, reads from the **/dev/random** device will block until the request can be fulfilled unless the O\_NONBLOCK flag was specified when the device was opened, in which case as much high quality output as could be generated is returned with the error code EAGAIN.

The **/dev/urandom** device provides a reliable source of random output, however the output will not be generated from an equal amount of random input if insufficient input is available. Reads from the **/dev/urandom** device always return the quantity of output requested without blocking. If insufficient random input is available, alternate input will be processed by the random number generator to provide cryptographically secure output, the strength of which will reflect the strength of the algorithms used by the random number generator. Output generated without random input is theoretically less secure than output generated from random input, so **/dev/random** should be used for applications for which a high level of confidence in the security of the output is required.

Data written to either device is added to the pool of stored random input and may be used for generating output. Writes behave identically for both devices and will not block.

### **Implementation Specifics**

The **/dev/random** and **/dev/urandom** devices are created from major and minor numbers assigned by the device configuration subsystem when the random number generator is loaded, so the device names should always be used when attempting to locate or open the devices. The devices are deleted when the random number generator is unloaded. When the system is shut down using the shutdown command, output is taken from the **/dev/urandom** device and is written back to the **/dev/random** device when the random number generator is loaded on the next boot to provide starting entropy to the generator, enhancing the quality of the stored random input after boot.

Input is gathered from interrupt timings when the pool of stored random input falls below half full and continues to be gathered until the pool is again full. This process causes a minor performance impact to all external interrupts while timings are being gathered, which ceases when timings cease to be gathered. Data written to either of the random devices will also contribute to the pool of stored random input and can influence the output, thus writing to these devices should be a privileged operation. This is enforced

by the permissions of the devices, so it can be changed by the administrator to be completely disallowed if desired.

## **usb0 Special File**

### **Purpose**

Provides access to the Universal Serial Bus (USB) protocol driver.

### **Syntax**

```
#include <sys/dump.h>
```

### **Description**

The **usb0** special file provides an interface to a USB protocol pseudo device. This special file must not be opened directly by application programs (with the exception of diagnostics applications). The **usb0** special file is only special file created as USB protocol pseudo device irrespective of the type of the host controllers.

The description of the USBD Protocol Device Driver in the *AIX® Version 7.1 Technical Reference: Kernel and Subsystems, Volume 1* provides the implementation specification for the USB Protocol driver.

## **usbhc Special File**

### **Purpose**

Provides access to the Universal Serial Bus (USB) adapter device driver. This host controller adapter device can be: a Enhanced Host Controller Interface (EHCI) or Extensible Host Controller Interface (xHCI) or Open Host Controller Interface (OHCI).

### **Description**

The **usbhc** special file provides an interface to an USB adapter device. This special file must not be opened directly by the application programs (with the exception of diagnostics applications). The **/dev/usbhc0..** and **/dev/usbhc1..** are the special files.

For each physical EHCI capable adapter, three special files will be created out of which two provide interface to the OHCI (companion controllers) and the other provides interface to the EHCI controller. For each physical OHCI and XHCI capable adapters, one special file will be created.

## **usbms Special File**

### **Purpose**

Provides access to the Universal Serial Bus (USB) Mass Storage Client device driver.

### **Description**

The **usbms** special file provides block and character (raw) access to USB Bulk Mass Storage devices similar to Removable Disk EXchange (RDX), flash drives, and disk devices.

The **r** prefix on a special file name means that the drive is accessed as a raw device rather than a block device. The performance of all data transfers in multiples of the logical block length of the disk is required for performing raw I/O operation on a RDX, flash drive, and disk drive devices. Also, all the **lseek** subroutines made to the raw USB Mass storage device must set the file offset pointer to a value that is a multiple of the specified logical block size.

## **USB Mass Storage Bulk Flash or RDX Devices**

The special files `/dev/usbms0` and `/dev/usbms1`,... provide block access to USB Mass Storage Bulk Flash or RDX devices. The special file `/dev/rusbms0`, `/dev/rusbms1`,... provide character access.

When a RDX cartridge is ejected from the drive for a mounted CD-ROM or UDFS file system, the files on the cartridge cannot be accessed. Before these files can be accessed again, the file systems mounted from the cartridge must be unmounted. Processes that have open files on these file systems must be exited. Processes that have current directories on these file systems must be moved. If these actions do not work, perform a force unmount.

The **man** command can become unresponsive if you eject the RDX cartridge from a mounted CD-ROM or UDFS file system. Reinserting the cartridge disc does not fix the problem. All processes (graphical and ASCII) must be exited and the file system must be force unmounted and mounted again. The **man** commands can then be started again.

The description of the USB mass storage client device driver in the *AIX® Version 7.1 Technical Reference: Kernel and Subsystems, Volume 1* provides the implementation specifications for the USB Mass Storage Client Device Driver.

## **vty\_server Special File**

### **Purpose**

The virtual terminal server (vty\_server or vts) is an AIX device driver used to create a tty-style connection from the partition on which the virtual terminal server is running to a virtual terminal (not a virtual terminal server) on another partition.

### **Description**

The vty has a master side (vty server) and a slave side (vty). The vty server is opened and used by special programs such as **mkvterm**. The vty is opened and used by shells such as **ksh**. The data path is bidirectional.

#### **vts\_ioctl**

The **vts\_ioctl** command is called via the device switch table when an application calls ioctl with a file descriptor that was returned from a successful open of a vts port. vts\_ioctl performs specialized control operations on the port.

#### **Syntax**

```
struct vts_ioctl {
 void *vi_buffer; /* pointer to user's buffer */
 int vi_bufsize; /* size of user's buffer */
 int vi_offset; /* offset into data */
 int vi_result; /* bytes transferred */
};
```

The **vi\_buffer** parameter is a pointer to a buffer in user space. The **vi\_bufsize** parameter specifies the size of the buffer. For VTS\_READ\_CLCS and VTS\_READ\_PARTNER, data is moved from the vts driver into the buffer specified by **vi\_buffer**. For VTS\_WRITE\_PARTNER, data is pulled from the buffer specified by **vi\_buffer** and moved into the vts driver.

The **vi\_offset** parameter is used only for VTS\_READ\_CLCS. An application can make multiple VTS\_READ\_CLCS ioctl calls; the driver may have more data to transfer to the application than will fit in the buffer that is specified by the **vi\_buffer** parameter.

The **vi\_offset** is set to 0 for the first VTS\_READ\_CLCS. This causes the driver to query PHYP for the current list of possible CLCs. The first sequence of the CLCs is moved into user space. Each CLC is separated by a new line and the last CLC is terminated by a null. A count of the number of bytes moved into user space (excluding the terminating null) is stored in **vi\_result**.

The application determines how the data is processed (for example, the application may save the data in a linked list). **vi\_result** is then added to **vi\_offset** and another VTS\_READ\_CLCS is performed. This causes the driver to move the next set of CLCs into the application's buffer. This sequence of operations continues until zero is returned in **vi\_result**.

A sequence of VTS\_READ\_CLCS calls results in a sequence of CLCs separated by new lines and terminated by a null. The following are the possible error conditions:

**EIO** A driver call to PHYP returned with an error.

**ENOMEM**

No memory is available to hold the CLC list.

**EPERM**

The copyin or copyout failed.

A VTS\_WRITE\_PARTNER call returns the value that was passed on the last successful VTS\_WRITE\_PARTNER call. If the vts is not currently connected, a null string is returned. The only possible errors are errors that are returned by copyin or copyout routines.

The VTS\_WRITE\_PARTNER call creates and ends connections. The following are possible errors when ending a connection:

**ENXIO**

The vts is not currently connected.

**EIO** The H\_FREE\_VTERM call to PHYP returned H\_HARDWARE. This usually indicates that there is a problem with PHYP or that the partition connection failed.

**EINVAL**

The H\_FREE\_VTERM call to PHYP returned H\_PARAMETER. This usually indicates a driver problem.

To create a connection, the buffer must contain a CLC that was passed from VTS\_READ\_CLCS. The CLC can contain the ending new line, which is removed. The following are possible errors:

**EBUSY**

The vts is already connected. Use VTS\_READ\_PARTNER to determine where the vts is connected, or use VTS\_WRITE\_PARTNER with a null name to end the connection.

**EINVAL**

The CLC that was passed is not in the list of valid connections for this vts. EINVAL is also returned if the H\_REGISTER\_VTERM call to PHYP returns H\_PARAMETER.

**Note:** If a reconfiguration has occurred, the list of valid CLCs may have changed.

**EIO** The H\_REGISTER\_VTERM call to PHYP returned H\_PARAMETER. This may be due to a failed PHYP.

## **x25sn Special File**

### **Purpose**

Provides access to the X.25 Interface Co-Processor/2 adapters by way of the X.25 Interface Co-Processor/2 device handler.

### **Description**

The **x25sn** character special file provides access to the X.25 Interface Co-Processor/2 device handler, which provides access to a X.25 packet switching network. The device handler supports up to four X.25 Interface Co-Processor/2 adapters.

### **Usage Considerations**

When accessing the X.25 Interface Co-Processor/2 device handler, the following should be taken into account:

| Item                                         | Description                                                                                                                             |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Driver initialization and termination</b> | The device handler may be loaded and unloaded. The device handler supports the configuration calls to initialize and terminate itself.  |
| <b>Special file support</b>                  | Calls other than the <b>open</b> and <b>close</b> subroutines are discussed based on the mode in which the device handler is operating. |

### **Subroutine Support**

The X.25 Interface Co-Processor/2 device handler provides specific support for the **open**, **close**, **read**, **write**, and **ioctl** subroutines.

#### **open and close Subroutines**

The device handler supports the **/dev/x25sn** special file as a character-multiplex special file. The special file must be opened for both reading and writing (**O\_RDWR**). There are no particular considerations for closing the special file. The special file name used in an **open** call differs depending upon how the device is to be opened. For each of the following types of special files, the value *n* is  $0 \leq n \leq 7$ :

| Item                | Description                                                                                                           |
|---------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>/dev/x25sn</b>   | Starts the device handler on the next available port.                                                                 |
| <b>/dev/x25sn/D</b> | Opens the device handler for the specified port in Diagnostic mode.                                                   |
| <b>/dev/x25sn/M</b> | Opens the device handler for reading and writing data to the monitor facilities on the X.25 Interface Co-Processor/2. |
| <b>/dev/x25sn/R</b> | Opens the device handler for updating the routing table.                                                              |

#### **read Subroutine**

Can take the form of a **read**, **readx**, **readv**, or **readvx** subroutine. For this call, the device handler copies the data into the buffer specified by the caller.

#### **write Subroutine**

Can take the form of a **write**, **writex**, **writev**, or **writevx** subroutine. For this call, the device handler copies the user data into a kernel buffer and transmits the data on the network.

#### **ioctl Subroutine**

The device handler supports the following ioctl operations:

| Item                       | Description                                                               |
|----------------------------|---------------------------------------------------------------------------|
| CIO_DNLD                   | Downloads a task.                                                         |
| CIO_GET_STAT               | Gets device statistics.                                                   |
| CIO_HALT                   | Halts a session.                                                          |
| CIO_QUERY                  | Queries a device.                                                         |
| CIO_START                  | Starts a session.                                                         |
| IOCINFO                    | Identifies a device.                                                      |
| X25_ADD_ROUTER_ID          | Adds a router ID.                                                         |
| X25_COUNTER_GET            | Gets a counter.                                                           |
| X25_COUNTER_READ           | Reads the contents of a counter.                                          |
| X25_COUNTER_REMOVE         | Removes a counter from the system.                                        |
| X25_COUNTER_WAIT           | Waits for the contents of counters to change.                             |
| X25_DELETE_ROUTER_ID       | Deletes a router ID.                                                      |
| X25_DIAG_IO_READ           | Reads to an I/O register on the X.25 Interface Co-Processor/2.            |
| X25_DIAG_IO_WRITE          | Writes to an I/O register on the X.25 Interface Co-Processor/2.           |
| X25_DIAG_MEM_READ          | Reads memory from the X.25 Interface Co-Processor/2 into a user's buffer. |
| X25_DIAG_MEM_WRITE         | Writes memory to the X.25 Interface Co-Processor/2 from a user's buffer.  |
| X25_DIAG_TASK              | Provides the means to download the diagnostics task on to the card.       |
| X25_LINK_CONNECT           | Connects a link.                                                          |
| X25_LINK_DISCONNECT        | Disconnects a link.                                                       |
| X25_LINK_STATUS            | Returns the status of the link.                                           |
| <b>X25_LOCAL_BUSY</b>      | Enables or disables receiving of data packets on a port.                  |
| <b>X25_REJECT</b>          | Rejects a call.                                                           |
| <b>X25_QUERY_ROUTER_ID</b> | Queries a router ID.                                                      |
| <b>X25_QUERY_SESSION</b>   | Queries a session.                                                        |

## Error Conditions

The following error conditions may be returned when accessing the device handler through the `/dev/x25sn` special file:

| Item     | Description                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| EACCES   | Indicates that the call application does not have the required authority.                                                                   |
| EAGAIN   | Indicates there were no packets to be read or the transmit queue is full, and the device was opened with the <code>DNDELAY</code> flag set. |
| EBUSY    | Indicates that the device was busy and could not accept the operation.                                                                      |
| EFAULT   | Indicates that an invalid address was specified.                                                                                            |
| EIDRM    | Indicates that the counter has been removed.                                                                                                |
| EINTR    | Indicates that the subroutine call was interrupted.                                                                                         |
| EINVAL   | Indicates that an invalid parameter was passed to one of the subroutine calls.                                                              |
| EIO      | Indicates that an error has occurred. The status field in the status-control block contains more information.                               |
| EMSGSIZE | Indicates that the data to be given to the user was greater than the length of the buffer specified. The data in the buffer is truncated.   |
| ENOBUFS  | Indicates that no buffers are available.                                                                                                    |
| ENODEV   | Indicates that the device requested does not exist.                                                                                         |
| ENOMEM   | Indicates that the X.25 device handler was unable to allocate space required for the open.                                                  |
| ENOSPC   | Indicates that there are no counters available to allocate.                                                                                 |
| ENXIO    | Indicates that the device was not completely configured. Initial configuration must be completed before any starts can be issued.           |
| EPERM    | Indicates the user does not have permission to perform the requested operation.                                                             |

## Header Files

Information that is needed by several different files or functions is collected into a header file. A header file contains C-language definitions and structures. Centralizing information into a header file facilitates the creation and update of programs. Because **#include** statements are used to insert header files into a C-language program, header files are often referred to as include files.

Header files define the following functions:

- Structures of certain files and subroutines
- Type definition (typedef) synonyms for data types
- System parameters or implementation characteristics
- Constants and macros that are substituted during the C language preprocessing phase

By convention, the names of header files end with **.h** (dot h). The **.h** suffix is used by header files that are provided with the operating system; however, the suffix is not required for user-generated header files.

**Note:** Several of the header files provided with the operating system end with **.inc** (include file).

Additional header files are provided with the operating system. Most of these can be found in either the **/usr/include** directory or the **/usr/include/sys** directory. Use the **pg** command to view the contents of a header file.

More information about the following header files is provided in this documentation:

| Item                 | Description                                                                                                                         |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>a.out.h</b>       | Defines the structure of the standard <b>a.out</b> file.                                                                            |
| <b>acct.h</b>        | Describes the format of the records in the system accounting files.                                                                 |
| <b>ar.h</b>          | Describes the format of an archive file.                                                                                            |
| <b>audit.h</b>       | Defines values used by the auditing system as well as the structure of a bin.                                                       |
| <b>core.h</b>        | Describes the structures created as a result of a core dump.                                                                        |
| <b>ct_ffdc.h</b>     | Provides data types, definitions, and interface prototypes for the First Failure Data Capture (FFDC) C language library interfaces. |
| <b>dirent.h</b>      | Describes the format of a file system-independent directory entry.                                                                  |
| <b>euciocctl.h</b>   | Defines ioctl operations and data types for handling EUC code sets.                                                                 |
| <b>fcntl.h</b>       | Defines values for the <b>fcntl</b> and <b>open</b> subroutines.                                                                    |
| <b>filsys.h</b>      | Contains the format of a file system logical volume.                                                                                |
| <b>flock.h</b>       | Defines the file control options.                                                                                                   |
| <b>fullstat.h</b>    | Describes the data structure returned by the <b>fullstat</b> and <b>ffullstat</b> subroutines.                                      |
| <b>iconv.h</b>       | Defines types, macros, and subroutines for character code set conversion.                                                           |
| <b>ipc.h</b>         | Defines structures used by the subroutines that perform interprocess communications operations.                                     |
| <b>ldr.h</b>         | Describes the <b>ld_info</b> data type and loader entry points.                                                                     |
| <b>libperfstat.h</b> | Describes the structures and constants used by the <b>libperfstat.h</b> API subroutines.                                            |
| <b>limits.h</b>      | Defines implementation limits identified by the IEEE POSIX 1003 standard.                                                           |
| <b>math.h</b>        | Defines math subroutines and constants                                                                                              |
| <b>mode.h</b>        | Defines the interpretation of a file mode.                                                                                          |
| <b>msg.h</b>         | Defines structures used by the subroutines that perform message queueing operations.                                                |
| <b>mtio.h</b>        | Defines the magnetic tape user include file.                                                                                        |
| <b>param.h</b>       | Defines certain hardware-dependent parameters.                                                                                      |
| <b>poll.h</b>        | Defines the <b>pollfd</b> structure used by the <b>poll</b> subroutine.                                                             |
| <b>sem.h</b>         | Defines the structures that are used by subroutines that perform semaphore operations.                                              |
| <b>sgtty.h</b>       | Defines structures used by the Berkeley terminal interface.                                                                         |
| <b>shm.h</b>         | Defines structures used by the subroutines that perform shared memory operations.                                                   |

| Item        | Description                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------|
| spc.h       | Defines external interfaces provided by the System Resource Controller (SRC) subroutines.                                     |
| srcobj.h    | Defines structures used by the System Resource Controller (SRC) subsystem.                                                    |
| stat.h      | Describes the data structure returned by the status subroutines.                                                              |
| statfs.h    | Describes the structure of the statistics returned by the status subroutines.                                                 |
| statvfs.h   | Describes the structure of the statistics that are returned by the <b>statvfs</b> subroutines and <b>fsatvfs</b> subroutines. |
| systemcfg.h | Defines the <b>_system_configuration</b> structure.                                                                           |
| tar.h       | Defines flags used in the <b>tar</b> archive header.                                                                          |
| termio.h    | Defines structures used by the terminal interface for compatibility of Version 2 of the operating system.                     |
| termios.h   | Defines structures used by the POSIX terminal interface.                                                                      |
| termiox.h   | Defines the structure of the <b>termiox</b> file, which provides the extended terminal interface.                             |
| trace.h     | Defines implementation trace identified by IEEE POSIX 1003.                                                                   |
| types.h     | Defines primitive system data types.                                                                                          |
| unistd.h    | Defines POSIX implementation characteristics.                                                                                 |
| utmp.h      | Defines the format of certain user and accounting information files.                                                          |
| values.h    | Defines hardware-dependent values.                                                                                            |
| vmount.h    | Describes the structure of a mounted file system.                                                                             |
| x25sdefs.h  | Contains the structures used by the X.25 application programming interface.                                                   |

## List of Major Control Block Header Files

The Base Operating System constants and control block structure definitions are contained in header files in the **/usr/include** and **/usr/include/sys** directories. The following are the major constants and control blocks and their corresponding header files:

| Item                                 | Description                                                          |
|--------------------------------------|----------------------------------------------------------------------|
| <b>/usr/include/a.out.h</b>          | Common Object File Format (COFF) structures                          |
| <b>/usr/include/core.h</b>           | An include file for the <b>/usr/include/sys/core.h</b> header file   |
| <b>/usr/include/errno.h</b>          | An include file for the <b>/usr/include/sys/errno.h</b> header file  |
| <b>/usr/include/lvmmrec.h</b>        | LVM record structure                                                 |
| <b>/usr/include/sgett.h</b>          | Line discipline structures and constants for Berkeley compatibility  |
| <b>/usr/include/signal.h</b>         | An include file for the <b>/usr/include/sys/signal.h</b> header file |
| <b>/usr/include/termio.h</b>         | An include file for the <b>/usr/include/sys/termio.h</b> header file |
| <b>/usr/include/termios.h</b>        | POSIX line-discipline structures and constants                       |
| <b>/usr/include/xcoff.h</b>          | Extended Common Object File Format structures                        |
| <b>/usr/include/sys/acct.h</b>       | Accounting structures                                                |
| <b>/usr/include/sys/badisk.h</b>     | Bus-attached-disk structures                                         |
| <b>/usr/include/sys/bbdir.h</b>      | Bad-block directory structure                                        |
| <b>/usr/include/sys/bootrecord.h</b> | Boot record structure                                                |
| <b>/usr/include/sys/buf.h</b>        | Buffer header structures                                             |
| <b>/usr/include/sys/cdrom.h</b>      | CD-ROM structures                                                    |
| <b>/usr/include/sys/cfgodm.h</b>     | Configuration object class structures                                |
| <b>/usr/include/sys/configrec.h</b>  | Disk configuration record structure                                  |
| <b>/usr/include/sys/core.h</b>       | Core dump structure                                                  |
| <b>/usr/include/sys/debug.h</b>      | Traceback table or procedure-end table                               |
| <b>/usr/include/sys/device.h</b>     | Device switch table                                                  |
| <b>/usr/include/sys/deviceq.h</b>    | Device queue-management structures                                   |
| <b>/usr/include/sys/devinfo.h</b>    | Device information structures                                        |
| <b>/usr/include/sys/dir.h</b>        | Directory entry structures                                           |
| <b>/usr/include/sys/display.h</b>    | Virtual display driver structures                                    |
| <b>/usr/include/sys/dump.h</b>       | Component dump table structure                                       |
| <b>/usr/include/sys/entuser.h</b>    | Ethernet device driver structures                                    |
| <b>/usr/include/sys/errids.h</b>     | Error-log record identifiers                                         |
| <b>/usr/include/sys/errno.h</b>      | Error codes                                                          |
| <b>/usr/include/sys/fd.h</b>         | Diskette device driver structures                                    |
| <b>/usr/include/sys/file.h</b>       | File structure                                                       |

| Item                                      | Description                                                                                     |
|-------------------------------------------|-------------------------------------------------------------------------------------------------|
| <code>/usr/include/sys/fstypes.h</code>   | File-system parameter table                                                                     |
| <code>/usr/include/sys/hd_psn.h</code>    | Layout of reserved space on the disk                                                            |
| <code>/usr/include/sys/ide.h</code>       | IDE device driver structures                                                                    |
| <code>/usr/include/sys/inode.h</code>     | I-node structures                                                                               |
| <code>/usr/include/sys/intr.h</code>      | Interrupt handler structures                                                                    |
| <code>/usr/include/sys/ipc.h</code>       | Interprocess Communications (IPC) structures                                                    |
| Item                                      | Description                                                                                     |
| <code>/usr/include/sys/iplcb.h</code>     | Initial Program Load (IPL) control block structure                                              |
| <code>/usr/include/sys/ldr.h</code>       | Loader structures and constants                                                                 |
| <code>/usr/include/sys/low.h</code>       | Kernel Page 0 definition                                                                        |
| <code>/usr/include/sys/machine.h</code>   | Machine dependent control registers                                                             |
| <code>/usr/include/sys/mbuf.h</code>      | Memory buffer structures                                                                        |
| <code>/usr/include/sys/mdio.h</code>      | Machine device driver structures                                                                |
| <code>/usr/include/sys/mount.h</code>     | Mount structures                                                                                |
| <code>/usr/include/sys/mpqp.h</code>      | Multiprotocol Quad Port (MPQP) device-driver structures                                         |
| <code>/usr/include/sys/msg.h</code>       | Message queue structures                                                                        |
| <code>/usr/include/sys/mstsave.h</code>   | Machine State Save Area structures                                                              |
| <code>/usr/include/sys/param.h</code>     | Process management constants                                                                    |
| <code>/usr/include/sys/pri.h</code>       | Constants for process priorities                                                                |
| <code>/usr/include/sys/proc.h</code>      | Process table structure                                                                         |
| <code>/usr/include/sys/pseg.h</code>      | Process private segment layout                                                                  |
| <code>/usr/include/sys/reg.h</code>       | Machine-dependent registers                                                                     |
| <code>/usr/include/sys/scdisk.h</code>    | SCSI-disk device driver structures                                                              |
| <code>/usr/include/sys/scsi.h</code>      | SCSI device driver structures                                                                   |
| <code>/usr/include/sys/seg.h</code>       | Memory management constants                                                                     |
| <code>/usr/include/sys/sem.h</code>       | Semaphore structures                                                                            |
| <code>/usr/include/sys/shm.h</code>       | Shared-memory facility structures                                                               |
| <code>/usr/include/sys/signal.h</code>    | Signal structures and constants                                                                 |
| <code>/usr/include/sys/socketvar.h</code> | Sockets structures                                                                              |
| <code>/usr/include/sys/stat.h</code>      | File status structure                                                                           |

| <code>/usr/include/sys/xmem.h</code>      | Cross memory service structures                                                                 |

## ct\_ffdc.h File

### Purpose

Provides data types, definitions, and interface prototypes for the First Failure Data Capture (FFDC) C language library interfaces.

### Description

This header file must be included by any C and C++ language source code files that make use of the First Failure Data Capture C language interfaces. This file contains the C language prototypes for the First

Failure Data Capture interfaces, the symbolic constants used as return codes from these interfaces, and data type definitions needed by First Failure Data Capture C and C++ language clients.

## C Language Interface Selection Control

This file provides the compiler definition **FC\_VERSION**. This definition controls which version of the First Failure Data Capture interfaces should be used during compilation of the source code. Currently, only one version of the First Failure Data Capture interfaces are available, and the value of **FC\_VERSION** is set to a default value of 1. Future versions of the First Failure Data Capture interfaces can be used during compilation—when they become available—by setting the value for **FC\_VERSION** on the compilation command line. If this variable is not set during compilation, the value for **FC\_VERSION** reverts to the default value of 1, and the initial version of the FFDC interfaces is used.

## Data Types

The **fc\_eid\_t** data type defined by this module is used to store a First Failure Data Capture Failure Identifier. This identifier is created by the **fc\_push\_stack** and **fc\_log\_error** interfaces whenever these interfaces are successful in recording failure information. This identifier contains information in an encoded form to indicate the system on which the record was made, the time when the record was made, and the location of the record. First Failure Data Capture commands such as **fcreport** and **fcstkrpt** can be used at a later time to obtain the exact failure report for problem determination efforts.

## FFDC Environment Establishment Codes

A First Failure Data Capture client application uses the **fc\_init** interface to specify how the FFDC Environment should be established. The following selections are supported:

### **FC\_LOG**

A basic FFDC Environment is established, which permits the application to record failure information to the AIX Error Log and the BSD System Log. An FFDC Error Stack is not established for use by the application in this case, unless this value is combined with either the **FC\_STACK\_CREAT** or the **FC\_STACK\_INHERIT** options described below. This selection would be used by applications making use of the **fc\_log\_error** interface only.

### **FC\_STACK\_CREAT**

Creates an FFDC Error Stack Environment if one was not previously created by an ancestor of this process, or inherits the FFDC Error Stack Environment if an ancestor previously established one. The FFDC Error Stack Environment permits the application to record information to the AIX Error Log, the BSD System Log, and the FFDC Error Stack. This selection is used by applications that wish to use the **fc\_push\_stack** interface as well as the **fc\_log\_error** interface. This selection is not to be combined with the **FC\_STACK\_INHERIT** option described next.

### **FC\_STACK\_INHERIT**

Inherit an FFDC Error Stack Environment only if an ancestor process previously established an FFDC Error Stack Environment. If an ancestor did not establish such an environment, the application does not make use of an FFDC Error Stack, but may still make use of the AIX Error Log and the BSD System Log. Do not combine this selection with the **FC\_STACK\_CREAT** option specified previously.

## Record Type Definitions

Seven FFDC Event Types are specified in this file. These event types are used to instruct the **fc\_log\_error** interface as to the severity of the condition being logged:

### **FFDC\_EMERG**

A severe failure has occurred, and the system is in danger of coming offline. This information is required by the system administrator to bring the system back online. The AIX Error Log type equivalent is PEND. The BSD System Log priority equivalent is **LOG\_EMERG**.

#### **FFDC\_ERROR**

A permanent failure has occurred, and the condition will persist until it is repaired. The system is not in danger of coming offline. The AIX Error Log type equivalent is PERM. The BSD System Log priority equivalent is **LOG\_ERR**.

#### **FFDC\_STATE**

An event of some significance has occurred, but the event does not constitute a failure condition. The AIX Error Log type equivalent is INFO. The BSD System Log priority equivalent is **LOG\_NOTICE**.

#### **FFDC\_PERF**

A condition has been noticed which can or will degrade the system's performance below acceptable levels. The system is not in danger of coming offline, but performance may be unacceptably slow, which can result in random failures in system applications, such as timeout conditions. The AIX Error Log type equivalent is PERF. The BSD System Log priority equivalent is **LOG\_WARNING**.

#### **FFDC\_TRACE**

This entry identifies the name and location of a trace file generated by an application or system component. Such an entry would be made when a trace has been enabled in an application or a component, to indicate where the trace file resides. The AIX Error Log type equivalent is UNKN. The BSD System Log priority equivalent is **LOG\_INFO**.

#### **FFDC\_RECOV**

A recovery action has been successfully completed by the system in response to an **FFDC\_EMERG**, **FFDC\_ERROR**, or **FFDC\_PERF** condition. Such an entry would be created only after an **FFDC\_EMERG**, **FFDC\_ERROR**, or **FFDC\_PERF** condition was detected, and a recovery action started in response to that condition completed successfully. The AIX Error Log type equivalent is TEMP. The BSD System Log priority equivalent is **LOG\_DEBUG**.

#### **FFDC\_DEBUG**

A failure condition was detected. Unlike the **FFDC\_ERROR** case, the failure is not a permanent condition, or the system can continue successfully with the condition present. The AIX Error Log type equivalent is UNKN. The BSD System Log priority equivalent is **LOG\_DEBUG**.

### **Examples**

To use this file in a C or C++ language program, add the following line near the beginning of the source code module:

```
#include <rsct/ct_ffcd.h>
```

### **Location**

/opt/rsct/include/ct\_ffdc.h

/usr/include/rsct/ct\_ffdc.h

### **dirent.h File**

The **\_DNAME\_MAX** and **PATH\_MAX** constants specify maximum file names and path names, respectively, across all types of file systems. The constants defined by a particular file system are

applicable only to that file system. Using file system-specific constants and directory structures makes it very difficult to port code across different types of file systems.

## Purpose

Describes the format of a file system-independent directory entry.

## Description

The `/usr/include/dirent.h` file describes the format of a directory entry without reference to the type of underlying system.

The **dirent** structure, defined in the **dirent.h** file, is used for directory access operations. Using these access operations and the **dirent** structure, along with its associated constants and macros, shields you from the details of implementing a directory and provides a consistent interface to directories across all types of file systems.

The **dirent** structure contains the following fields for each directory entry:

```
ulong_t d_offset; /* actual offset of this entry */
ino_t d_ino; /* inode number of entry */
ushort_t d_reclen; /* length of this entry */
ushort_t d_namlen; /* length of string in d_name */
char d_name[_D_NAME_MAX+1]; /* name of entry (filename) */
```

**\_D\_NAME\_MAX** is a constant that indicates the maximum number of bytes in a file name for all file systems. (Related to this constant is the **PATH\_MAX** constant, which specifies the maximum number of bytes in the full path name of a file, not including the terminating null byte.)

The value of the **\_D\_NAME\_MAX** constant is specific to each type of filesystem type. It can be determined by using the **pathconf** or **fpathconf** subroutine.

The size of a **dirent** structure depends on the number of bytes in the file name.

## difcn.h File

## Purpose

Describes dynamic linking.

## Syntax

```
#include <difcn.h>
```

## Description

The `<difcn.h>` header defines at least the following macros for use in the construction of a `dlopen` mode argument:

| Item        | Description                                                                    |
|-------------|--------------------------------------------------------------------------------|
| RTLD_LAZY   | Relocations are performed at an implementation-dependent time.                 |
| RTLD_NOW    | Relocations are performed when the object is loaded.                           |
| RTLD_GLOBAL | All symbols are available for relocation processing of other modules           |
| RTLD_LOCAL  | All symbols are not made available for relocation processing by other modules. |

The header <dlfcn.h> declares the following functions, which may also be defined as macros:

```
void *dlopen(const char *, int);
void *dlsym(void *, const char *);
int dlclose(void *);
char *dlerror(void);
```

## eucioc.h File

### Purpose

Defines ioctl operations and data types for handling EUC code sets.

### Description

The **eucioc.h** file contains information used for handling Extended UNIX Code (EUC) multibyte code sets. It consists of ioctl operations and the related data structure.

The **eucioc** structure contains the following fields:

| Item    | Description                                                                                                                                          |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| eucw[4] | Specifies the memory width of the code set. It indicates the number of bytes used to store the multibyte characters of each of the four classes.     |
| scrw[4] | Specifies the screen width of the code set. It indicates the number of columns used to display the multibyte characters of each of the four classes. |

This structure is used in the following ioctl operations:

| Item     | Description                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------|
| EUC_WGET | Returns the EUC character widths. The <b>eucioc</b> structure is filled with the memory and screen widths of the current EUC code set. |
| EUC_WSET | Sets the EUC character widths. The <b>eucioc</b> structure is used to set the memory and screen widths of the current EUC code set.    |

## fcntl.h File

### Purpose

Defines file control options.

## Description

The `/usr/include/fcntl.h` file defines the values that can be specified for the *Command* and *Argument* parameters of the `fcntl` subroutine and for the *Oflag* parameter of the `open` subroutine. The file-status flags of an open file are described in the following information.

### Flag Values for open Subroutine

The following flag values are accessible only to the `open` subroutine:

| Item                  | Description                                                                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>O_RDONLY</code> | Read-only                                                                                                                                                                                                     |
| <code>O_WRONLY</code> | Write-only                                                                                                                                                                                                    |
| <code>O_RDWR</code>   | Read and write                                                                                                                                                                                                |
| <code>O_CREAT</code>  | Open with file create (uses the third <code>open</code> argument)                                                                                                                                             |
| <code>O_TRUNC</code>  | Open with truncation                                                                                                                                                                                          |
| <code>O_DIRECT</code> | Open for Direct I/O                                                                                                                                                                                           |
| <code>O_EXCL</code>   | Exclusive open<br><b>Note:</b> The <code>O_EXCL</code> flag is not fully supported for Network File Systems (NFS). The NFS protocol does not guarantee the designed function of the <code>O_EXCL</code> flag. |
| <code>O_NOCTTY</code> | Do not assign a controlling terminal                                                                                                                                                                          |
| <code>O_RSHARE</code> | Read shared open                                                                                                                                                                                              |
| <code>O_NSHARE</code> | Read shared open                                                                                                                                                                                              |

### File Access Mode Mask

The `O_ACCMODE` mask is used to determine the file access mode.

### File Status Flags for open and fcntl Subroutines

The following file status flags are accessible to both the `open` and `fcntl` subroutines:

| Item                     | Description                                 |
|--------------------------|---------------------------------------------|
| <code>O_NONBLOCK</code>  | POSIX nonblocking I/O                       |
| <code>FNONBLOCK</code>   | POSIX nonblocking I/O                       |
| <code>O_APPEND</code>    | An append with writes guaranteed at the end |
| <code>FAPPEND</code>     | An append with writes guaranteed at the end |
| <code>O_SYNC</code>      | Synchronous write option                    |
| <code>FSYNC</code>       | Synchronous write option                    |
| <code>O_DSYNC</code>     | Synchronous write option (file data only).  |
| <code>FDATASYNC</code>   | Synchronous write option (file data only).  |
| <code>O_RSYNC</code>     | Synchronous file attributes on read.        |
| <code>FREADSYNC</code>   | Synchronous file attributes on read.        |
| <code>FASYNC</code>      | Asynchronous I/O                            |
| <code>O_NDELAY</code>    | Nonblocking I/O                             |
| <code>FNDELAY</code>     | Nonblocking I/O                             |
| <code>O_LARGEFILE</code> | Access to large files enabled .             |

### File Status Flags for open Subroutine

The following file status flags are accessible to the `open` subroutine:

| Item     | Description         |
|----------|---------------------|
| O_DEFER  | Deferred update     |
| O_DELAY  | Open with delay     |
| O_DIRECT | Open for Direct I/O |

### File Descriptor Flags for **fcntl** Subroutine

The following file descriptor flag is accessible to the **fcntl** subroutine:

| Item       | Description                     |
|------------|---------------------------------|
| FD_CLOEXEC | Close this file during an exec. |

File flag values corresponding to file access modes are as follows:

| Item   | Description             |
|--------|-------------------------|
| FREAD  | File is open for read.  |
| FWRITE | File is open for write. |

#### Note:

1. The **FREAD** and **FWRITE** flags cannot be used unless the **\_KERNEL** flag has been defined.
2. The **ldfcn.h** file also assigns values to the **FREAD** and **FWRITE** options. If you use the **ldfcn.h** and **fcntl.h** files together, directly or indirectly, you should use the **#undef** statement on the **FREAD** and **FWRITE** options of one of the header files. If you do not, the compiler will return a warning about using duplicate definitions.

### Command Values for **fcntl** Subroutine

The *Command* values for the **fcntl** subroutine (that is, for **fcntl** subroutine requests) are:

| Item       | Description                                      |
|------------|--------------------------------------------------|
| F_DUPFD    | Duplicate the file description.                  |
| F_GETFD    | Get the file description flags.                  |
| F_SETFD    | Set the file description flags.                  |
| F_GETFL    | Get the file status flags and file access modes. |
| F_SETFL    | Set the file flags.                              |
| F_GETLK    | Return information about an existing file lock.  |
| F_GETLK64  | Return information about an existing file lock.  |
| F_SETLK    | Set or clear a file lock.                        |
| F_SETLK64  | Set or clear a file lock.                        |
| F_SETLKW   | Set or clear a file lock and wait if blocked.    |
| F_SETLKW64 | Set or clear a file lock and wait if blocked.    |
| F_GETOWN   | Get the descriptor owner.                        |
| F_SETOWN   | Set the descriptor owner.                        |

### Socket Restrictions

The following *Command* values return **EINVAL** for sockets:

- **F\_SETLK**
- **F\_SETLKW**
- **F\_SETLK64**

## filsys.h File

### Purpose

Contains the format of a Journaled File System (JFS) logical volume.

### Syntax

```
#include <sys/filsys.h>
```

### Description

The **filsys.h** file contains the format of a JFS file system. A JFS file system has a common format for vital information and is divided into a number of fixed-sized units, or fragments. Fragments serve as the basic unit of file system disk space allocation and can be smaller than the file system logical block size, which is 4096 bytes. The file system superblock records the logical block size and fragment size, as well as the size of the entire file system.

A unique feature of the JFS is the implementation of file system metadata as unnamed files that reside in that file system. For example, the disk i-nodes for any file system are contained in the blocks fragments allocated to the file described by the **INODES\_I** i-node. The i-node number for the boot file is 0. Each of the following reserved i-nodes corresponds to a file system metadata file:

| Item               | Description                             |
|--------------------|-----------------------------------------|
| <b>SUPER_I</b>     | Superblock file                         |
| <b>INODES_I</b>    | Disk i-nodes                            |
| <b>INDIR_I</b>     | Indirect file blocks, double and single |
| <b>INOMAP_I</b>    | i-node allocation bit map               |
| <b>ROOTDIR_I</b>   | Root directory i-node                   |
| <b>DISKMAP_I</b>   | Block Fragment allocation bit map       |
| <b>INODEX_I</b>    | i-node extensions                       |
| <b>INODEXMAP_I</b> | Allocation map for i-node extensions    |

The first 4096 bytes of the file system are unused and available to contain a bootstrap program or other information. The second 4096 bytes of the file system are used to hold the file system superblock. The structure of a JFS superblock follows:

```
/* The following disk-blocks are formatted or reserved:
 *
 * ipl block 0 - not changed by filesystem.
 *
 * superblocks at 1 x 4096 (primary superblock) and 31 x
 * 4096 (secondary superblock). the secondary super-block
 * location is likely to be on a different disk-surface than
 * the primary super-block. both structures are allocated as
 * fragments in ".superblock".
 *
 * fragments for .inodes according to BSD layout. each
 * allocation group contains a fixed number of disk inodes.
 * for fsv3 file systems, each allocation group contains one
 * inode per 4096 byte fragment of the allocation group,
```

```

* with the number of fragments within each group described
* by the s_agsize field of the superblock. for fsv3p file
* systems, the number of inodes per group is described by
* the s_iagsize field of the superblock and may be less
* than or greater than the number of fragments per group.
* for these file systems, s_agsize describes the number of
* s fragsize fragments contained within each allocation
* group.
*
* the first allocation group inodes starts at 32 x
* 4096 bytes and consumes consecutive fragments sufficient
* to hold the group's inodes. the inode fragments for all
* other allocation groups start in the first fragments of
* the allocation group and continue in consecutive
* fragments sufficient to hold the group's inodes.
*
* other fragments are allocated for .indirect, .diskmap,
* .inodemap, and their indirect blocks starting in the
* first allocation-group.
*
* The special fs inodes formatted and their usage is as follows:
*
* inode 0 - never allocated - reserved by setting
* n_link = 1
* inode 1 - inode for .superblock
* inode 2 - inode for root directory
* inode 3 - inode for .inodes
* inode 4 - inode for .indirect
* inode 5 - inode for .inodemap - allocation map for
* .inodes
* inode 6 - inode for .diskmap - disk allocation map
* inode 7 - inode for .inode - inode extensions
* inode 8 - inode for .inode - allocation map for
* .inode
* inode 9 - 16 - reserved for future extensions
*
* except for the root directory, the special inodes are not in
* any directory.

#define fsv4pvers 1

```

The path name of this file is `/usr/include/jfs/filsys.h`. But, if the `/usr/include/sys/filsys.h` file is included, the `/usr/include/jfs/filsys.h` file is included by default.

The fields of the superblock structure have the following functions:

| Item        | Description                                                                                                                                                                                                                                                                                                                                                                         |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s_fname     | Specifies the name of the file system.                                                                                                                                                                                                                                                                                                                                              |
| s_fpack     | Specifies the name of the volume on which the file system resides.                                                                                                                                                                                                                                                                                                                  |
| s_fsize     | Specifies the entire file system size in 512-byte units.                                                                                                                                                                                                                                                                                                                            |
| s_bsize     | Specifies the file-system logical block size in bytes.                                                                                                                                                                                                                                                                                                                              |
| s_fragsize  | Specifies the file system fragment size and is only valid for fsv3p file systems. For fsv3 file systems, the file-system fragment size is logically defined as the file-system logical block size.                                                                                                                                                                                  |
| s_iagsize   | Specifies the number of fragments per file system allocation group. For fsv3 file systems, this field also specifies the number of disk i-nodes per file system allocation group.                                                                                                                                                                                                   |
| s_iagsize   | Specifies the number of disk i-nodes per file system allocation group for fsv3p file systems. The s_iagsize field is only valid for fsv3p file systems.                                                                                                                                                                                                                             |
| s_magic     | Specifies the file-system magic number and is used to validate file systems. The <i>magic number</i> is encoded as a 4-byte character string to make it possible to validate the superblock without knowing the byte order of the remaining fields. To check for a valid fsv3 superblock, use a condition similar to:<br><code>if (strncmp(sp-&gt;s_magic,fsv3magic,4) == 0)</code> |
| s_version   | For fsv3p file systems, superblock validation is made by checking both the s_magic and s_version fields.<br>Specifies the file-system version number and is only valid for fsv3p file systems. To check for a valid fsv3p superblock, use a condition similar to:<br><code>if (strncmp(sp-&gt;s_magic,fsv3pmagic,4) == 0 &amp;&amp; sp-&gt;s_version == fsv3pvers)</code>           |
| s_logdev    | Specifies the device ID of the file system log device.                                                                                                                                                                                                                                                                                                                              |
| s_logserial | Records the serial number of the log device at the time the file system was last mounted as modifiable.                                                                                                                                                                                                                                                                             |

| Item       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| s_fmod     | <p>Contains a flag to indicate the cleanliness of the file system. Whenever a file system is mounted, this flag is checked and a warning message is printed if the s_fmod field is equal to nonzero. A file system whose s_fmod field is equal to 0 is very likely to be clean, and a file system whose s_fmod field is equal to 2 is likely to have problems. The s_fmod field is intended to be a three-state flag with the third state being a sticky state. The three states are:</p> <ul style="list-style-type: none"> <li>• 0 = File system is clean and unmounted.</li> <li>• 1 = File system is clean and mounted.</li> <li>• 2 = File system was mounted dirty.</li> </ul> <p>If you only mount and unmount the file system, the flag toggles back and forth between states 0 and 1. If you mount the file system while the flag is in state 1, the flag goes to state 2 and stays there until you run the <b>fsck</b> command. The only way to clean up a corrupted file system (change the flag from state 2 back to state 0) is to run the <b>fsck</b> command.</p> |
| s_readonly | Contains a flag indicating that the file system is mounted read-only. This flag is maintained in memory only; its value on disk is not valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| s_time     | Specifies the last time the superblock of the file system was changed (in seconds since 00:00 Jan. 1, 1970 (GMT)).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## flock.h File

### Purpose

Defines file control options.

### Description

The **flock** structure in the **/usr/include/sys/flock.h** file, which describes a lock, contains the following fields:

| Item   | Description                                                                                                                                                                                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| l_type | Describes the type of lock. If the value of the <i>Command</i> parameter to the <b>fcntl</b> subroutine is <b>F_SETLK</b> or <b>F_SETLKW</b> , the l_type field indicates the type of lock to be created. Possible values are: |

#### **F\_RDLCK**

A read lock is requested.

#### **F\_WRLCK**

A write lock is requested.

#### **F\_UNLCK**

Unlock. An existing lock is to be removed.

If the value of the *Command* parameter to the **fcntl** subroutine is **F\_GETLK**, the l\_type field describes an existing lock. Possible values are:

#### **F\_RDLCK**

A conflicting read lock exists.

#### **F\_WRLCK**

A conflicting write lock exists.

#### **F\_UNLCK**

No conflicting lock exists.

| <b>Item</b>                                                 | <b>Description</b>                                                                                                                                                                                                         |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l_whence</code>                                       | Defines the starting offset. The value of this field indicates the point from which the relative offset, the <code>l_start</code> field, is measured. Possible values are:                                                 |
| <b>SEEK_SET</b>                                             | The relative offset is measured from the start of the file.                                                                                                                                                                |
| <b>SEEK_CUR</b>                                             | The relative offset is measured from the current position.                                                                                                                                                                 |
| <b>SEEK_END</b>                                             | The relative offset is measured from the end of the file.                                                                                                                                                                  |
| These values are defined in the <code>unistd.h</code> file. |                                                                                                                                                                                                                            |
| <code>l_start</code>                                        | Defines the relative offset in bytes, measured from the starting point in the <code>l_whence</code> field.                                                                                                                 |
| <code>l_len</code>                                          | Specifies the number of consecutive bytes to be locked.                                                                                                                                                                    |
| <code>l_sysid</code>                                        | Contains the ID of the node that already has a lock placed on the area defined by the <code>fcntl</code> subroutine. This field is returned only when the value of the <i>Command</i> parameter is <code>F_GETLK</code> .  |
| <code>l_pid</code>                                          | Contains the ID of a process that already has a lock placed on the area defined by the <code>fcntl</code> subroutine. This field is returned only when the value of the <i>Command</i> parameter is <code>F_GETLK</code> . |
| <code>l_vfs</code>                                          | Specifies the file system type of the node identified in the <code>l_sysid</code> field.                                                                                                                                   |

Although the `flock` structure is used by application programs to make file lock requests, the extended `flock` structure, `struct eflock`, is used internally by the kernel. The `eflock` structure is identical to the `flock` structure in that it has the same fields. The differences are that the `l_len` and `l_start` fields are 64 bit integers.

The `flock64` structure in the `/usr/include/sys/flock.h` file, which describes a lock, contains the following fields:

| <b>Item</b>                                                                                                                                                                                | <b>Description</b>                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>l_type</code>                                                                                                                                                                        | Describes the type of lock. If the value of the <i>Command</i> parameter to the <code>fcntl</code> subroutine is <code>F_SETLK</code> or <code>F_SETLKW</code> , the <code>l_type</code> field indicates the type of lock to be created. Possible values are: |
| <b>F_RDLCK</b>                                                                                                                                                                             | A read lock is requested.                                                                                                                                                                                                                                     |
| <b>F_WRLCK</b>                                                                                                                                                                             | A write lock is requested.                                                                                                                                                                                                                                    |
| <b>F_UNLCK</b>                                                                                                                                                                             | Unlock. An existing lock is to be removed.                                                                                                                                                                                                                    |
| If the value of the <i>Command</i> parameter to the <code>fcntl</code> subroutine is <code>F_GETLK</code> , the <code>l_type</code> field describes an existing lock. Possible values are: |                                                                                                                                                                                                                                                               |
| <b>F_RDLCK</b>                                                                                                                                                                             | A conflicting read lock exists.                                                                                                                                                                                                                               |
| <b>F_WRLCK</b>                                                                                                                                                                             | A conflicting write lock exists.                                                                                                                                                                                                                              |
| <b>F_UNLCK</b>                                                                                                                                                                             | No conflicting lock exists.                                                                                                                                                                                                                                   |
| <code>l_whence</code>                                                                                                                                                                      | Defines the starting offset. The value of this field indicates the point from which the relative offset, the <code>l_start</code> field, is measured. Possible values are:                                                                                    |
| <b>SEEK_SET</b>                                                                                                                                                                            | The relative offset is measured from the start of the file.                                                                                                                                                                                                   |
| <b>SEEK_CUR</b>                                                                                                                                                                            | The relative offset is measured from the current position.                                                                                                                                                                                                    |
| <b>SEEK_END</b>                                                                                                                                                                            | The relative offset is measured from the end of the file.                                                                                                                                                                                                     |
| These values are defined in the <code>unistd.h</code> file.                                                                                                                                |                                                                                                                                                                                                                                                               |

| Item    | Description                                                                                                                                                                                     |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| l_start | Defines the relative offset in bytes, measured from the starting point in the l_whence field. This field is of the type off64_t.                                                                |
| l_len   | Specifies the number of consecutive bytes to be locked. This field is of the type off64_t.                                                                                                      |
| l_sysid | Contains the ID of the node that already has a lock placed on the area defined by the fcntl subroutine. This field is returned only when the value of the <i>Command</i> parameter is F_GETLK.  |
| l_pid   | Contains the ID of a process that already has a lock placed on the area defined by the fcntl subroutine. This field is returned only when the value of the <i>Command</i> parameter is F_GETLK. |
| l_vfs   | Specifies the file system type of the node identified in the l_sysid field.                                                                                                                     |

## fullstat.h File

### Purpose

Defines the data structure returned by the **fullstat** subroutine.

### Description

The **/usr/include/sys/fullstat.h** file defines the data structure returned by the **fullstat** and **ffullstat** subroutines. This file also defines the *Command* parameters used by the **fullstat** and **ffullstat** subroutines. The **fullstat** structure contains the following fields:

**Note:** Time is measured in seconds since 00:00:00 GMT, January 1, 1970.

| Item            | Description                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| st_dev          | ID of device containing a directory entry for this file. The file serial number and the device ID uniquely identify the file within the system. |
| st_ino          | File serial number.                                                                                                                             |
| st_mode         | The mode of the file, as defined in the <b>/usr/include/sys/mode.h</b> file.                                                                    |
| st_nlink        | Number of links to file.                                                                                                                        |
| st_uid          | User ID of the owner of the file.                                                                                                               |
| st_gid          | Group ID of the file owner group.                                                                                                               |
| st_rdev         | ID of this device. This field is defined only for character or block special files.                                                             |
| st_size         | File size in bytes.                                                                                                                             |
| st_atime        | Time of last access.                                                                                                                            |
| st_mtime        | Time of last data modification.                                                                                                                 |
| st_ctime        | Time of last file status change.                                                                                                                |
| st_blksize      | Optimal block size for the file system.                                                                                                         |
| st_blocks       | Number of blocks actually allocated to the file.                                                                                                |
| st_vfstype      | File-system type as defined in the <b>vmount.h</b> file.                                                                                        |
| fst_type        | Type of v-node.                                                                                                                                 |
| fst_vfs         | Virtual file system ID.                                                                                                                         |
| fst_flag        | Indicates whether directory or file is a virtual mount point.                                                                                   |
| fst_i_gen       | Generation number of the i-node.                                                                                                                |
| fst_reserved[8] | Reserved.                                                                                                                                       |

The following fields are maintained for source-level compatibility with previous versions of the operating system:

## grp.h File

### Purpose

Describes group structure.

### Syntax

```
#include <grp.h>
```

### Description

The **grp.h** header declares the structure **group** that includes the following members:

```
char *gr_name the name of the group
gid_t gr_gid numerical group ID
char **gr_mem pointer to a null-terminated array of character pointers to member names
```

The **gid\_t** type is defined as described in the **sys/types.h** header file.

The following are declared as functions and may also be defined as macros. Function prototypes must be provided for use with an ISO C compiler.

```
struct group *getgrgid(gid_t);
struct group *getgrnam(const char *);
int getgrgid_r(gid_t, struct group *, char *, size_t, struct group **);
int getgrnam_r(const char *, struct group *, char *, size_t, struct group **);
struct group *getgrent(void);
void endgrent(void);
void setgrent(void);
```

getgrgid\_r subroutine

## iconv.h File

### Purpose

Defines types, macros, and subroutines for character code set conversion.

### Description

The **/usr/include/iconv.h** file defines types, subroutines, and macros used in character code-set conversion by the iconv family of subroutines and commands. The **iconv.h** file defines the **iconv\_t** data type.

**Related information:**

genxlt command

iconv command

## inode.h File

### Purpose

Describes a file system file or directory entry as it is listed on a disk.

### Syntax

```
#include <sys/types.h>
#include <sys/ino.h>
```

### Description

The **inode** file for an ordinary file or directory in a file system has the following structure defined by the **sys/ino.h** file format:

```
struct dinode
{
 /* generation number */
 ulong di_gen;
 /* mode_t returned by stat () */
 /* format,attributes and permission bits */
 mode_t di_mode;

 /* number of links to file(if 0,inode is available) */
 ushort di_nlink;

 /* accounting ID */
 ushort di_acct;

 /* user id of owner */
 uid_t di_uid;

 /* group id of owner */
 gid_t di_gid;

 /* size of file */
 off_t di_size;

 /* number of blocks actually used by file */
 ulong di_nblocks;

 /* time last modified */
 struct timestruc_t di_mtime_ts;

 /* time last accessed */
 struct timestruc_t di_atime_ts;

 /* time last changed inode */
 struct timestruc_t di_ctime_ts;

 /*defines for old time_t names */
#define di_mtime di_mtime_ts.tv_sec
#define di_atime di_atime_ts.tv_sec
#define di_ctime di_ctime_ts.tv_sec

 /* extended access control information */
 long di_acl; /* acl pointer */
#define ACL_INCORE (1<<31)
 ulong di_sec; /* reserved */
```

```

/* spares */
ulong di_rsrvd[5];

***** file type-dependent information ****/
/* size of private data in disk inode is D_PRIVATE.
 * location and size of fields depend on object type.
 */

## inttypes.h File

### Purpose

Contains fixed size integral types.

### Syntax

#include <inttypes.h>

## Description

The `inttypes.h` header includes definitions of, at least, the following types:

| Item                   | Description                                              |
|------------------------|----------------------------------------------------------|
| <code>int8_t</code>    | 8-bit signed integral type.                              |
| <code>int16_t</code>   | 16-bit signed integral type.                             |
| <code>int32_t</code>   | 32-bit signed integral type.                             |
| <code>int64_t</code>   | 64-bit signed integral type.                             |
| <code>uint8_t</code>   | 8-bit unsigned integral type.                            |
| <code>uint16_t</code>  | 16-bit unsigned integral type.                           |
| <code>uint32_t</code>  | 32-bit unsigned integral type.                           |
| <code>uint64_t</code>  | 64-bit unsigned integral type.                           |
| <code>intptr_t</code>  | Signed integral type large enough to hold any pointer.   |
| <code>uintptr_t</code> | Unsigned integral type large enough to hold any pointer. |

## ipc.h File

### Purpose

Describes the structures that are used by the subroutines that perform interprocess communications operations.

### Syntax

```
#include <sys/ipc.h>
```

### Description

The `ipc.h` file defines the following symbolic constants, types, and structures:

#### Symbolic Constants:

|                          |                                       |
|--------------------------|---------------------------------------|
| <code>IPC_CREAT</code>   | create entry if key doesn't exist     |
| <code>IPC_EXCL</code>    | fail if key exists                    |
| <code>IPC_NOWAIT</code>  | error if request must wait            |
| <code>IPC_PRIVATE</code> | private key                           |
| <code>IPC_RMID</code>    | remove identifier                     |
| <code>IPC_SET</code>     | set options                           |
| <code>IPC_STAT</code>    | get options                           |
| <code>IPC_ALLO</code>    | Centry currently allocated            |
| <code>IPC_R</code>       | read or receive permission            |
| <code>IPC_W</code>       | write or send permission              |
| <code>IPC_NOERROR</code> | truncates a message if too long       |
| <code>SHM_SIZE</code>    | change segment size (shared mem only) |

The structure `ipc_perm` contains the following members:

|                             |                   |                            |
|-----------------------------|-------------------|----------------------------|
| <code>uid_t</code>          | <code>uid</code>  | owner's user id            |
| <code>gid_t</code>          | <code>gid</code>  | owner's group id           |
| <code>uid_t</code>          | <code>cuid</code> | creator's user id          |
| <code>gid_t</code>          | <code>cgid</code> | creator's group id         |
| <code>mode_t</code>         | <code>mode</code> | access modes               |
| <code>unsigned short</code> | <code>seq</code>  | slot usage sequence number |
| <code>key_t</code>          | <code>key</code>  | key                        |

The types `uid_t`, `gid_t`, `mode_t`, and `key_t` are as defined in `<sys/types.h>`.

The following is declared as a function:

```
key_t ftok(const char *, int);
```

## iso646.h File

### Purpose

Provides alternate spellings.

### Syntax

```
#include <iso646.h>
```

### Description

The **iso646.h** header file defines the following eleven macros (on the left) that expand to the corresponding tokens (on the right):

|        |    |
|--------|----|
| and    | && |
| and_eq | &= |
| bitand | &  |
| bitor  |    |
| compl  | ~  |
| not    | !  |
| not_eq | != |
| or     |    |
| or_eq  | =  |
| xor    | ^  |
| xor_eq | ^= |

## ldr.h File

### Purpose

Describes the **ld\_info** and **ld\_xinfo** data types, along with associated loader entry points.

### Syntax

```
#include <sys/ldr.h>
```

### Description

The **/usr/include/sys/ldr.h** header file contains declarations of the **ld\_info** and **ld\_xinfo** data structures and the system loader entry points available to processes and kernel extensions.

The **ld\_info** structure describes a loadable module in the context of either tracing a process (with the **ptrace** system call) or examining a core file. The **ldr.h** file can define 2 variants of the **ld\_info** structure, one for describing 32-bit processes (**\_ld\_info32**) and one for describing 64-bit processes (**\_ld\_info64**). If the **\_\_LDINFO\_PTRACE32\_\_** symbol is defined, so is the **struct \_\_ld\_info32** type. If the **\_\_LDINFO\_PTRACE64\_\_** symbol is defined, so is the **struct \_\_ld\_info64** type. If the compilation mode is 32-bit and the **\_\_LDINFO\_PTRACE32\_\_** symbol is defined, the **struct \_\_ld\_info32** and **struct ld\_info** types are equivalent. If the compilation mode is 64-bit and the **\_\_LDINFO\_PTRACE64\_\_** symbol is defined, the **struct \_\_ld\_info64** and **struct ld\_info** types are equivalent.

When using **ptrace** in a 32-bit program to debug a 64-bit process, define **\_\_LDINFO\_PTRACE64\_\_**. When using **ptrace** in a 64-bit program to debug a 32-bit process, define **\_\_LDINFO\_PTRACE32\_\_**.

The types and sizes of these structures' fields depend on whether the compilation mode is 32-bit or 64-bit. The same field names are generated in both structure modes, with the exception that the 64-bit structure has an **ldinfo\_flags** field.

The **\_ld\_info32** and **\_ld\_info64** structures contain the following fields of the indicated sizes and types; when two types are listed, the first is used when the compilation mode is 32-bit and the second is used when the mode is 64-bit:

| Field and Description                                                                                                              | <b>_ld_info32</b>                                                                                     | <b>_ld_info64</b>                                                                                                 |
|------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>ldinfo_next</b><br>Offset from current entry of next entry, or zero if last entry.                                              | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> uint</li> </ul>           | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> uint</li> </ul>                       |
| <b>ldinfo_flags</b><br>Flags.                                                                                                      | <ul style="list-style-type: none"> <li><b>Size:</b> N/A</li> <li><b>Type:</b> N/A</li> </ul>          | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> uint</li> </ul>                       |
| <b>ldinfo_fd</b><br>File descriptor returned by ptrace to debugger.                                                                | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> int</li> </ul>            | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> int</li> </ul>                        |
| <b>ldinfo_core</b><br>Offset into core file of object. (Overlays the <b>ldinfo_fd</b> field.)                                      | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> int</li> </ul>            | <ul style="list-style-type: none"> <li><b>Size:</b> 8</li> <li><b>Type:</b> long long, long</li> </ul>            |
| <b>ldinfo_textorg</b><br>Effective address of the loaded program image, including the XCOFF headers.                               | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> void *, uint</li> </ul>   | <ul style="list-style-type: none"> <li><b>Size:</b> 8</li> <li><b>Type:</b> unsigned long long, void *</li> </ul> |
| <b>ldinfo_textsize</b><br>Length of loaded program image.                                                                          | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> int</li> </ul>            | <ul style="list-style-type: none"> <li><b>Size:</b> 8</li> <li><b>Type:</b> long long, long</li> </ul>            |
| <b>ldinfo_dataorg</b><br>Effective address of the start of data.                                                                   | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> void *, uint</li> </ul>   | <ul style="list-style-type: none"> <li><b>Size:</b> 8</li> <li><b>Type:</b> unsigned long long, void *</li> </ul> |
| <b>ldinfo_datasize</b><br>Size of data, including the <b>.bss</b> section.                                                         | <ul style="list-style-type: none"> <li><b>Size:</b> 4</li> <li><b>Type:</b> int</li> </ul>            | <ul style="list-style-type: none"> <li><b>Size:</b> 8</li> <li><b>Type:</b> long long, long</li> </ul>            |
| <b>ldinfo_filename</b><br>Nul-terminated path name followed by nul-terminated member name; member name is empty if not an archive. | <ul style="list-style-type: none"> <li><b>Size:</b> variable</li> <li><b>Type:</b> char[2]</li> </ul> | <ul style="list-style-type: none"> <li><b>Size:</b> variable</li> <li><b>Type:</b> char[2]</li> </ul>             |

The **ld\_xinfo** structure is similar to the **ld\_info** structure, but the **ld\_xinfo** structure has additional fields for modules defining thread-local storage. Furthermore, all fields are large enough to describe regions of a 64-bit process, so only a single variant of the **ld\_xinfo** structure exists.

The additional fields in the **ld\_xinfo** structure are the following:

| Field                         | Description                                                                |
|-------------------------------|----------------------------------------------------------------------------|
| <code>ldinfo_tdatasize</code> | Size of the <code>.tdata</code> section.                                   |
| <code>ldinfo_tbssize</code>   | Size of the <code>.tbss</code> section.                                    |
| <code>ldinfo_tdataorg</code>  | Effective address of the initialization template for <code>.tdata</code> . |
| <code>ldinfo_tdataoff</code>  | Offset of the module's thread-local storage in its region.                 |
| <code>ldinfo_tls_rnum</code>  | Thread-local storage region number.                                        |

In addition, the `ldinfo_filename` field has a different interpretation in the `ld_xinfo` structure. The value of this field in the `ld_xinfo` structure is an offset from the beginning of the structure to a null-terminated path name followed by null-terminated member name.

The `ldr.h` header declares the following functions:

```
int kmod_load(caddr_t path, uint flags, caddr_t libpath, mid_t *kmid);
int kmod_unload(mid_t kmid, uint flags);
void (*kmod_encrypt(mid_t kmid, uint flags))();
int ld_info(int _flags, pid_t _pid, void *_buffer, unsigned int _length);
__LOAD_T *load(char *_filenameparm, uint _flags, char *_libpathparm);
int loadbind(int _lflags, void *_exporter, void *_importer);
int unload(void *_function);
int loadquery(int _lflags, void *_buffer, unsigned int _length);
__handler_t * __lazySetErrorHandler(__handler_t *fp);
```

## limits.h File

### Purpose

Defines implementation limits identified by IEEE POSIX 1003.

### Description

The `limits.h` file contains definitions required by the ANSI X3.159-198x Programming Language C Standard and the Institute of Electrical and Electronics Engineers (IEEE) P1003.1 Portable Operating System Interface for Computer Environments (POSIX) standard.

The constants required by the ANSI C Standard describe the sizes of basic data types, as follows:

| Symbol                 | Value          | Explanation                                                  |
|------------------------|----------------|--------------------------------------------------------------|
| <code>CHAR_BIT</code>  | 8              | Number of bits in a variable of type <code>char</code>       |
| <code>CHAR_MAX</code>  | 255            | Maximum value of a variable of type <code>char</code>        |
| <code>CHAR_MIN</code>  | 0              | Minimum value of a variable of type <code>char</code>        |
| <code>INT_MAX</code>   | 2,147,483,647  | Maximum value of a variable of type <code>int</code>         |
| <code>INT_MIN</code>   | -2,147,483,648 | Minimum value of a variable of type <code>int</code>         |
| <code>LONG_MAX</code>  | 2,147,483,647  | Maximum value of a variable of type <code>long</code>        |
| <code>LONG_MIN</code>  | -2,147,483,648 | Minimum value of a variable of type <code>long</code>        |
| <code>SCHAR_MAX</code> | 127            | Maximum value of a variable of type <code>signed char</code> |
| <code>SCHAR_MIN</code> | -128           | Minimum value of a variable of type <code>signed char</code> |
| <code>SHRT_MAX</code>  | 32,767         | Maximum value of a variable of type <code>short</code>       |
| <code>SHRT_MIN</code>  | -32,768        | Minimum value of a variable of type <code>short</code>       |

| Symbol    | Value         | Explanation                                        |
|-----------|---------------|----------------------------------------------------|
| UCHAR_MAX | 255           | Maximum value of a variable of type unsigned char  |
| UINT_MAX  | 4,294,967,295 | Maximum value of a variable of type unsigned int   |
| ULONG_MAX | 4,294,967,295 | Maximum value of a variable of type unsigned long  |
| USHRT_MAX | 65,535        | Maximum value of a variable of type unsigned short |

### Run-Time Invariant Values

The first set of values required by POSIX, run-time invariant values, are simple constants determined by basic operating system data-structure sizes.

| Symbol      | Value     | Explanation                                                                                                |
|-------------|-----------|------------------------------------------------------------------------------------------------------------|
| MAX_INPUT   | 512       | No fewer than the number of bytes specified by the MAX_INPUT symbol are allowed in a terminal input queue. |
| NGROUPS_MAX | 2048      | Maximum size of the concurrent group list.                                                                 |
| PASS_MAX    | 255       | Maximum number of bytes in a password (not including the null terminator).                                 |
| PID_MAX     | INT_MAX   | Maximum value for a processID.                                                                             |
| UID_MAX     | ULONG_MAX | Maximum value for a user or group ID.                                                                      |

### Run-Time Invariant Values (Possibly Indeterminate)

The second set of run-time invariant values required by POSIX specify values that might vary, especially due to system load, but that can be attained on a lightly loaded system.

| Symbol  | Value   | Explanation                                                                                                                                                                 |
|---------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARG_MAX | 1048576 | Maximum length (in bytes) of arguments for the <code>exec</code> subroutine, including the environment. This is a default value that can be configured to a different size. |

**Note:** The argument list and environment are allowed to consume all of the user data segment.

| Symbol        | Value | Explanation                                                                      |
|---------------|-------|----------------------------------------------------------------------------------|
| CHILD_MAX     | 40    | Maximum number of simultaneous processes per user ID                             |
| MAX_CANON     | 256   | Maximum number of bytes in a canonical input line                                |
| OPEN_MAX      | 65534 | Maximum number of files that one process can have open at any given time         |
| CHRS_OPEN_MAX | 65000 | The maximum number of file descriptors to fit in the checkpoint/restart segment. |

### Path-Name Variable Values

The third set of values required by POSIX, path-name variable values, represent constraints imposed by the file system on file path names. Further constraints on these values might be imposed by the underlying file-system implementation. Use the `pathconf` or `fpathconf` subroutine to determine any file-implementation characteristics specific to the underlying file system.

| Symbol   | Value     | Explanation                                                                          |
|----------|-----------|--------------------------------------------------------------------------------------|
| NAME_MAX | Undefined | Maximum number of bytes in a file component name (not including the null terminator) |
| PATH_MAX | 512       | Maximum number of bytes in a path name (not including the null terminator)           |

## Run-Time Increasable Values

The fourth set of values required by POSIX specify values that might be increased at run time. Use the **pathconf** or **fpathconf** subroutine to determine any file-implementation characteristics specific to the underlying file system.

| Item     | Description |                                                                           |
|----------|-------------|---------------------------------------------------------------------------|
| Symbol   | Value       | Explanation                                                               |
| LINK_MAX | 32,767      | Maximum value of a file's link count ( <b>SHRT_MAX</b> ).                 |
| PIPE_BUF | 32,768      | Maximum number of bytes guaranteed to be written automatically to a pipe. |

## libperfstat.h File

### Purpose

Describes the structures and constants used by the **libperfstat** API subroutines.

### Syntax

```
#include <libperfstat.h>
```

### Description

The **libperfstat.h** file defines the following symbolic constants, types, and structures:

| Item                | Description                                      |
|---------------------|--------------------------------------------------|
| IDENTIFIER_LENGTH   | Length of strings included in the structures.    |
| FIRST_LOGICALVOLUME | Pseudo-name for the first logical volume.        |
| FIRST_VOLUMEGROUP   | Pseudo-name for the first volume group.          |
| FIRST_CPU           | Pseudo-name for the first logical processor.     |
| FIRST_DISK          | Pseudo-name for the first disk.                  |
| FIRST_DISKADAPTER   | Pseudo-name for the first disk adapter.          |
| FIRST_FCADAPTER     | Pseudo-name for the first fiber channel adapter. |
| FIRST_DISKPATH      | Pseudo-name for the first disk path.             |
| FIRST_NETINTERFACE  | Pseudo-name for the first network interface.     |
| FIRST_PAGINGSPACE   | Pseudo-name for the first paging space.          |
| FIRST_PROTOCOL      | Pseudo-name for the first protocol.              |
| FIRST_NETADAPTER    | pseudo-name for the first network adapter.       |
| FIRST_NETBUFFER     | Pseudo-name for the first network buffer size.   |
| FIRST_PSIZE         | Pseudo-name for the first paging size.           |

| Item                   | Description                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------|
| FIRST_TAPE             | Pseudo-name for the first tape.                                                                                         |
| FIRST_WPARNAME         | Pseudo-name for the first.WPAR                                                                                          |
| FIRST_WPARID           | Pseudo-id for the first.WPAR                                                                                            |
| FIRST_CLUSTERNAME      | Pseudo-name for the first cluster.                                                                                      |
| FIRST_NODENAME         | Pseudo-name for the first node in the cluster.                                                                          |
| FIRST_HFI              | Pseudo-name for the first host fabric interface (HFI).                                                                  |
| FIRST_SEA "ent0"       | Pseudo-name for the first shared Ethernet adapter (SEA) adapter. A valid SEA name must be entered.                      |
| FIRST_VFCHOST ""       | Pseudo-name for the first virtual FC adapter.                                                                           |
| FIRST_VHOST ""         | Pseudo-name for the first virtual small computer system interface (SCSI) or serial attached SCSI (SAS) adapter.         |
| FIRST_VTD ""           | Pseudo-name for the first virtual target device.                                                                        |
| FIRST_WINDOW           | Pseudo-id for the first HFI window.                                                                                     |
| PAGE_4K                | Pseudo-name for 4 kilobyte page size.                                                                                   |
| PAGE_64K               | Pseudo name for 64 kilobyte page size.                                                                                  |
| PAGE_16M               | Pseudo-name for 16 megabyte page size.                                                                                  |
| PAGE_16G               | Pseudo-name for 16 gigabyte page size.                                                                                  |
| PERFSTAT_ENABLE        | Mask for <code>perfstat_config</code> to start the statistics collection.                                               |
| PERFSTAT_DISABLE       | Mask for <code>perfstat_config</code> to disable statistics collection.                                                 |
| PERFSTAT_LV            | Mask for <code>perfstat_config</code> to indicate logical volume component.                                             |
| PERFSTAT_CLUSTER_STATS | Mask for <code>perfstat_config</code> to indicate cluster statistics.                                                   |
| PERFSTAT_HFISTATS      | Mask for <code>perfstat_config</code> to indicate HFI statistics.                                                       |
| PERFSTAT_SIZE          | Size of the adapter name.                                                                                               |
| FLUSH_CPUTOTAL         | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_cpu_total_t</code> .             |
| FLUSH_DISK             | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_disk_t</code> .                  |
| RESET_DISK_MIN_MAX     | Mask for <code>perfstat_partial_reset</code> to reset minimum and maximum service and wait time statistics of the disk. |
| FLUSH_DISKADAPTER      | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_diskadapter_t</code> .           |
| FLUSH_DISKPATH         | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_diskpath_t</code> .              |
| FLUSH_PAGINGSPACE      | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_pagingspace_t</code> .           |
| FLUSH_NETINTERFACE     | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_netinterface_t</code> .          |
| FLUSH_LOGICALVOLUME    | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_logicalvolume_t</code> .         |
| FLUSH_VOLUMEGROUP      | Mask for <code>perfstat_partial_reset</code> to flush cached fields for <code>perfstat_volumegroup_t</code> .           |

The `perfstat_id_t` structure contains the following members:

| Item                          | Description             |
|-------------------------------|-------------------------|
| char name [IDENTIFIER_LENGTH] | Name of the identifier. |

The `perfstat_id_wpar_t` structure contains the following members:

| Item                          | Description                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| wparidSpecifier spec          | Specifies the input type. It can be WPARNAME, WPARID, or RSETHANDLE.                                                                                                                                                                                                                                                                |
| union u                       | Specifies the WPAR identifier. The <code>union u</code> variable contains the following members: <ul style="list-style-type: none"> <li>• <code>cid_t wpar_id</code>: WPAR ID</li> <li>• <code>rsethandle_t rset</code>: resource set handle</li> <li>• <code>char wparname[MAXCORRALNAMELEN+1]</code>: name of the WPAR</li> </ul> |
| char name [IDENTIFIER_LENGTH] | Specifies the component identifier.                                                                                                                                                                                                                                                                                                 |

The **perfstat\_id\_node\_t** structure contains the following members:

| Item                          | Description                                                                                                                                                                      |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nodeidSpecifier spec          | Specifies the input type. It must be NODENAME for perfstat_subsystem_node() interfaces. It must be CLUSTERNAME for perfstat_cluster_total() and perfstat_node_list() interfaces. |
| union u                       | Specifies the WPAR identifier. The <b>union u</b> variable contains the following members:                                                                                       |
| char name [IDENTIFIER_LENGTH] | <ul style="list-style-type: none"> <li>• char nodename [MAXHOSTNAMELEN]: name of the node/cluster.</li> </ul>                                                                    |
|                               | Specifies the component identifier.                                                                                                                                              |

The **perfstat\_psize\_t** structure contains the following members:

| Item          | Description              |
|---------------|--------------------------|
| psize_t psize | Specifies the page size. |

Some members of the following structures are retrieved only once and stored in a memory cache by the library. A call to the **perfstat\_reset** structure or the **perfstat\_partial\_reset** structure will flush those members. When possible, it is preferable to use the **perfstat\_partial\_reset** structure instead of the **perfstat\_reset** structure.

The **perfstat\_cpu\_t** structure contains the following members:

| Item                          | Description                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------|
| char name [IDENTIFIER_LENGTH] | Logical processor name (processor0, processor1, ..).                                           |
| State                         | State of CPU (offline or online).                                                              |
| u_longlong_t user             | Raw number of clock ticks spent in user mode.                                                  |
| u_longlong_t sys              | Raw number of clock ticks spent in system mode.                                                |
| u_longlong_t idle             | Raw number of clock ticks spent idle.                                                          |
| u_longlong_t wait             | Raw number of clock ticks spent waiting for I/O.                                               |
| _longlong_t pswitch           | Number of context switches (changes of currently running process).                             |
| u_longlong_t syscall          | Number of system calls executed.                                                               |
| u_longlong_t sysread          | Number of read system calls executed.                                                          |
| u_longlong_t syswrite         | Number of write system calls executed.                                                         |
| u_longlong_t sysfork          | Number of fork system call executed.                                                           |
| u_longlong_t sysexec          | Number of exec system call executed.                                                           |
| u_longlong_t readch           | Number of characters transferred with read system call.                                        |
| u_longlong_t writech          | Number of characters transferred with write system call.                                       |
| u_longlong_t bread            | Number of block reads.                                                                         |
| u_longlong_t bwrite           | Number of block writes.                                                                        |
| u_longlong_t lread            | Number of logical read requests.                                                               |
| u_longlong_t lwrite           | Number of logical write requests.                                                              |
| u_longlong_t phread           | Number of physical reads (reads on raw device).                                                |
| u_longlong_t phwrite          | Number of physical writes (writes on raw device).                                              |
| u_longlong_t igin             | Number of inode lookups.                                                                       |
| u_longlong_t namei            | Number of vnode lookup from a path name.                                                       |
| u_longlong_t dirblk           | Number of 512-byte blocks reads by the directory search routine to locate an entry for a file. |
| u_longlong_t msg              | Number of interprocess communication (IPC) message operations.                                 |
| u_longlong_t sema             | Number of IPC semaphore operations.                                                            |
| u_longlong_t minfaults        | Number of page faults with no I/O.                                                             |
| u_longlong_t majfaults        | Number of page faults with disk I/O.                                                           |
| u_longlong_t puser            | Raw number of physical processor tics in user mode.                                            |
| u_longlong_t psys             | Raw number of physical processor tics in system mode.                                          |
| u_longlong_t pidle            | Raw number of physical processor tics idle.                                                    |
| u_longlong_t pwait            | Raw number of physical processor tics waiting for I/O.                                         |
| u_longlong_t redisp_sd0       | Number of thread redispatches within the scheduler affinity domain 0.                          |
| u_longlong_t redisp_sd1       | Number of thread redispatches within the scheduler affinity domain 1.                          |

| Item                                | Description                                                                                                            |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t redisp_sd2             | Number of thread redispatches within the scheduler affinity domain 2.                                                  |
| u_longlong_t redisp_sd3             | Number of thread redispatches within the scheduler affinity domain 3.                                                  |
| u_longlong_t redisp_sd4             | Number of thread redispatches within the scheduler affinity domain 4.                                                  |
| u_longlong_t redisp_sd5             | Number of thread redispatches within the scheduler affinity domain 5.                                                  |
| u_longlong_t migration_push         | Number of thread migrations from the local runque to another queue due to starvation load balancing.                   |
| u_longlong_t migration_S3grq        | Number of thread migrations from the global runque to the local runque resulting in a move across scheduling domain 3. |
| u_longlong_t migration_S3pull       | Number of thread migrations from another processor's runque resulting in a move across scheduling domain 3.            |
| u_longlong_t invol_cswitch          | Number of involuntary thread context switches.                                                                         |
| u_longlong_t vol_cswitch            | Number of voluntary thread context switches.                                                                           |
| u_longlong_t runque                 | Number of threads on the runque.                                                                                       |
| u_longlong_t bound                  | Number of bound threads.                                                                                               |
| u_longlong_t decrintrs              | Number of decrementer interrupts.                                                                                      |
| u_longlong_t mpctrintrs             | Number of received interrupts for MPC.                                                                                 |
| u_longlong_t mpccintrs              | Number of sent interrupts for MPC.                                                                                     |
| u_longlong_t devintrs               | Number of device interrupts.                                                                                           |
| u_longlong_t softintrs              | Number of offlevel handlers called.                                                                                    |
| u_longlong_t phantomintrs           | Number of phantom interrupts.                                                                                          |
| u_longlong_t idle_donated_purr      | Number of idle cycles donated by a dedicated partition enabled for donation.                                           |
| u_longlong_t idle_donated_spurr     | Number of idle spurr cycles donated by a dedicated partition enabled for donation.                                     |
| u_longlong_t busy_donated_purr      | Number of busy cycles donated by a dedicated partition enabled for donation.                                           |
| u_longlong_t busy_donated_spurr     | Number of busy spurr cycles donated by a dedicated partition enabled for donation.                                     |
| u_longlong_t idle_stolen_purr       | Number of idle cycles stolen by the hypervisor from a dedicated partition.                                             |
| u_longlong_t idle_stolen_spurr      | Number of idle spurr cycles stolen by the hypervisor from a dedicated partition.                                       |
| u_longlong_t busy_stolen_purr       | Number of busy cycles stolen by the hypervisor from a dedicated partition.                                             |
| u_longlong_t busy_stolen_spurr      | Number of busy spurr cycles stolen by the hypervisor from a dedicated partition.                                       |
| u_longlong_t shcpus_in_sys          | Number of physical processors allocated for shared processor use, across all shared processors pools.                  |
| u_longlong_t entitled_pool_capacity | Entitled processor capacity of partition's pool                                                                        |
| u_longlong_t pool_max_time          | Summation of maximum time that can be consumed by the pool (nano seconds)                                              |
| u_longlong_t pool_busy_time         | Summation of busy (non-idle) time accumulated across all partitions in the pool (nano seconds)                         |
| u_longlong_t pool_scaled_busy_time  | Scaled summation of busy (non-idle) time accumulated across all partitions in the pool (nano seconds)                  |
| u_longlong_t shcpu_tot_time         | Summation of total time across all physical processors allocated for shared processor use (nano seconds)               |
| u_longlong_t shcpu_busy_time        | Summation of busy (non-idle) time accumulated across all shared processor partitions (nano seconds)                    |
| u_longlong_t shcpu_scaled_busy_time | Scaled summation of busy time accumulated across all shared processor partitions (nano seconds)                        |
| int ams_pool_id                     | AMS pool ID of the pool the LPAR belongs to                                                                            |
| int var_mem_weight                  | Variable memory capacity weight                                                                                        |
| u_longlong_t iome                   | I/O memory entitlement of the partition in bytes                                                                       |
| u_longlong_t pmem                   | Physical memory currently backing the partition's logical memory in bytes                                              |
| u_longlong_t hpi                    | Number of hypervisor page-ins                                                                                          |
| u_longlong_t hpit                   | Time spent in hypervisor page-ins (in nanoseconds)                                                                     |
| u_longlong_t hypv_pagesize          | Hypervisor page size in KB                                                                                             |
| uint online_lcpus                   | Number of online logical processors                                                                                    |
| uint smt_thrds                      | Number of SMT threads                                                                                                  |

The **perfstat\_cpu\_total\_wpar\_t** structure contains the following members:

| Item                                | Description                                                                                                                                                                                                   |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int ncpus                           | Number of active logical processors in Global environment.                                                                                                                                                    |
| char description[IDENTIFIER_LENGTH] | Processor description (type or official name).                                                                                                                                                                |
| u_longlong_t processorHZ            | Processor speed, in Hz.                                                                                                                                                                                       |
| u_longlong_t pswitch                | Number of process switches (change in running process).                                                                                                                                                       |
| u_longlong_t sysfork                | Number of forks system calls that are run.                                                                                                                                                                    |
| u_longlong_t loadavg[3]             | (1<< SBITS) times the average number of runnable processes during the last 1, 5, and 15 minutes. To calculate the load average, divide the numbers by (1<< SBITS). SBITS is defined in the <sys/proc.h> file. |
| u_longlong_t runque                 | Length of the run queue (processes ready).                                                                                                                                                                    |
| u_longlong_t swpque                 | Length of the swap queue (processes waiting to be paged in).                                                                                                                                                  |
| u_longlong_t runocc                 | Updated whenever a runque is updated or occupied. This structure can be used to compute the simple average of ready processes.                                                                                |
| u_longlong_t swpocc                 | Updated whenever a swpque is updated or occupied. This structure can be used to compute the simple average processes waiting to be paged in.                                                                  |
| u_longlong_t puser                  | Raw number of physical processor ticks in user mode.                                                                                                                                                          |
| u_longlong_t psys                   | Raw number of physical processor ticks in system mode.                                                                                                                                                        |
| u_longlong_t pidle                  | Raw number of physical processor ticks idle.                                                                                                                                                                  |
| u_longlong_t pwait                  | Raw number of physical processor ticks waiting for I/O.                                                                                                                                                       |
| int ncpus_cfg                       | Number of configured processors in the system.                                                                                                                                                                |
| u_longlong_t syscall                | Number of system calls that are run.                                                                                                                                                                          |
| u_longlong_t sysread                | Number of read system calls that are run.                                                                                                                                                                     |
| u_longlong_t syswrite               | Number of write system calls that are run.                                                                                                                                                                    |
| u_longlong_t sysexec                | Number of execs system calls that are run.                                                                                                                                                                    |
| u_longlong_t readch                 | Number of characters transferred with read system call.                                                                                                                                                       |
| u_longlong_t writech                | Number of characters transferred with write system call.                                                                                                                                                      |
| u_longlong_t devintrs               | Number of device interrupts.                                                                                                                                                                                  |
| u_longlong_t softintrs              | Number of software interrupts.                                                                                                                                                                                |
| u_longlong_t bread                  | Number of blocks read.                                                                                                                                                                                        |
| u_longlong_t bwrite                 | Number of blocks written.                                                                                                                                                                                     |
| u_longlong_t lread                  | Number of logical read requests.                                                                                                                                                                              |
| u_longlong_t lwrite                 | Number of logical write requests.                                                                                                                                                                             |
| u_longlong_t phread                 | Number of physical reads (reads on raw devices).                                                                                                                                                              |
| u_longlong_t phwrite                | Number of physical writes (writes on raw devices).                                                                                                                                                            |
| u_longlong_t iget                   | Number of inode lookups.                                                                                                                                                                                      |
| u_longlong_t namei                  | Number of vnode lookup from a path name.                                                                                                                                                                      |
| u_longlong_t dirblk                 | Number of 512-byte blocks read by the directory search routine to locate an entry for a file.                                                                                                                 |
| u_longlong_t msg                    | Number of IPC message operations.                                                                                                                                                                             |
| u_longlong_t sema                   | Number of IPC semaphore operations.                                                                                                                                                                           |
| u_longlong_t ksched                 | Number of kernel processes created.                                                                                                                                                                           |
| u_longlong_t koverf                 | Kernel process creation attempts when the configuration limit of processes has been reached or the user has forked to the maximum limit.                                                                      |
| u_longlong_t kexit                  | Number of kernel processes that became zombie processes.                                                                                                                                                      |

The **perfstat\_cpu\_total\_t** structure contains the following members:

| Item                                 | Description                                                       |
|--------------------------------------|-------------------------------------------------------------------|
| int ncpus                            | Number of active logical processors.                              |
| int ncpus_cfg                        | Number of configured processors.                                  |
| char description [IDENTIFIER_LENGTH] | Processor description (type/official name).                       |
| u_longlong_t processorHZ             | Processor speed in Hz.                                            |
| u_longlong_t user                    | Raw total number of clock ticks spent in user mode.               |
| u_longlong_t sys                     | Raw total number of clock ticks spent in system mode.             |
| u_longlong_t idle                    | Raw total number of clock ticks spent idle.                       |
| u_longlong_t wait                    | Raw total number of clock ticks spent waiting for I/O.            |
| u_longlong_t pswitch                 | Number of process switches (change in currently running process). |
| u_longlong_t syscall                 | Number of system calls executed.                                  |
| u_longlong_t sysread                 | Number of read system calls executed.                             |

| Item                           | Description                                                                                                                                                                                                       |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t syswrite          | Number of write system calls executed.                                                                                                                                                                            |
| u_longlong_t sysfork           | Number of forks system calls executed.                                                                                                                                                                            |
| u_longlong_t sysexec           | Number of execs system calls executed.                                                                                                                                                                            |
| u_longlong_t readch            | Number of characters transferred with read system call.                                                                                                                                                           |
| u_longlong_t wriech            | Number of characters transferred with write system call.                                                                                                                                                          |
| u_longlong_t devintrs          | Number of device interrupts.                                                                                                                                                                                      |
| u_longlong_t softintrs         | Number of software interrupts.                                                                                                                                                                                    |
| ime_t lboot                    | Number of ticks since last reboot.                                                                                                                                                                                |
| u_longlong_t loadavg[3]        | (1<< SBITS) times the average number of runnable processes during the last 1, 5 and 15 minutes. To calculate the load average, divide the numbers by (1<< SBITS). SBITS is defined in the <sys/proc.h> file.      |
| u_longlong_t runque            | Length of the run queue (processes ready).                                                                                                                                                                        |
| u_longlong_t swpque            | Length of the swap queue (processes waiting to be paged in).                                                                                                                                                      |
| u_longlong_t bread             | Number of blocks read.                                                                                                                                                                                            |
| u_longlong_t bwrite            | Number of blocks written.                                                                                                                                                                                         |
| u_longlong_t lread             | Number of logical read requests.                                                                                                                                                                                  |
| u_longlong_t lwrite            | Number of logical write requests.                                                                                                                                                                                 |
| u_longlong_t phread            | Number of physical reads (reads on raw devices).                                                                                                                                                                  |
| u_longlong_t phwrite           | Number of physical writes (writes on raw devices).                                                                                                                                                                |
| u_longlong_t runocc            | Updated whenever runque is updated. For example, when the run queue is occupied. This can be used to compute the simple average of ready processes.                                                               |
| u_longlong_t swpocc            | Updated whenever swpque is updated. For example, when the swpqueue is occupied. This can be used to compute the simple average processes waiting to be paged in.                                                  |
| u_longlong_t iget              | Number of inode lookups.                                                                                                                                                                                          |
| u_longlong_t namei             | Number of vnode lookup from a path name.                                                                                                                                                                          |
| u_longlong_t dirblk            | Number of 512-byte blocks reads by the directory search routine to locate an entry for a file.                                                                                                                    |
| u_longlong_t msg               | Number of IPC message operations.                                                                                                                                                                                 |
| u_longlong_t sema              | Number of IPC semaphore operations.                                                                                                                                                                               |
| u_longlong_t rcvint            | Number of tty receive interrupts.                                                                                                                                                                                 |
| u_longlong_t xmtint            | Number of tty transmit interrupts.                                                                                                                                                                                |
| u_longlong_t mdmint            | Number of modem interrupts.                                                                                                                                                                                       |
| u_longlong_t tty_rawinch       | Number of raw input characters.                                                                                                                                                                                   |
| u_longlong_t tty_caninch       | Number of canonical input characters (always zero).                                                                                                                                                               |
| u_longlong_t tty_rawoutch      | Number of raw output characters.                                                                                                                                                                                  |
| u_longlong_t ksched            | Number of kernel processes created.                                                                                                                                                                               |
| u_longlong_t koverf            | Number of kernel process creation attempts where: <ul style="list-style-type: none"> <li>• the user has forked to their maximum limit</li> <li>• the configuration limit of processes has been reached</li> </ul> |
| u_longlong_t kexit             | Number of kernel processes that became zombies.                                                                                                                                                                   |
| u_longlong_t rbread            | Number of remote read requests.                                                                                                                                                                                   |
| u_longlong_t rbread            | Number of remote read requests.                                                                                                                                                                                   |
| u_longlong_t rbwrt             | Number of remote writes.                                                                                                                                                                                          |
| u_longlong_t rcwrt             | Number of cached remote writes.                                                                                                                                                                                   |
| u_longlong_t traps             | Number of traps.                                                                                                                                                                                                  |
| int ncpus_high                 | Index of highest processor online.                                                                                                                                                                                |
| u_longlong_t puser             | Raw number of physical processor tics in user mode.                                                                                                                                                               |
| u_longlong_t psys_raw          | Number of physical processor tics in system mode.                                                                                                                                                                 |
| u_longlong_t pidle_raw         | Number of physical processor tics idle.                                                                                                                                                                           |
| u_longlong_t pwait_raw         | Number of physical processor tics waiting for I/O.                                                                                                                                                                |
| u_longlong_t decreintrs        | Number of decrementer interrupts.                                                                                                                                                                                 |
| u_longlong_t mpcintrs          | Number of received interrupts for MPC.                                                                                                                                                                            |
| u_longlong_t mpccintrs         | Number of sent interrupts for MPC.                                                                                                                                                                                |
| u_longlong_t phantomintrs      | Number of phantom interrupts.                                                                                                                                                                                     |
| u_longlong_t idle_donated_purr | Number of idle cycles donated by a dedicated partition enabled for donation.                                                                                                                                      |

| Item                            | Description                                                                        |
|---------------------------------|------------------------------------------------------------------------------------|
| u_longlong_t idle_donated_spurr | Number of idle spurr cycles donated by a dedicated partition enabled for donation. |
| u_longlong_t busy_donated_purr  | Number of busy cycles donated by a dedicated partition enabled for donation.       |
| u_longlong_t busy_donated_spurr | Number of busy spurr cycles donated by a dedicated partition enabled for donation. |
| u_longlong_t idle_stolen_purr   | Number of idle cycles stolen by the hypervisor from a dedicated partition.         |
| u_longlong_t idle_stolen_spurr  | Number of idle spurr cycles stolen by the hypervisor from a dedicated partition.   |
| u_longlong_t busy_stolen_purr   | Number of busy cycles stolen by the hypervisor from a dedicated partition.         |
| u_longlong_t busy_stolen_spurr  | Number of busy spurr cycles stolen by the hypervisor from a dedicated partition.   |
| short iowait                    | Number of processes that are asleep waiting for buffered I/O.                      |
| short physio                    | Number of processes waiting for raw I/O.                                           |
| longlong_t twait                | Number of threads that are waiting for file system direct (cio).                   |
| u_longlong_t hpi                | Number of hypervisor page-ins.                                                     |
| u_longlong_t hpit               | Time spent in hypervisor page-ins (in nanoseconds).                                |

The description and speed members of the **perfstat\_cpu\_total\_t** structure are stored in the information cache. They can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_CPUTOTAL)`

The **perfstat\_rawdata\_t** structure contains the following members:

| Item               | Description                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| int type           | Holds one of the following defined values:                                                                                                                                             |
|                    | <ul style="list-style-type: none"> <li>• #define UTIL_CPU_TOTAL 10</li> <li>• #define UTIL_CPU 11</li> <li>• #define UTIL_PROCESS 12</li> <li>• #define SHARED_POOL_UTIL 13</li> </ul> |
| perfstat_id_t name | Name element.                                                                                                                                                                          |
| void *curstat      | Pointer to the data buffer.                                                                                                                                                            |
| void *prevstat     | Pointer to the data buffer.                                                                                                                                                            |
| int sizeof_data    | Size of the stat buffer.                                                                                                                                                               |
| int cur_elems      | Number of current elements.                                                                                                                                                            |
| int prev_elems     | Number of previous elements.                                                                                                                                                           |

The **perfstat\_partition\_total\_t** structure contains the following members:

| Item                           | Description                                                                              |
|--------------------------------|------------------------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]   | Name [IDENTIFIER_LENGTH].                                                                |
| perfstat_partition_type_t type | Set of bits describing partition type.                                                   |
| int lpar_id                    | Logical partition identifier.                                                            |
| int group_id                   | Identifier of the LPAR group this partition is a member of.                              |
| int pool_id                    | Identifier of the shared pool of physical processors this partition is a member of.      |
| int online_cpus                | Number of virtual processors currently online on the partition.                          |
| int max_cpus                   | Maximum number of virtual processors this partition can ever have.                       |
| int min_cpus                   | Minimum number of virtual processors this partition must have.                           |
| purr_counter                   | Number of purr cycles spent in user and kernel mode.                                     |
| real_free                      | Free real memory (in 4 KB pages).                                                        |
| real_avail                     | Number of pages (in 4 KB pages) of memory available without paging out working segments. |
| spurr_counter                  | Number of spurr cycles spent in user and kernel mode.                                    |
| u_longlong_t online_memory     | Amount of memory currently online.                                                       |

| Item                                 | Description                                                                                                                                                                                           |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t max_memory              | Maximum amount of memory this partition can ever have.                                                                                                                                                |
| u_longlong_t min_memory              | Minimum amount of memory this partition must have.                                                                                                                                                    |
| int entitled_proc_capacity           | Number of processor units this partition is entitled to receive.                                                                                                                                      |
| int max_proc_capacity                | Maximum number of processor units this partition can ever have.                                                                                                                                       |
| int min_proc_capacity                | Minimum number of processor units this partition must have.                                                                                                                                           |
| int proc_capacity_increment          | Increment value to the entitled capacity.                                                                                                                                                             |
| int unalloc_proc_capacity            | Unallocated processor units in the shared processor pool to which this partition belongs.                                                                                                             |
| int var_proc_capacity_weight         | Unallocated variable processor capacity weight units in the shared processor pool to which this partition belongs.                                                                                    |
| int unalloc_var_proc_capacity_weight | Number of variable processor capacity weight units currently unallocated in the shared processor pool this partition belongs to.                                                                      |
| int online_phys_cpus_sys             | Number of physical processors currently active in the system containing this partition.                                                                                                               |
| int max_phys_cpus_sys                | Maximum number of physical processors in the system containing this partition.                                                                                                                        |
| int phys_cpus_pool                   | Available physicalprocessors in the shared processor pool to which this partition belongs.                                                                                                            |
| u_longlong_t puser                   | Raw number of physical processor ticks in user mode.                                                                                                                                                  |
| u_longlong_t psys                    | Raw number of physical processor ticks in system mode.                                                                                                                                                |
| u_longlong_t pidle                   | Raw number of physical processor ticks idle.                                                                                                                                                          |
| u_longlong_t pwait                   | Raw number of physical processor ticks waiting for I/O.                                                                                                                                               |
| u_longlong_t pool_idle_time          | The summation of idle time (in nanoseconds) accumulated across all partitions in the shared processor pool to which this partition belongs.                                                           |
| u_longlong_t phantintrs              | Number of phantom interrupts.                                                                                                                                                                         |
| u_longlong_t invol_virt_cswitch      | Number involuntary virtual processor context switches.                                                                                                                                                |
| u_longlong_t vol_virt_cswitch        | Number voluntary virtual processor context switches.                                                                                                                                                  |
| u_longlong_t timebase_last           | Most recent processor time base timestamp.                                                                                                                                                            |
| u_longlong_t reserved_pages          | Number of 16 GB pages; cannot participate in DR operations.                                                                                                                                           |
| u_longlong_t reserved_pagesize       | 16 GB pagesize; cannot participate in DR operations.                                                                                                                                                  |
| u_longlong_t idle_donated_purr       | Number of idle cycles donated by a dedicated partition enabled for donation.                                                                                                                          |
| u_longlong_t idle_donated_spurr      | Number of idle spurr cycles donated by a dedicated partition enabled for donation.                                                                                                                    |
| u_longlong_t busy_donated_purr       | Number of busy cycles donated by a dedicated partition enabled for donation.                                                                                                                          |
| u_longlong_t busy_donated_spurr      | Number of busy spurr cycles donated by a dedicated partition enabled for donation.                                                                                                                    |
| u_longlong_t idle_stolen_purr        | Number of idle cycles stolen by the hypervisor from a dedicated partition.                                                                                                                            |
| u_longlong_t idle_stolen_spurr       | Number of idle spurr cycles stolen by the hypervisor from a dedicated partition.                                                                                                                      |
| u_longlong_t busy_stolen_purr        | Number of busy cycles stolen by the hypervisor from a dedicated partition.                                                                                                                            |
| u_longlong_t busy_stolen_spurr       | Number of busy spurr cycles stolen by the hypervisor from a dedicated partition.                                                                                                                      |
| u_longlong_t shcpus_in_sys           | Number of physical processors allocated for shared processor use, across all shared processors pools.                                                                                                 |
| u_longlong_t max_pool_capacity       | Maximum processor capacity of shared processor pool to which this partition belongs.                                                                                                                  |
| u_longlong_t entitled_pool_capacity  | Entitled processor capacity of shared processor pool to which this partition belongs.                                                                                                                 |
| u_longlong_t pool_max_time           | The summation of maximum time (in nanoseconds) that might be used by the shared processor pool to which this partition belongs.                                                                       |
| u_longlong_t pool_busy_time          | The summation of busy (nonidle) time (in nanoseconds) accumulated across all partitions in the shared processor pool to which this partition belongs.                                                 |
| u_longlong_t pool_scaled_busy_time   | The summation of busy (nonidle) time in (nanoseconds) accumulated across all partitions in the shared processor pool to which this partition belongs. The time is against rated or nominal frequency. |
| u_longlong_t shcpu_tot_time          | The summation of total time (in nanoseconds) across all physical processors that are allocated to the shared processor pool (where the Pool ID equals 0) use across all shared processor pools.       |

| Item                                | Description                                                                                                                                                                                                  |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t shcpu_busy_time        | The summation of busy (nonidle) time (in nanoseconds) accumulated across all physical processors for shared processor pool (where the Pool ID equals 0) use across all shared processor pools.               |
| u_longlong_t shcpu_scaled_busy_time | The summation of scaled busy (nonidle) time (in nanoseconds) accumulated across all partitions in the shared processor pool to which this partition belongs. The time is against rated or nominal frequency. |
| int ams_pool_id                     | AMS pool ID of the pool the LPAR belongs to.                                                                                                                                                                 |
| int var_mem_weight                  | Variable memory capacity weight.                                                                                                                                                                             |
| u_longlong_t iome                   | I/O memory entitlement of the partition in bytes.                                                                                                                                                            |
| u_longlong_t pmem                   | Physical memory currently backing the partition's logical memory in bytes.                                                                                                                                   |
| u_longlong_t hpi                    | Number of hypervisor page-ins.                                                                                                                                                                               |
| u_longlong_t hpit                   | Time spent in hypervisor page-ins (in nanoseconds).                                                                                                                                                          |
| u_longlong_t hypv_pagesize          | Hypervisor page size in KB.                                                                                                                                                                                  |
| uint online_lcpus                   | Number of online logical processors.                                                                                                                                                                         |
| uint smt_thrds                      | Number of SMT threads.                                                                                                                                                                                       |
| uint power_save_mode                | Power save mode for the LPAR.                                                                                                                                                                                |
| ushort ame_version                  | AME version.                                                                                                                                                                                                 |
| u_longlong_t true_memory            | True memory size in 4 KB pages.                                                                                                                                                                              |
| u_longlong_t expanded_memory        | Expanded memory size in 4 KB pages.                                                                                                                                                                          |
| u_longlong_t target_memexp_factr    | Target memory expansion factor scaled by 100.                                                                                                                                                                |
| u_longlong_t current_memexp_factr   | Current memory expansion factor scaled by 100.                                                                                                                                                               |
| u_longlong_t target_cpool_size      | Target compressed pool size in bytes.                                                                                                                                                                        |
| u_longlong_t max_cpool_size         | Maximum size of compressed pool in bytes.                                                                                                                                                                    |
| u_longlong_t min_ucpool_size        | Minimum size of uncompressed pool in bytes.                                                                                                                                                                  |
| u_longlong_t ame_deficit_size       | Deficit memory size in bytes.                                                                                                                                                                                |
| u_longlong_t MemPoolSize            | The memory pool size of the pool to which the partition belongs in bytes.                                                                                                                                    |
| u_longlong_t IOMemEntInUse          | The I/O memory entitlement of the LPAR that is in use (in bytes).                                                                                                                                            |
| u_longlong_t IOMemEntFree           | Free I/O memory entitlement (in bytes).                                                                                                                                                                      |
| u_longlong_t IOHighWaterMark        | The high watermark of the I/O memory entitlement usage (in bytes).                                                                                                                                           |

**Note:** The fields IOMemEntInUse, IOMemEntFree, and IOHighWaterMark fields displays the actual values if the system is AMS enabled. Otherwise, it displays a 0. If AMS is enabled and displays a value of 0, it indicates the actual values. The **amepat** command can be used to know whether the system is AMS enabled.

The **perfstat\_partition\_type\_t** structure contains the following members:

| Item                           | Description                            |
|--------------------------------|----------------------------------------|
| unsigned:1 smt_capable         | OS supports SMT mode.                  |
| unsigned:1 smt_enabled         | SMT mode is on.                        |
| unsigned:1 lpar_capable        | OS supports logical partitioning.      |
| unsigned:1 lpar_enabled        | Logical partitioning is on.            |
| unsigned:1 shared_capable      | OS supports shared processor LPAR.     |
| unsigned:1 shared_enabled      | Partition runs in shared mode.         |
| unsigned:1 d1par_capable       | OS supports dynamic LPAR.              |
| unsigned:1 capped              | Partition is capped.                   |
| unsigned:1 kernel_is_64        | Kernel is 64 bits.                     |
| unsigned:1 pool_util_authority | Pool utilization data is available.    |
| unsigned:1 donate_capable      | Partition capable of donating cycles.  |
| unsigned:1 donate_enabled      | Partition enabled for donating cycles. |
| unsigned:1 power_save_mode     | Partition enabled for power savings.   |
| unsigned:1 ame_enabled         | Partition enabled for AME              |

The **perfstat\_value\_t** structure contains the following members:

| <b>Item</b>                       | <b>Description</b>  |
|-----------------------------------|---------------------|
| <code>u_longlong_t online</code>  | Online statistics.  |
| <code>u_longlong_t max</code>     | Maximum statistics. |
| <code>u_longlong_t min</code>     | Minimum statistics. |
| <code>u_longlong_t desired</code> | Desired statistics. |

The `perfstat_partition_config_t` structure contains the following members:

| <b>Item</b>                                  | <b>Description</b>                                                                    |
|----------------------------------------------|---------------------------------------------------------------------------------------|
| <code>u_longlong_t version</code>            | Version number of data structure.                                                     |
| <code>char partitionname[64]</code>          | Partition name.                                                                       |
| <code>char nodename[64]</code>               | Node name.                                                                            |
| <code>perfstat_partition_type_t conf</code>  | Partition properties.                                                                 |
| <code>uint partitionnum</code>               | Partition number.                                                                     |
| <code>uint groupid</code>                    | Group ID.                                                                             |
| <code>char processorFamily[64]</code>        | Processor type.                                                                       |
| <code>char processorModel[64]</code>         | Processor model.                                                                      |
| <code>char machineID[64]</code>              | Machine ID.                                                                           |
| <code>double processorMHz</code>             | Processor clock speed in MHz                                                          |
| <code>perfstat_value_t numProcessors</code>  | Number of configured physical processors in frame.                                    |
| <code>char OSName[64]</code>                 | Name of operating system.                                                             |
| <code>char OSVersion[64]</code>              | Version of operating system.                                                          |
| <code>char OSBuild[64]</code>                | Build of operating system.                                                            |
| <code>uint lcpus</code>                      | Number of logical CPUs.                                                               |
| <code>uint smtthreads</code>                 | Number of SMT threads.                                                                |
| <code>uint drives</code>                     | Total number of drives.                                                               |
| <code>uint nw_adapters</code>                | Total number of network adapters.                                                     |
| <code>perfstat_value_t cpucap</code>         | Min, max, and online CPU capacity.                                                    |
| <code>uint cpucap_weightage</code>           | Variable processor capacity weightage.                                                |
| <code>int entitled_proc_capacity</code>      | Number of processor units this partition is entitled to receive.                      |
| <code>perfstat_value_t vcpus</code>          | Min, max, and online virtual CPUs.                                                    |
| <code>uint processor_poolid</code>           | Shared pool ID of physical processors, to which this partition belongs.               |
| <code>uint activecpusinpool</code>           | Count of physical CPUs in the shared processor pool, to which this partition belongs. |
| <code>uint cpupool_weightage</code>          | Pool weightage.                                                                       |
| <code>uint sharedpcpu</code>                 | Number of physical processors allocated for shared processor use.                     |
| <code>uint maxpoolcap</code>                 | Maximum processor capacity of partition's pool.                                       |
| <code>uint entpoolcap</code>                 | Entitled processor capacity of partition's pool.                                      |
| <code>perfstat_value_t mem</code>            | Min, max, and online memory.                                                          |
| <code>uint mem_weightage</code>              | Variable memory capacity weightage.                                                   |
| <code>u_longlong_t totiomement</code>        | I/O memory entitlement of the partition in bytes.                                     |
| <code>int mempoolid</code>                   | AMS pool ID of the pool the LPAR belongs to.                                          |
| <code>u_longlong_t hyperpgsize</code>        | Hypervisor page size in KB.                                                           |
| <code>perfstat_value_t exp_mem</code>        | Min, max, and online expanded memory.                                                 |
| <code>u_longlong_t targetmemexpfactor</code> | Target memory expansion factor scaled by 100.                                         |
| <code>u_longlong_t targetmemexpsize</code>   | Expanded memory size in MB.                                                           |
| <code>uint subprocessormode</code>           | Sub processor mode for the partition.                                                 |

The `perfstat_wpar_total_t` structure contains the following members:

| Item                          | Description                                                                                                                             |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| char name[MAXCORRALNAMELEN+1] | Name of the workload partition                                                                                                          |
| perfstat_wpar_type_t type     | Set of bits describing the WPAR                                                                                                         |
| cid_t wpar_id                 | workload partition identifier.                                                                                                          |
| uint online_cpus              | Number of virtual processors in partition resource set (reset) or number of virtual processors that are online in the Global partition. |
| int cpu_limit                 | Processor limit. This value is represented in percentage multiplied by 100. For example, if the limit is 50%, the value is 5000.        |
| int mem_limit                 | Memory limit. This value is represented in percentage multiplied by 100. For example, if the limit is 50%, the value is 5000.           |
| u_longlong_t online_memory    | Amount of memory that is online in the Global partition.                                                                                |
| int entitled_proc_capacity    | Number of processor units that the partition is entitled to receive.                                                                    |

The **perfstat\_wpar\_type\_t** structure contains the following members:

| Item   | Description |
|--------|-------------|
| uint   | w           |
| struct | b           |

The **b** structure contains the following members:

| Item                  | Description                                          |
|-----------------------|------------------------------------------------------|
| unsigned:1 app_wpar   | WPAR application.                                    |
| unsigned:1 cpu_rset   | WPAR restricted to processor resource set.           |
| unsigned:1 cpu_xrset  | WPAR restricted to processor exclusive resource set. |
| unsigned:1 cpu_limits | Processor resource limits enforced.                  |
| unsigned:1 mem_limits | Memory resource limits enforced.                     |
| unsigned:1 spare      | Reserved for future usage.                           |

The **perfstat\_disk\_t** structure contains the following members:

| Item                                | Description                                                                                         |
|-------------------------------------|-----------------------------------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]        | Name of the disk.                                                                                   |
| char description[IDENTIFIER_LENGTH] | Disk description (from ODM).                                                                        |
| char vgname[IDENTIFIER_LENGTH]      | Volume group name (from ODM).                                                                       |
| u_longlong_t size                   | Size of the disk (in MB).                                                                           |
| u_longlong_t free                   | Free portion of the disk (in MB).                                                                   |
| u_longlong_t bsize                  | Disk block size (in bytes).                                                                         |
| u_longlong_t __rxfers               | Number of transfers from disk.                                                                      |
| u_longlong_t xfers                  | Number of transfers to/from disk.                                                                   |
| u_longlong_t wblk                   | Number of blocks written to disk.                                                                   |
| u_longlong_t rblk                   | Number of blocks read from disk.                                                                    |
| u_longlong_t time                   | Amount of time (in clock ticks) disk is active.                                                     |
| char adapter[IDENTIFIER_LENGTH]     | Disk adapter name.                                                                                  |
| uint paths_count                    | Number of paths defined to the disk.                                                                |
| u_longlong_t qdepth                 | Instantaneous "service" queue depth (number of requests sent to disk and not completed yet).        |
| u_longlong_t q_full                 | "Service" queue full occurrence count (number of times the disk is not accepting any more request). |
| u_longlong_t q_sampled              | Accumulated sampled "service" queue depth.                                                          |
| u_longlong_t rserv                  | Read service time.                                                                                  |
| u_longlong_t rtimeout               | Number of read request timeout.                                                                     |
| u_longlong_t rfailed                | Number of failed read requests.                                                                     |
| u_longlong_t min_rserv              | Minimum read service time.                                                                          |
| u_longlong_t max_rserv              | Maximum read service time.                                                                          |
| u_longlong_t wserv                  | Write service time.                                                                                 |
| u_longlong_t wtimeout               | Number of write request timeout.                                                                    |
| su_longlong_t wfailing              | Number of failed write requests.                                                                    |
| u_longlong_t min_wserv              | Minimum write service time.                                                                         |

| Item                     | Description                                                                     |
|--------------------------|---------------------------------------------------------------------------------|
| u_longlong_t max_wserv   | Maximum write service time.                                                     |
| u_longlong_t wq_depth    | Instantaneous wait queue depth (number of requests waiting to be sent to disk). |
| u_longlong_t wq_sampled  | Accumulated sampled <b>wq_depth</b> .                                           |
| u_longlong_t wq_time     | Accumulated wait queueing time.                                                 |
| u_longlong_t wq_min_time | Minimum wait queueing time.                                                     |
| u_longlong_t wq_max_time | Maximum wait queueing time.                                                     |
| cid_t wpar_id            | WPAR identifier.                                                                |

The size, free, vgname, adapter, and description members of the **perfstat\_disk\_t** structure are stored in the information cache. They can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_DISK)`
- `perfstat_partial_reset("disk name", FLUSH_DISK)`
- `perfstat_partial_reset(NULL, FLUSH_DISKADAPTER)`
- `perfstat_partial_reset("adapter name of this disk", FLUSH_DISKADAPTER)`

The **perfstat\_disk\_total\_t** structure contains the following members:

| Item                     | Description                                                                     |
|--------------------------|---------------------------------------------------------------------------------|
| int number               | Total number of disks.                                                          |
| u_longlong_t size        | Total size of all disks (in MB).                                                |
| u_longlong_t free        | Free portion of all disks (in MB).                                              |
| u_longlong_t __rxfers    | Total number of transfers from disk.                                            |
| u_longlong_t xfers       | Total number of transfers to/from disk.                                         |
| u_longlong_t wblk        | 512 bytes blocks written to all disks.                                          |
| u_longlong_t rblk        | 512 bytes blocks read from all disks.                                           |
| u_longlong_t time        | Amount of time (in clock ticks) disks are active.                               |
| cid_t wpar_id            | WPAR identifier.                                                                |
| u_longlong_t rserv;      | Average read or receive service time.                                           |
| u_longlong_t min_rserv   | Min read or receive service time.                                               |
| u_longlong_t max_rserv   | Max read or receive service time.                                               |
| u_longlong_t rtimeout    | Number of read request timeouts.                                                |
| u_longlong_t rfailed     | Number of failed read requests.                                                 |
| u_longlong_t wserv       | Average write or send service time.                                             |
| u_longlong_t min_wserv   | Min write or send service time.                                                 |
| u_longlong_t max_wserv   | Max write or send service time.                                                 |
| u_longlong_t wtimeout    | Number of write request timeouts.                                               |
| u_longlong_t wfailed     | Number of failed write requests.                                                |
| u_longlong_t wq_depth    | Instantaneous wait queue depth (number of requests waiting to be sent to disk). |
| u_longlong_t wq_time     | Accumulated wait queueing time.                                                 |
| u_longlong_t wq_min_time | Min wait queueing time.                                                         |
| u_longlong_t wq_max_time | Max wait queueing time.                                                         |

The size and free members of the **perfstat\_disk\_total\_t** structure are stored in the information cache. They can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_DISK)`
- `perfstat_partial_reset("disk name", FLUSH_DISK)`
- `perfstat_partial_reset(NULL, FLUSH_DISKADAPTER)`
- `perfstat_partial_reset("adapter name of this disk", FLUSH_DISKADAPTER)`

The **perfstat\_diskadapter\_t** structure contains the following members:

| Item                                | Description                                                                                                           |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| adapter_type                        | 0        SCSI, SAS, other legacy adapter types<br>1        Virtual SCSI/SAS Adapter<br>2        Fiber Channel Adapter |
| char name[IDENTIFIER_LENGTH]        | Name of the adapter (from ODM).                                                                                       |
| char description[IDENTIFIER_LENGTH] | Adapter description (from ODM).                                                                                       |
| dk_bsize                            | Number of Bytes in a block for this disk.                                                                             |
| dk_rxfers                           | Number of transfers from disk.                                                                                        |
| dk_rserv                            | Read or receive service time.                                                                                         |
| dk_wserv                            | Write or send service time.                                                                                           |
| int number                          | Number of disks connected to adapter.                                                                                 |
| u_longlong_t size                   | Total size of all disks (in MB).                                                                                      |
| u_longlong_t free                   | Free portion of all disks (in MB).                                                                                    |
| u_longlong_t __rxfers               | Total number of reads via adapter.                                                                                    |
| u_longlong_t xfers                  | Total number of transfers to/from disk.                                                                               |
| u_longlong_t wblk                   | 512 bytes blocks written via adapter.                                                                                 |
| u_longlong_t rblk                   | 512 bytes blocks read via adapter.                                                                                    |
| u_longlong_t time                   | Amount of time (in clock ticks) disks are active.                                                                     |

The list of the disk adapters and the size, free, and description members of the **perfstat\_diskadapter\_t** structure are stored in the information cache. They can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_DISKADAPTER)`
- `perfstat_partial_reset("diskadapter name", FLUSH_DISKADAPTER)`
- `perfstat_partial_reset(NULL, FLUSH_DISK)`
- `perfstat_partial_reset("disk linked to this adapter", FLUSH_DISK)`

The **perfstat\_diskpath\_t** structure contains the following members:

| Item                             | Description                                                                                         |
|----------------------------------|-----------------------------------------------------------------------------------------------------|
| char name [IDENTIFIER_LENGTH]    | Name of the path.                                                                                   |
| u_longlong_t __rxfers            | Number of reads completed through the path.                                                         |
| u_longlong_t xfers               | Total number of transfers through the path.                                                         |
| u_longlong_t wblk                | 512 bytes blocks written through the path.                                                          |
| u_longlong_t rblk                | 512 bytes blocks read through the path.                                                             |
| u_longlong_t time                | Amount of time (in clock ticks) path is active.                                                     |
| char adapter [IDENTIFIER_LENGTH] | Name of the adapter.                                                                                |
| u_longlong_t q_full              | "Service" queue full occurrence count (number of times the disk is not accepting any more request). |
| u_longlong_t q_sampled           | Accumulated sampled "service" queue depth.                                                          |
| u_longlong_t rserv               | Read service time.                                                                                  |
| u_longlong_t rtimeout            | Number of read request timeout.                                                                     |
| u_longlong_t rfailed             | Number of failed read requests.                                                                     |
| u_longlong_t min_rserv           | Minimum read service time.                                                                          |
| u_longlong_t max_rserv           | Maximum read service time.                                                                          |
| u_longlong_t wserv               | Write service time.                                                                                 |
| u_longlong_t wtimeout            | Number of write request timeout.                                                                    |
| u_longlong_t wfailed             | Number of failed write requests.                                                                    |
| u_longlong_t min_wserv           | Minimum write service time.                                                                         |
| u_longlong_t max_wserv           | Maximum write service time.                                                                         |
| u_longlong_t wq_depth            | Instantaneous wait queue depth (number of requests waiting to be sent to disk).                     |
| u_longlong_t wq_sampled          | Accumulated sampled <b>wq_depth</b> .                                                               |
| u_longlong_t wq_time             | Accumulated wait queuing time.                                                                      |

| Item                                  | Description                |
|---------------------------------------|----------------------------|
| <code>u_longlong_t wq_min_time</code> | Minimum wait queuing time. |
| <code>u_longlong_t wq_max_time</code> | Maximum wait queuing time. |

The adapter member of the `perfstat_diskpath_t` structure is stored in the information cache. It can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_DISKPATH)`
- `perfstat_partial_reset("diskpath name", FLUSH_DISKPATH)`
- `perfstat_partial_reset(NULL, FLUSH_DISKADAPTER)`
- `perfstat_partial_reset("diskadapter name of this diskpath", FLUSH_DISKADAPTER)`
- `perfstat_partial_reset(NULL, FLUSH_DISK)`
- `perfstat_partial_reset("disk pointed by this path", FLUSH_DISK)`

The `perfstat_memory_total_t` structure contains the following members:

| Item                                       | Description                                                                                                                                                                                                                                          |
|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>u_longlong_t virt_total</code>       | Total virtual memory (in 4 KB pages).                                                                                                                                                                                                                |
| <code>u_longlong_t real_total</code>       | Total real memory (in 4 KB pages).                                                                                                                                                                                                                   |
| <code>u_longlong_t real_free</code>        | Free real memory (in 4 KB pages).                                                                                                                                                                                                                    |
| <code>u_longlong_t real_pinned</code>      | Real memory which is pinned (in 4 KB pages).                                                                                                                                                                                                         |
| <code>u_longlong_t real_inuse</code>       | Real memory which is in use (in 4 KB pages).                                                                                                                                                                                                         |
| <code>u_longlong_t pgbad</code>            | Number of bad pages.                                                                                                                                                                                                                                 |
| <code>u_longlong_t pgexct</code>           | Number of page faults.                                                                                                                                                                                                                               |
| <code>u_longlong_t pgins</code>            | Number of pages paged in.                                                                                                                                                                                                                            |
| <code>u_longlong_t pgouts</code>           | Number of pages paged out.                                                                                                                                                                                                                           |
| <code>u_longlong_t pgspins</code>          | Number of page ins from paging space.                                                                                                                                                                                                                |
| <code>u_longlong_t pgspouts</code>         | Number of page outs from paging space.                                                                                                                                                                                                               |
| <code>u_longlong_t scans</code>            | Number of page scans by clock.                                                                                                                                                                                                                       |
| <code>u_longlong_t cycles</code>           | Number of page replacement cycles.                                                                                                                                                                                                                   |
| <code>u_longlong_t pgsteals</code>         | Number of page steals.                                                                                                                                                                                                                               |
| <code>u_longlong_t numperm</code>          | Number of frames used for files (in 4 KB pages).                                                                                                                                                                                                     |
| <code>u_longlong_t pgsp_total</code>       | Total paging space (in 4 KB pages).                                                                                                                                                                                                                  |
| <code>u_longlong_t pgsp_free</code>        | Free paging space (in 4 KB pages).                                                                                                                                                                                                                   |
| <code>u_longlong_t pgsp_rsvd</code>        | Reserved paging space (in 4 KB pages).                                                                                                                                                                                                               |
| <code>u_longlong_t real_system</code>      | Real memory used by system segments (in 4 KB pages). This value is the sum of all the used pages in segment marked for system usage. Because segment classifications are not always guaranteed to be accurate, this number is only an approximation. |
| <code>u_longlong_t real_user</code>        | Real memory used by non-system segments (in 4 KB pages). This is the sum of all pages used in segments not marked for system usage. Because segment classifications are not always guaranteed to be accurate, this number is only an approximation.  |
| <code>u_longlong_t real_process</code>     | Real memory used by process segments (in 4 KB pages). This is <code>real_total-real_free-numperm-real_system</code> . Because <code>real_system</code> is an approximation, this number is as well.                                                  |
| <code>u_longlong_t virt_active</code>      | Active virtual pages (avm column in vmstat output). Virtual pages are considered active if they have been accessed.                                                                                                                                  |
| <code>u_longlong_t iome</code>             | I/O memory entitlement of the partition in bytes.                                                                                                                                                                                                    |
| <code>u_longlong_t iomu</code>             | I/O memory entitlement of the partition in use in bytes.                                                                                                                                                                                             |
| <code>u_longlong_t iohwm</code>            | High water mark of I/O memory entitlement used in bytes.                                                                                                                                                                                             |
| <code>u_longlong_t pmem</code>             | Amount of physical memory currently backing partition's logical memory in bytes.                                                                                                                                                                     |
| <code>u_longlong_t comprsd_total</code>    | Total numbers of pages in compressed pool (in 4 KB pages).                                                                                                                                                                                           |
| <code>u_longlong_t comprsd_wseg_pgs</code> | Number of compressed working storage pages.                                                                                                                                                                                                          |
| <code>u_longlong_t cpgins</code>           | Number of page ins to compressed pool.                                                                                                                                                                                                               |
| <code>u_longlong_t cpgouts</code>          | Number of page outs from compressed pool.                                                                                                                                                                                                            |

| <b>Item</b>                    | <b>Description</b>                                              |
|--------------------------------|-----------------------------------------------------------------|
| u_longlong_t true_size         | True memory size in 4 KB pages.                                 |
| u_longlong_t expanded_memory   | Expanded memory size in 4 KB pages.                             |
| u_longlong_t comprsd_wseg_size | Total size of the compressed working storage pages in the pool. |
| u_longlong_t target_cpool_size | Target compressed pool size in bytes.                           |
| u_longlong_t max_cpool_size    | Maximum size of compressed pool in bytes.                       |
| u_longlong_t min_ucpool_size   | Minimum size of uncompressed pool in bytes.                     |
| u_longlong_t cpool_size        | Compressed pool size in bytes.                                  |
| u_longlong_t ucpool_size       | Uncompressed pool size in bytes.                                |
| u_longlong_t cpool_inuse       | Compressed pool used in bytes.                                  |
| u_longlong_t ucpool_inuse      | Uncompressed pool used in bytes.                                |

The **perfstat\_memory\_total\_wpar\_t** structure contains the following members:

| <b>Item</b>                    | <b>Description</b>                                                                    |
|--------------------------------|---------------------------------------------------------------------------------------|
| u_longlong_t real_total        | Global total real memory (in 4 KB pages).                                             |
| u_longlong_t real_free         | Global free real memory (in 4 KB pages).                                              |
| u_longlong_t real_pinned       | Real memory that is pinned (in 4 KB pages).                                           |
| u_longlong_t real_inuse        | Real memory that is in use (in 4 KB pages).                                           |
| u_longlong_t pgfaults          | Number of page faults.                                                                |
| u_longlong_t pgins             | Number of pages paged in.                                                             |
| u_longlong_t pgouts            | Number of pages paged out.                                                            |
| u_longlong_t pgspins           | Number of page-ins from paging space.                                                 |
| u_longlong_t pgspouts          | Number of page-outs from paging space.                                                |
| u_longlong_t scans             | Number of page-scans by clock.                                                        |
| u_longlong_t pgsteals          | Number of page-steals.                                                                |
| u_longlong_t numperm           | Number of frames used for files (in 4 KB pages).                                      |
| u_longlong_t virt_active       | Active virtual pages. Virtual pages are considered active if they have been accessed. |
| u_longlong_t comprsd_total     | Total numbers of pages in compressed pool (in 4 KB pages).                            |
| u_longlong_t comprsd_wseg_pgs  | Number of compressed working storage pages.                                           |
| u_longlong_t cpugins           | Number of page ins to compressed pool.                                                |
| u_longlong_t cpayouts          | Number of page outs from compressed pool.                                             |
| u_longlong_t comprsd_wseg_size | Total size of the compressed working storage pages in the pool.                       |
| u_longlong_t ucpool_size       | Uncompressed pool size in bytes.                                                      |

The **perfstat\_tape\_t** structure contains the following members:

| <b>Item</b>                         | <b>Description</b>                     |
|-------------------------------------|----------------------------------------|
| char name[IDENTIFIER_LENGTH]        | Name of the tape.                      |
| char description[IDENTIFIER_LENGTH] | Tape description (from ODM).           |
| u_longlong_t size                   | Size of the tape (in MB).              |
| u_longlong_t free                   | Free portion of the tape (in MB).      |
| u_longlong_t bsize                  | Tape block size (in bytes).            |
| u_longlong_t xfers                  | Number of transfers to/from tape.      |
| u_longlong_t rxfers                 | Number of read transfers to/from tape. |
| u_longlong_t wblk                   | Number of blocks written to tape.      |
| u_longlong_t rblk                   | Number of blocks read from tape.       |
| u_longlong_t time                   | Amount of time tape is active.         |
| char adapter[IDENTIFIER_LENGTH]     | Tape adapter name.                     |
| uint paths_count                    | Number of paths to this tape.          |
| u_longlong_t rserv                  | Read or receive service time.          |
| u_longlong_t rtimeout               | Number of read request timeout.        |
| u_longlong_t rfailed                | Number of failed read requests.        |
| u_longlong_t min_rserv              | Minimum read or receive service time.  |
| u_longlong_t max_rserv              | Maximum read or receive service time.  |
| u_longlong_t wserv                  | Write or send service time.            |
| u_longlong_t wtimeout               | Number of write request timeout.       |

| Item                                | Description                         |
|-------------------------------------|-------------------------------------|
| <code>u_longlong_t wfailed</code>   | Number of failed write requests.    |
| <code>u_longlong_t min_wserv</code> | Minimum write or send service time. |
| <code>u_longlong_t max_wserv</code> | Maximum write or send service time. |

The `perfstat_tape_total_t` structure contains the following members:

| Item                             | Description                             |
|----------------------------------|-----------------------------------------|
| <code>int number</code>          | Total number of tapes.                  |
| <code>u_longlong_t size</code>   | Total size of all tapes (in MB).        |
| <code>u_longlong_t free</code>   | Free portion of all tapes (in MB).      |
| <code>u_longlong_t rxfers</code> | Number of read transfers to/from tape.  |
| <code>u_longlong_t xfers</code>  | Total number of transfers to/from tape. |
| <code>u_longlong_t wbblk</code>  | 512 bytes blocks written to all tapes.  |
| <code>u_longlong_t rbblk</code>  | 512 bytes blocks read from all tapes.   |
| <code>u_longlong_t time</code>   | Total time the tapes are active.        |

The `perfstat_memory_page_t` structure contains the following members:

| psize_t                                     | psize                          | page size in bytes                                                                                                                                                                                                                      |
|---------------------------------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>u_longlong_t real_total</code>        | <code>real_total</code>        | Number of real memory frames of this page size.                                                                                                                                                                                         |
| <code>u_longlong_t real_free</code>         | <code>real_free</code>         | Number of pages on free list.                                                                                                                                                                                                           |
| <code>u_longlong_t real_pinned</code>       | <code>real_pinned</code>       | Number of pages pinned.                                                                                                                                                                                                                 |
| <code>u_longlong_t real_inuse</code>        | <code>real_inuse</code>        | Number of pages in use.                                                                                                                                                                                                                 |
| <code>u_longlong_t pgexct</code>            | <code>pgexct</code>            | Number of page faults.                                                                                                                                                                                                                  |
| <code>u_longlong_t pgins</code>             | <code>pgins</code>             | Number of pages paged in.                                                                                                                                                                                                               |
| <code>u_longlong_t pouts</code>             | <code>pouts</code>             | Number of pages paged out.                                                                                                                                                                                                              |
| <code>u_longlong_t pgspins</code>           | <code>pgspins</code>           | Number of page ins from paging space.                                                                                                                                                                                                   |
| <code>u_longlong_t pgspouts</code>          | <code>pgspouts</code>          | Number of page outs from paging space.                                                                                                                                                                                                  |
| <code>u_longlong_t scans</code>             | <code>scans</code>             | Number of page scans by clock.                                                                                                                                                                                                          |
| <code>u_longlong_t cycles</code>            | <code>cycles</code>            | Number of page replacement cycles.                                                                                                                                                                                                      |
| <code>u_longlong_t pgsteals</code>          | <code>pgsteals</code>          | Number of page steals.                                                                                                                                                                                                                  |
| <code>u_longlong_t numperm</code>           | <code>numperm</code>           | Number of frames used for files.                                                                                                                                                                                                        |
| <code>u_longlong_t numpgsp</code>           | <code>numpgsp</code>           | Number of pages with allocated paging space.                                                                                                                                                                                            |
| <code>u_longlong_t real_system</code>       | <code>real_system</code>       | Number of pages used by system segments. This is the sum of all the used pages in segment marked for system usage. Because segment classifications are not always guaranteed to be accurate, This number is only an approximation.      |
| <code>u_longlong_t real_user</code>         |                                | Number of pages used by non-system segments. This is the sum of all pages used in segments not marked for system usage. Because segment classifications are not always guaranteed to be accurate, This number is only an approximation. |
| <code>u_longlong_t real_process</code>      |                                | Number of pages used by process segments. This is <code>real_total - real_free - numperm - real_system</code> . Because <code>real_system</code> is an approximation, this number is too.                                               |
| <code>u_longlong_t virt_active</code>       |                                | Active virtual pages. Virtual pages are considered active if they have been accessed.                                                                                                                                                   |
| <code>u_longlong_t comprsd_total</code>     | <code>comprsd_total</code>     | Number of pages of this size compressed.                                                                                                                                                                                                |
| <code>u_longlong_t comprsd_wseg_pgs</code>  | <code>comprsd_wseg_pgs</code>  | Number of compressed working storage pages.                                                                                                                                                                                             |
| <code>u_longlong_t cpgins</code>            | <code>cpgins</code>            | Number of page ins of this page size to compressed pool.                                                                                                                                                                                |
| <code>u_longlong_t cpout</code>             | <code>cpout</code>             | Number of page outs of this page size from compressed pool.                                                                                                                                                                             |
| <code>u_longlong_t cpool_inuse</code>       | <code>cpool_inuse</code>       | Compressed size (in MB) of this page size in compressed pool.                                                                                                                                                                           |
| <code>u_longlong_t ucpool_size</code>       | <code>ucpool_size</code>       | Uncompressed pool size in MB of this page size.                                                                                                                                                                                         |
| <code>u_longlong_t comprsd_wseg_size</code> | <code>comprsd_wseg_size</code> | Total size of the compressed working storage pages in the pool.                                                                                                                                                                         |

The `perfstat_memory_page_wpar_t` structure contains the following members:

|                |                   |                                                                 |
|----------------|-------------------|-----------------------------------------------------------------|
| <b>psize_t</b> | <b>psize</b>      | <b>page size in bytes</b>                                       |
| u_longlong_t   | real_total        | Number of real memory frames of this page size.                 |
| u_longlong_t   | real_pinned       | Number of pages pinned.                                         |
| u_longlong_t   | real_inuse        | Number of pages in use.                                         |
| u_longlong_t   | pgexct            | Number of page faults.                                          |
| u_longlong_t   | pgins             | Number of pages paged in.                                       |
| u_longlong_t   | pouts             | Number of pages paged out.                                      |
| u_longlong_t   | pgspins           | Number of page ins from paging space.                           |
| u_longlong_t   | pgspouts          | Number of page outs from paging space.                          |
| u_longlong_t   | scans             | Number of page scans by clock.                                  |
| u_longlong_t   | pgsteals          | Number of page steals.                                          |
| u_longlong_t   | comprsd_total     | Number of pages of this size compressed.                        |
| u_longlong_t   | comprsd_wseg_pgs  | Number of compressed working storage pages.                     |
| u_longlong_t   | cpgins            | Number of page ins of this page size to compressed pool.        |
| u_longlong_t   | cpgouts           | Number of page outs of this page size from compressed pool.     |
| u_longlong_t   | cpool_inuse       | Compressed size (in MB) of this page size in compressed pool.   |
| u_longlong_t   | ucpool_size       | Uncompressed pool size in MB of this page size.                 |
| u_longlong_t   | comprsd_wseg_size | Total size of the compressed working storage pages in the pool. |

The **perfstat\_process\_t** structure contains the following members:

| <b>Item</b>                       | <b>Description</b>                                                                                                                                                                                                             |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t version              | Version number of data structure.                                                                                                                                                                                              |
| u_longlong_t pid                  | Process ID.                                                                                                                                                                                                                    |
| char proc_name[64]                | Name of the process.                                                                                                                                                                                                           |
| int proc_priority                 | Process priority.                                                                                                                                                                                                              |
| u_longlong_t num_threads          | Thread count.                                                                                                                                                                                                                  |
| u_longlong_t proc_uid             | Owner information.                                                                                                                                                                                                             |
| u_longlong_t proc_classid         | WLM class name.                                                                                                                                                                                                                |
| u_longlong_t proc_size            | Virtual size of the process (exclusive usage, leaving all shared library text & shared file pages, shared memory, and memory mapped).                                                                                          |
| u_longlong_t proc_real_mem_data   | Real memory used for data in KB.                                                                                                                                                                                               |
| u_longlong_t proc_real_mem_text   | Real memory used for text in KB.                                                                                                                                                                                               |
| u_longlong_t proc_virt_mem_data   | Virtual memory used for data in KB.                                                                                                                                                                                            |
| u_longlong_t proc_virt_mem_text   | Virtual memory used for text in KB.                                                                                                                                                                                            |
| u_longlong_t shared_lib_data_size | Data size from shared library in KB.                                                                                                                                                                                           |
| u_longlong_t heap_size            | Heap size in KB.                                                                                                                                                                                                               |
| u_longlong_t real_inuse           | The Real memory (in KB) in use by the process including all kind of segments (excluding system segments). This includes text, data, shared library text, shared library data, file pages, shared memory, and memory mapped.    |
| u_longlong_t virt_inuse           | The virtual memory (in KB) in use by the process including all kind of segments (excluding system segments). This includes text, data, shared library text, shared library data, file pages, shared memory, and memory mapped. |
| u_longlong_t pinned               | Pinned memory (in KB) for this process inclusive of all segments.                                                                                                                                                              |
| u_longlong_t pgsp_inuse           | Paging space used (in KB) inclusive of all segments.                                                                                                                                                                           |
| u_longlong_t filepages            | File pages used (in KB) including shared pages.                                                                                                                                                                                |
| u_longlong_t real_inuse_map       | Real memory used (in KB) for shared memory and memory mapped regions                                                                                                                                                           |
| u_longlong_t virt_inuse_map       | Virtual memory used (in KB) for shared memory and memory mapped regions.                                                                                                                                                       |
| u_longlong_t pinned_inuse_map     | Pinned memory used (in KB) for shared memory and memory mapped regions.                                                                                                                                                        |
| double ucpu_time                  | User mode CPU time is in percentage or milliseconds based on, whether it is filled by perfstat_process_util or perfstat_process respectively.                                                                                  |
| double scpu_time                  | System mode CPU time is in percentage or milliseconds based on, whether it is filled by perfstat_process_util or perfstat_process respectively.                                                                                |
| u_longlong_t last_timebase        | Timebase counter.                                                                                                                                                                                                              |

| Item                  | Description              |
|-----------------------|--------------------------|
| u_longlong_t inBytes  | Bytes written to disk.   |
| u_longlong_t outBytes | Bytes read from disk.    |
| u_longlong_t inOps    | In operations from disk. |
| u_longlong_t outOps   | Out operations from disk |

The **perfstat\_netinterface\_t** structure contains the following members

| Item                                | Description                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]        | Name of the interface.                                                                                         |
| char description[IDENTIFIER_LENGTH] | Interface description (from ODM, similar to <b>lscfg</b> output).                                              |
| uchar type                          | Ethernet, token ring, and so on. Interpretation can be done using the <b>/usr/include/net/if_types.h</b> file. |
| u_longlong_t mtu                    | Network frame size.                                                                                            |
| u_longlong_t ipackets               | Number of packets received on interface.                                                                       |
| u_longlong_t ibytes                 | Number of bytes received on interface.                                                                         |
| u_longlong_t ierrors                | Number of input errors on interface.                                                                           |
| u_longlong_t opackets               | Number of packets sent on interface.                                                                           |
| u_longlong_t obytes                 | Number of bytes sent on interface.                                                                             |
| u_longlong_t oerrors                | Number of output errors on interface.                                                                          |
| u_longlong_t collisions             | Number of collisions on <b>csma</b> interface.                                                                 |
| u_longlong_t bitrate                | Adapter rating in bit per second.                                                                              |
| u_longlong_t if_iqdrops             | Dropped on input, this interface.                                                                              |
| u_longlong_t if_arpdrops            | Dropped because no arp response.                                                                               |

The **perfstat\_logicalvolume\_t** structure contains the following members:

| Item                                  | Description                                                               |
|---------------------------------------|---------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]          | Logical volume name.                                                      |
| char vname[IDENTIFIER_LENGTH]         | Volume group name.                                                        |
| u_longlong_t open_close               | LVM_QLVOOPEN, and so on. For more information, see the <b>lvm.h</b> file. |
| u_longlong_t state                    | LVM_UNDEF, and so on. For more information, see the <b>lvm.h</b> file.    |
| u_longlong_t mirror_policy            | LVM_PARALLEL, and so on. For more information, see the <b>lvm.h</b> file. |
| u_longlong_t mirror_write_consistency | LVM_CONSIST, and so on. For more information, see the <b>lvm.h</b> file.  |
| u_longlong_t write_verify             | LVM_VERIFY, and so on. For more information, see the <b>lvm.h</b> file.   |
| u_longlong_t ppsize                   | Physical partition size in MB.                                            |
| u_longlong_t logical_partitions       | Total number of logical partitions configured for this logical volume.    |
| ushort mirrors                        | Number of physical mirrors for each logical partition.                    |
| u_longlong_t iocnt                    | Number of read and write requests.                                        |
| u_longlong_t kbreads                  | Number of kilobytes read.                                                 |
| u_longlong_t kbwrites                 | Number of kilobytes written.                                              |
| u_longlong_t if_iqdrops               | Dropped on input, this interface.                                         |
| u_longlong_t if_arpdrops              | Dropped because no arp response.                                          |

The logical volume statistics collection must be enabled by using the following call:

```
perfstat_config(PERFSTAT_ENABLE | PERFSTAT_LV, NULL)
```

The logical volume statistics collection must be disabled after collecting the data by using the following call:

```
perfstat_config(PERFSTAT_DISABLE | PERFSTAT_LV, NULL)
```

The **perfstat\_volumegroup\_t** structure contains the following members:

| <b>Item</b>                         | <b>Description</b>                                                                                                                                                               |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]        | Volume group name.                                                                                                                                                               |
| u_longlong_t total_disks            | Number of physical volumes in the volume group.                                                                                                                                  |
| u_longlong_t active_disks           | Number of active physical volumes in the volume group.                                                                                                                           |
| u_longlong_t total_logical_volumes  | Number of logical volumes in the volume group.                                                                                                                                   |
| u_longlong_t opened_logical_volumes | Number of logical volumes opened in the volume group.                                                                                                                            |
| u_longlong_t iocnt                  | Number of read and write requests.                                                                                                                                               |
| u_longlong_t kbreads                | Number of kilobytes read.                                                                                                                                                        |
| u_longlong_t kbwrites               | Number of kilobytes written.                                                                                                                                                     |
| unsigned variedState                | Volume Group is Available or not <ul style="list-style-type: none"> <li>• 0 = Available which implies varied ON</li> <li>• 1 = Not Available which implies varied OFF</li> </ul> |

The volume group statistics collection must be enabled by using the following call:

```
perfstat_config(PERFSTAT_ENABLE | PERFSTAT_LV, NULL)
```

The volume groups statistics collection must be disabled after collecting the data by using the following call:

```
perfstat_config(PERFSTAT_DISABLE | PERFSTAT_LV, NULL)
```

The description member of the **perfstat\_netinterface\_t** structure is stored in the information cache. It can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_NETINTERFACE)`
- `perfstat_partial_reset("netinterface name", FLUSH_NETINTERFACE)`

The **perfstat\_netinterface\_total\_t** structure contains the following members:

| <b>Item</b>             | <b>Description</b>                             |
|-------------------------|------------------------------------------------|
| int number              | Number of network interfaces.                  |
| u_longlong_t ipackets   | Number of packets received on interface.       |
| u_longlong_t ibytes     | Number of bytes received on interface.         |
| u_longlong_t ierrors    | Number of input errors on interface.           |
| u_longlong_t opackets   | Number of packets sent on interface.           |
| u_longlong_t obytes     | Number of bytes sent on interface.             |
| u_longlong_t oerrors    | Number of output errors on interface.          |
| u_longlong_t collisions | Number of collisions on <b>csma</b> interface. |

The **perfstat\_paging\_space\_t** structure contains the following members:

| <b>Item</b>                  | <b>Description</b>     |
|------------------------------|------------------------|
| char name[IDENTIFIER_LENGTH] | Paging space name.     |
| char type                    | Type of paging device. |

The possible values of the members are as follows:

| <b>Item</b> | <b>Description</b> |
|-------------|--------------------|
| LV_PAGING   | Logical volume.    |
| NFS_PAGING  | NFS file.          |

The **nfs\_paging** union has the following fields:

| <b>Item</b>                                 | <b>Description</b>          |
|---------------------------------------------|-----------------------------|
| char nfs_paging.hostname[IDENTIFIER_LENGTH] | Host name of paging server. |
| char nfs_paging.filename[IDENTIFIER_LENGTH] | Swap file name on server.   |

The **lv\_paging** union has the following fields:

| <b>Item</b>                              | <b>Description</b>                           |
|------------------------------------------|----------------------------------------------|
| char lv.paging.vgname[IDENTIFIER_LENGTH] | Volume group name.                           |
| longlong_t lp_size                       | Size in number of logical partitions.        |
| longlong_t mb_size                       | Size in megabytes.                           |
| longlong_t mb_used                       | Portion used in megabytes.                   |
| longlong_t io_pending                    | Number of pending I/O.                       |
| char active                              | Indicates if active (1 if yes, 0 if not).    |
| char automatic                           | Indicates if automatic (1 if yes, 0 if not). |

The list of the paging spaces and the automatic, type, lpsize, mbsize, host name, file name, and vgname members of the **perfstat\_pagingspace\_t** structure are stored in the information cache. They can be flushed by making one of the following calls:

- `perfstat_reset()`
- `perfstat_partial_reset(NULL, FLUSH_PAGINGSPACE)`
- `perfstat_partial_reset("paging space name", FLUSH_PAGINGSPACE)`

The **perfstat\_netbuffer\_t** structure contains the following members:

| <b>Item</b>                  | <b>Description</b>                                                      |
|------------------------------|-------------------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH] | Size in ASCII. It is always a power of 2. For example, 32, 64, and 128. |
| u_longlong_t inuse           | Number of buffer currently allocated.                                   |
| u_longlong_t calls           | Number of buffer allocations since last reset.                          |
| u_longlong_t delayed         | Number of delayed allocations.                                          |
| u_longlong_t free            | Number of free calls.                                                   |
| u_longlong_t failed          | Number of failed allocations.                                           |
| u_longlong_t highwatermark   | High threshold for number of buffer allocated.                          |
| u_longlong_t freed           | Number of buffers freed.                                                |

The **perfstat\_protocol\_t** structure contains the following members:

| <b>Item</b>                  | <b>Description</b>                                       |
|------------------------------|----------------------------------------------------------|
| char name[IDENTIFIER_LENGTH] | ip, ipv6, icmp, icmpv6, udp, tcp, rpc, nfs, nfsv2, nfsv8 |

The **ip** union contains the following fields:

| <b>Item</b>                                  | <b>Description</b>               |
|----------------------------------------------|----------------------------------|
| <code>u_llonglong_t ip.ipackets</code>       | Number of input packets.         |
| <code>u_llonglong_t ip.ierrors</code>        | Number of input errors.          |
| <code>u_llonglong_t ip.iqueueoverflow</code> | Number of input queue overflows. |
| <code>u_llonglong_t ip.opackets</code>       | Number of output packets.        |
| <code>u_llonglong_t ip.oerrors</code>        | Number of output errors.         |

The **ipv6** union contains the following fields:

| <b>Item</b>                                    | <b>Description</b>               |
|------------------------------------------------|----------------------------------|
| <code>u_llonglong_t ipv6.ipackets</code>       | Number of input packets.         |
| <code>u_llonglong_t ipv6.ierrors</code>        | Number of input errors.          |
| <code>u_llonglong_t ipv6.iqueueoverflow</code> | Number of input queue overflows. |
| <code>u_llonglong_t ipv6.opackets</code>       | Number of output packets.        |
| <code>u_llonglong_t ipv6.oerrors</code>        | Number of output errors.         |

The **icmp** union contains the following fields:

| <b>Item</b>                              | <b>Description</b>          |
|------------------------------------------|-----------------------------|
| <code>u_llonglong_t icmp.received</code> | Number of packets received. |
| <code>u_llonglong_t icmp.sent</code>     | Number of packets sent.     |
| <code>u_llonglong_t icmp.errors</code>   | Number of errors.           |

The **icmpv6** union contains the following fields:

| <b>Item</b>                                | <b>Description</b>          |
|--------------------------------------------|-----------------------------|
| <code>u_llonglong_t icmpv6.received</code> | Number of packets received. |
| <code>u_llonglong_t icmpv6.sent</code>     | Number of packets sent.     |
| <code>u_llonglong_t icmpv6.errors</code>   | Number of errors.           |

The **udp** union contains the following fields:

| <b>Item</b>                              | <b>Description</b>                          |
|------------------------------------------|---------------------------------------------|
| <code>u_llonglong_t udp.ipackets</code>  | Number of input packets.                    |
| <code>u_llonglong_t udp.ierrors</code>   | Number of input errors.                     |
| <code>u_llonglong_t udp.opackets</code>  | Number of output packets.                   |
| <code>u_llonglong_t udp.no_socket</code> | Number of packets dropped due to no socket. |

The **tcp** union contains the following fields:

| <b>Item</b>                                | <b>Description</b>                 |
|--------------------------------------------|------------------------------------|
| <code>u_llonglong_t tcp.ipackets</code>    | Number of input packets.           |
| <code>u_llonglong_t tcp.ierrors</code>     | Number of input errors.            |
| <code>u_llonglong_t tcp.opackets</code>    | Number of output packets.          |
| <code>u_llonglong_t tcp.initiated</code>   | Number of connections initiated.   |
| <code>u_llonglong_t tcp.accepted</code>    | Number of connections accepted.    |
| <code>u_llonglong_t tcp.established</code> | Number of connections established. |
| <code>u_llonglong_t tcp.dropped</code>     | Number of connections dropped.     |

The **rpc** union contains the following fields:

| <b>Item</b>                               | <b>Description</b>                                     |
|-------------------------------------------|--------------------------------------------------------|
| u_longlong_t rpc.client.stream.calls      | Total NFS client RPC connection-oriented calls.        |
| u_longlong_t rpc.client.stream.badcalls   | Rejected NFS client RPC calls.                         |
| u_longlong_t rpc.client.stream.badxids    | Bad NFS client RPC call responses.                     |
| u_longlong_t rpc.client.stream.timeouts   | Timed out NFS client RPC calls with no reply.          |
| u_longlong_t rpc.client.stream.newcreds   | Total NFS client RPC authentication refreshes.         |
| u_longlong_t rpc.client.stream.badverfs   | Total NFS client RPC bad verifier in response.         |
| u_longlong_t rpc.client.stream.timers     | NFS client RPC timeout greater than timeout value.     |
| u_longlong_t rpc.client.stream.nomem      | NFS client RPC calls memory allocation failure.        |
| u_longlong_t rpc.client.stream.cantconn   | Failed NFS client RPC calls.                           |
| u_longlong_t rpc.client.stream.interrupts | NFS client RPC calls fail due to interrupt.            |
| u_longlong_t rpc.client.dgram.calls       | Total NFS client RPC connectionless calls.             |
| u_longlong_t rpc.client.dgram.badcalls    | Rejected NFS client RPC calls.                         |
| u_longlong_t rpc.client.dgram.retrans     | Retransmitted NFS client RPC calls.                    |
| u_longlong_t rpc.client.dgram.badxids     | Bad NFS client RPC call responses.                     |
| u_longlong_t rpc.client.dgram.timeouts    | Timed out NFS client RPC calls with no reply.          |
| u_longlong_t rpc.client.dgram.newcreds    | Total NFS client RPC authentication refreshes.         |
| u_longlong_t rpc.client.dgram.badverfs    | Total NFS client RPC bad verifier in response.         |
| u_longlong_t rpc.client.dgram.timers      | NFS client RPC timeout greater than timeout value.     |
| u_longlong_t rpc.client.dgram.nomem       | NFS client RPC calls memory allocation failure.        |
| u_longlong_t rpc.client.dgram.cantsend    | NFS client RPC calls not sent.                         |
| u_longlong_t rpc.server.stream.calls      | Total NFS server RPC connection-oriented requests.     |
| u_longlong_t rpc.server.stream.badcalls   | Rejected NFS server RPC requests.                      |
| u_longlong_t rpc.server.stream.nullrecv   | NFS server RPC calls failed due to unavailable packet. |
| u_longlong_t rpc.server.stream.badlen     | NFS server RPC requests failed due to bad length.      |
| u_longlong_t rpc.server.stream.xdrcall    | NFS server RPC requests failed due to bad header.      |
| u_longlong_t rpc.server.stream.dupchecks  | NFS server RPC calls found in request cache.           |
| u_longlong_t rpc.server.stream.dupreqs    | Total NFS server RPC call duplicates.                  |
| u_longlong_t rpc.server.dgram.calls       | Total NFS server RPC connectionless requests.          |
| u_longlong_t rpc.server.dgram.badcalls    | Rejected NFS server RPC requests.                      |
| u_longlong_t rpc.server.dgram.nullrecv    | NFS server RPC calls failed due to unavailable packet. |
| u_longlong_t rpc.server.dgram.badlen      | NFS server RPC requests failed due to bad length.      |
| u_longlong_t rpc.server.dgram.xdrcall     | NFS server RPC requests failed due to bad header.      |
| u_longlong_t rpc.server.dgram.dupchecks   | NFS server RPC calls found in request cache.           |
| u_longlong_t rpc.server.dgram.dupreqs     | Total NFS server RPC call duplicates.                  |

The **nfs** union contains the following fields:

| <b>Item</b>                       | <b>Description</b>                            |
|-----------------------------------|-----------------------------------------------|
| u_longlong_t nfs.client.calls     | Total NFS client requests.                    |
| u_longlong_t nfs.client.badcalls  | Total NFS client failed calls.                |
| u_longlong_t nfs.client.clgets    | Total number of client NFS <b>clgets</b> .    |
| u_longlong_t nfs.client.cltoomany | Total number of client NFS <b>cltoomany</b> . |
| u_longlong_t nfs.server.calls     | Total NFS server requests.                    |
| u_longlong_t nfs.server.badcalls  | Total NFS server failed calls.                |
| u_longlong_t nfs.server.public_v2 | Total number of NFS version 2 server calls.   |
| u_longlong_t nfs.server.public_v3 | Total number of NFS version 3 server calls.   |

The **nfsv2** union contains the following fields:

| Item                                 | Description                                     |
|--------------------------------------|-------------------------------------------------|
| u_longlong_t nfsv2.client.calls      | NFS V2 client requests.                         |
| u_longlong_t nfsv2.client.null       | NFS V2 client null requests.                    |
| u_longlong_t nfsv2.client.getattr    | NFS V2 client <b>getattr</b> requests.          |
| u_longlong_t nfsv2.client.setattr    | NFS V2 client <b>setattr</b> requests.          |
| u_longlong_t nfsv2.client.root       | NFS V2 client <b>root</b> requests.             |
| u_longlong_t nfsv2.client.lookup     | NFS V2 client file name <b>lookup</b> requests. |
| u_longlong_t nfsv2.client.readlink   | NFS V2 client <b>readlink</b> requests.         |
| u_longlong_t nfsv2.client.read       | NFS V2 client read requests.                    |
| u_longlong_t nfsv2.client.writecache | NFS V2 client write cache requests.             |
| u_longlong_t nfsv2.client.write      | NFS V2 client write requests.                   |
| u_longlong_t nfsv2.client.create     | NFS V2 client file creation requests.           |
| u_longlong_t nfsv2.client.remove     | NFS V2 client file removal requests.            |
| u_longlong_t nfsv2.client.rename     | NFS V2 client file rename requests.             |
| u_longlong_t nfsv2.client.link       | NFS V2 client link creation requests.           |
| u_longlong_t nfsv2.client.symlink    | NFS V2 client symbolic link creation requests.  |
| u_longlong_t nfsv2.client.mkdir      | NFS V2 client directory creation requests.      |
| u_longlong_t nfsv2.client.rmdir      | NFS V2 client directory removal requests.       |
| u_longlong_t nfsv2.client.readdir    | NFS V2 client read-directory requests.          |
| u_longlong_t nfsv2.client.statsfs    | NFS V2 client file stat requests.               |
| u_longlong_t nfsv2.server.calls      | NFS V2 server requests.                         |
| u_longlong_t nfsv2.server.null       | NFS V2 server null requests.                    |
| u_longlong_t nfsv2.server.getattr    | NFS V2 server <b>getattr</b> requests.          |
| u_longlong_t nfsv2.server.setattr    | NFS V2 server <b>setattr</b> requests.          |
| u_longlong_t nfsv2.server.root       | NFS V2 server root requests.                    |
| u_longlong_t nfsv2.server.lookup     | NFS V2 server file name lookup requests.        |
| u_longlong_t nfsv2.server.readlink   | NFS V2 server <b>readlink</b> requests.         |
| u_longlong_t nfsv2.server.read       | NFS V2 server read requests.                    |
| u_longlong_t nfsv2.server.writecache | NFS V2 server cache requests.                   |
| u_longlong_t nfsv2.server.write      | NFS V2 server write requests.                   |
| u_longlong_t nfsv2.server.create     | NFS V2 server file creation requests.           |
| u_longlong_t nfsv2.server.remove     | NFS V2 server file removal requests.            |
| u_longlong_t nfsv2.server.rename     | NFS V2 server file rename requests.             |
| u_longlong_t nfsv2.server.link       | NFS V2 server link creation requests.           |
| u_longlong_t nfsv2.server.symlink    | NFS V2 server symbolic link creation requests.  |
| u_longlong_t nfsv2.server.mkdir      | NFS V2 server directory creation requests.      |
| u_longlong_t nfsv2.server.rmdir      | NFS V2 server directory removal requests.       |
| u_longlong_t nfsv2.server.readdir    | NFS V2 server read-directory requests.          |
| u_longlong_t nfsv2.server.statsfs    | NFS V2 server file stat requests.               |

The **nfsv3** union contains the following fields:

| Item                               | Description                                     |
|------------------------------------|-------------------------------------------------|
| u_longlong_t nfsv3.client.calls    | NFS V3 client calls.                            |
| u_longlong_t nfsv3.client.null     | NFS V3 client null requests.                    |
| u_longlong_t nfsv3.client.getattr  | NFS V3 client <b>getattr</b> requests.          |
| u_longlong_t nfsv3.client.setattr  | NFS V3 client <b>setattr</b> requests.          |
| u_longlong_t nfsv3.client.lookup   | NFS V3 client file name <b>lookup</b> requests. |
| u_longlong_t nfsv3.client.access   | NFS V3 client access requests.                  |
| u_longlong_t nfsv3.client.readlink | NFS V3 client <b>readlink</b> requests.         |

| unsigned:1 is_down            | State of the node is DOWN.                            |
| unsigned:1 is_down_not_posted | State of the node is DOWN, BUT NOT POSTED TO CLUSTER. |
| unsigned:1 is_deleted         | State of the node is DELETED.                         |
| unsigned:1 is_joined          | State of the node is JOINED.                          |

The **perfstat\_ip\_addr\_t** structure contains the following members:

| <b>Item</b>            | <b>Description</b> |
|------------------------|--------------------|
| sa_family_t the_family | Address family     |
| union ip               | IP address.        |

The **perfstat\_ip\_addr\_t.ip** structure contains the following members:

| Item                  | Description           |
|-----------------------|-----------------------|
| struct in_addr ip.ip4 | IP address Version 4. |
| struct in_addr ip.ip6 | IP address Version 6. |

The **perfstat\_disk\_data\_t** structure contains the following members:

| Item                          | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| char name[IDENTIFIER_LENGTH]  | Specifies the name of the disk.                                 |
| dev64_t cluster_dev_t         | Specifies the dev_t structure of the disk in the cluster.       |
| char uuid[ATTRVALSIZE]        | Specifies the universally unique identifier (UUID) of the disk. |
| char uid[ATTRVALSIZE]         | Specifies the unique disk identifier (UDID) of the disk.        |
| perfstat_disk_status_t status | Specifies the status of the disk.                               |

The **perfstat\_disk\_status\_t** structure contains the following members:

| Item                | Description                    |
|---------------------|--------------------------------|
| unsigned:1 is_found | Cluster disk is found.         |
| Unsigned:1 is_ready | Cluster disk is ready for use. |

The **perfstat\_processor\_pool\_util\_t** structure contains the following members:

| Item              | Description                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| max_capacity      | Maximum processor capacity of pool that is in a partition.                                                                                                                                                                                      |
| entitled_capacity | Entitled processor capacity of pool that is in a partition.                                                                                                                                                                                     |
| phys_cpus_pool    | Available physical processors in the shared processor pool, to which this partition belongs.                                                                                                                                                    |
| idle_cores        | Available physical processors in the shared processor pool over the last interval.                                                                                                                                                              |
| max_cores         | For the last interval, the total maximum number of cores that might be used by the shared processor pool, to which this partition belongs.                                                                                                      |
| busy_cores        | For the last interval, the total busy (nonidle) cores which are accumulated across all partitions in the shared processor pool to which this partition belongs.                                                                                 |
| sbusy_cores       | For the last interval, normalized total busy (nonidle) cores which are accumulated across all partitions in the shared processor pool to which this partition belongs. This is true when the processor cores run at nominal or rated frequency. |
| gpool_tot_cores   | For the last interval, total cores, across all physical processors that are allocated for the shared processor pool use (across all pools).                                                                                                     |
| gpool_busy_cores  | For the last interval, the total of busy (non-idle) cores which are accumulated across all shared processor partitions (across all pools).                                                                                                      |
| gpool_sbusy_cores | For last interval, the normalized total busy cores which are accumulated across all shared processor partitions (across all pools). This is true when the processor cores run at nominal or rated frequency.                                    |
| ssp_id            | Identifier of shared pool of the physical processors to which this partition belongs.                                                                                                                                                           |
| tb_last_delta     | Elapsed number of clock ticks.                                                                                                                                                                                                                  |
| version           | Version number for the data structure.                                                                                                                                                                                                          |

The node/cluster statistics collection must be enabled by using the following call:

```
perfstat_config(PERFSTAT_ENABLE | PERFSTAT_CLUSTER_STATS, NULL)
```

The node/cluster statistics collection must be disabled after collecting the data by using the following call:

```
perfstat_config(PERFSTAT_DISABLE | PERFSTAT_CLUSTER_STATS, NULL)
```

The **perfstat\_netadapter\_t** structure contains the following members:

| Item                                       | Description                                                                                                                       |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| adapter_type                               | Physical Ethernet Adapter                                                                                                         |
|                                            | Shared Ethernet Adapter (SEA)                                                                                                     |
|                                            | Virtual Ethernet Adapter                                                                                                          |
|                                            | Host Ethernet Adapter                                                                                                             |
| u_longlong_t version                       | The version number (1, 2, and so on).                                                                                             |
| char name[IDENTIFIER_LENGTH]               | Name of the adapter.                                                                                                              |
| u_longlong_t tx_packets                    | Transmit packets on the interface.                                                                                                |
| u_longlong_t tx_bytes                      | Transmit bytes on the interface.                                                                                                  |
| u_longlong_t tx_interrupts                 | Transfer interrupts.                                                                                                              |
| u_longlong_t tx_errors                     | Transmit errors.                                                                                                                  |
| u_longlong_t tx_packets_dropped            | Packets that are dropped at the time of data transmission.                                                                        |
| u_longlong_t tx_queue_size                 | Maximum packets on the software transmit queue.                                                                                   |
| u_longlong_t tx_queue_len                  | Transmission queue length.                                                                                                        |
| u_longlong_t tx_queue_overflow             | Transmission queue overflow.                                                                                                      |
| u_longlong_t tx_broadcast_packets          | Number of broadcast packets transmitted.                                                                                          |
| u_longlong_t tx_multicast_packets          | Number of multicast packets transmitted.                                                                                          |
| u_longlong_t tx_carrier_sense              | Lost carrier sense signal count.                                                                                                  |
| u_longlong_t tx_lost_CTS_errors            | The number of unsuccessful transmissions due to the loss of the clear-to-send signal error.                                       |
| u_longlong_t tx_DMA_underrun               | Number of DMA underruns for transmission.                                                                                         |
| u_longlong_t tx_max_collision_errors       | Maximum collision errors at transmission.                                                                                         |
| u_longlong_t tx_late_collision_errors      | Late collision errors at transmission.                                                                                            |
| u_longlong_t tx_deferred                   | The number of packets that are deferred for transmission.                                                                         |
| u_longlong_t tx_timeout_errors             | Time out errors for transmission.                                                                                                 |
| u_longlong_t tx_single_collision_count     | Number of single collision errors at transmission.                                                                                |
| u_longlong_t tx_multiple_collision_Count   | Number of multiple collision errors at transmission.                                                                              |
| u_longlong_t rx_packets                    | Received packets on interface.                                                                                                    |
| u_longlong_t rx_bytes                      | Received bytes on interface.                                                                                                      |
| u_longlong_t rx_errors                     | Input errors on interface.                                                                                                        |
| u_longlong_t rx_packets_dropped            | The number of packets that are accepted by the device driver for transmission that were not (for any reason) given to the device. |
| u_longlong_t rx_bad_packets                | Number of bad packets received.                                                                                                   |
| u_longlong_t rx_multicast_packets          | Number of multicast packets received.                                                                                             |
| u_longlong_t rx_broadcast_packets          | Number of broadcast packets received.                                                                                             |
| u_longlong_t rx_CRC_errors;                | Number of packets received with the CRC errors.                                                                                   |
| u_longlong_t rx_DMA_overrun;               | Number of the DMA overruns for the received data.                                                                                 |
| u_longlong_t rx_alignment_errors           | Packets received with an alignment error.                                                                                         |
| u_longlong_t rx_noresource_errors          | Packets received with no resource errors.                                                                                         |
| u_longlong_t rx_collision_errors           | Packets received with collision errors.                                                                                           |
| u_longlong_t rx_packet_tooshort_errors     | Number of short packets received.                                                                                                 |
| u_longlong_t rx_packet_toolong_errors      | Number of packets received that are too long.                                                                                     |
| u_longlong_t rx_packets_discardedbyadapter | Number of received packets that are discarded by the adapter.                                                                     |

The **perfstat\_fcstat\_t** structure contains the following members:

| Item                         | Description                                      |
|------------------------------|--------------------------------------------------|
| adapter_type                 | Fibre Channel                                    |
|                              | Virtual Fiber Channel Adapter                    |
| u_longlong_t version         | The version number (1, 2, and so on).            |
| char name[IDENTIFIER_LENGTH] | Name of the adapter.                             |
| u_longlong_t InputRequests   | Number of input requests.                        |
| u_longlong_t OutputRequests  | Number of output requests.                       |
| u_longlong_t InputBytes      | Number of input bytes.                           |
| u_longlong_t OutputBytes     | Number of output bytes.                          |
| u_longlong_t EffMaxTransfer  | Effective maximum transfer value of the adapter. |

| Item                                      | Description                                                                                                                                             |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t NoDMAResourceCnt             | Number of the DMA failures caused due to no DMA resource available.                                                                                     |
| u_longlong_t NoCmdResourceCnt             | Number of failures to allocate a command due to unavailability of command resource.                                                                     |
| int AttentionType                         | Link up or down the indicator.                                                                                                                          |
| u_longlong_t SecondsSinceLastReset        | Displays the seconds since the last reset of the statistics on the adapter.                                                                             |
| u_longlong_t TxFrames                     | Number of frames transmitted.                                                                                                                           |
| u_longlong_t TxWords                      | Fiber Channel Kbytes transmitted.                                                                                                                       |
| u_longlong_t RxFrames                     | Number of frames received.                                                                                                                              |
| u_longlong_t RxWords                      | Fiber Channel Kbytes received.                                                                                                                          |
| u_longlong_t LIPCount                     | Number of loop initialization protocol (LIP) events received in case we have FC-AL (arbitrated loop which is a FC topology).                            |
| u_longlong_t NOSCount                     | Number of Not_Operational (NOS) events. This indicates a link failure state. At a high level, this indicates that the connection to FC network is lost. |
| u_longlong_t ErrorFrames                  | Number of frames received with the CRC error.                                                                                                           |
| u_longlong_t DumpedFrames                 | Number of lost frames.                                                                                                                                  |
| u_longlong_t LinkFailureCount             | Number of link failures.                                                                                                                                |
| u_longlong_t LossofSyncCount              | Number of loss of sync.                                                                                                                                 |
| _longlong_t LossofSignal                  | Number of signal lost.                                                                                                                                  |
| u_longlong_t PrimitiveSeqProtocolErrCount | Number of times a primitive sequence was in error.                                                                                                      |
| u_longlong_t InvalidTxWordCount           | Number of invalid transmission words received.                                                                                                          |
| u_longlong_t InvalidCRCCount              | Number of CRC errors in a received frame.                                                                                                               |
| u_longlong_t PortFcId                     | SCSI ID of the adapter.                                                                                                                                 |
| u_longlong_t PortSpeed                    | Speed of the adapter in Gb (gigabits).                                                                                                                  |
| char PortType[PERFSTAT_SIZE]              | Type of connection. Valid values are fabric, private loop, point-to-point, and unknown.                                                                 |
| u_longlong_t PortWWN                      | Worldwide port name.                                                                                                                                    |
| u_longlong_t PortSupportedSpeed           | Supported port speed in GB (gigabits).                                                                                                                  |
| vfc_name[IDENTIFIER_LENGTH]               | Name of the Virtual Fiber Channel (VFC) adapter.                                                                                                        |

The **perfstat\_thread\_t** structure contains the following members:

| Item                 | Description                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t version | Version number of the data structure.                                                                                                                                          |
| u_longlong_t pid     | Process ID of the kernel thread.                                                                                                                                               |
| u_longlong_t tid     | Kernel thread ID.                                                                                                                                                              |
| u_longlong_t cpuid   | Processor ID to which the thread is bound to.                                                                                                                                  |
| double ucpu_time     | User mode CPU time is in percentage or milliseconds, which is based on whether it is filled by <b>perfstat_thread_util</b> or <b>perfstat_thread</b> structure respectively.   |
| double scpu_time     | System mode CPU time is in percentage or milliseconds, which is based on whether it is filled by <b>perfstat_thread_util</b> or <b>perfstat_thread</b> structure respectively. |

The following are declared as functions:

```

int perfstat_cpu(perfstat_id_t *name,
 perfstat_cpu_t *userbuff,
 int sizeof_userbuff,
 int desired_number)
int perfstat_cpu_node(perfstat_id_node_t *name,

The **perfstat\_cpu\_util\_t** structure contains the following members:

| <b>Item</b>                    | <b>Description</b>                                                             |
|--------------------------------|--------------------------------------------------------------------------------|
| u_longlong_t version           | The version number (1, 2, and so on).                                          |
| char cpu_id[IDENTIFIER_LENGTH] | Holds the ID of the processors.                                                |
| float entitlement              | Percentage entitlement of the partition.                                       |
| float user_pct                 | Percentage of utilization in user mode.                                        |
| float kern_pct                 | Percentage of utilization in kernel mode.                                      |
| float idle_pct                 | Percentage of utilization in idle mode.                                        |
| float wait_pct                 | Percentage of utilization in wait mode.                                        |
| float physical_busy            | Physical processors busy.                                                      |
| float physical_consumed        | Total processors used up by the partition                                      |
| float freq_pct                 | Average frequency percentage over the last interval                            |
| float entitlement_pct          | Percentage of entitlement used.                                                |
| float busy_pct                 | Percentage of entitlement busy.                                                |
| float idle_donated_pct         | Percentage idle cycles donated.                                                |
| float busy_donated_pct         | Percentage of busy cycles donated.                                             |
| float idle_stolen_pct          | Percentage idle cycles stolen.                                                 |
| float busy_stolen_pct          | Percentage busy cycles stolen.                                                 |
| float l_user_pct               | Percentage of utilization in user mode, in terms of logical processor ticks.   |
| float l_kern_pct               | Percentage of utilization in kernel mode, in terms of logical processor ticks. |
| float l_idle_pct               | Percentage of utilization in idle mode, in terms of logical processor ticks.   |
| float l_wait_pct               | Percentage of utilization in wait mode, in terms of logical processor ticks.   |
| u_longlong_t delta_time        | Delta time in milliseconds for which the utilization is evaluated.             |

The **perfstat\_ssp\_t** structure contains the following members:

| <b>Item</b>                      | <b>Description</b>                                                                                                                                                                                                                                                                                                                        |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| u_longlong_t version             | Version number for the data structure.                                                                                                                                                                                                                                                                                                    |
| char cluster_name[CLUSTERNAMELN] | Name of the cluster.                                                                                                                                                                                                                                                                                                                      |
| char spool_name[POOLNAME]        | Name of the shared storage pool.                                                                                                                                                                                                                                                                                                          |
| union u                          | Details of the shared storage pool.                                                                                                                                                                                                                                                                                                       |
| Char poolid[MAXPOOLIDSZ]         | The union structure has the following members:                                                                                                                                                                                                                                                                                            |
| char clusterid[VIOS_STR_128]     | <ul style="list-style-type: none"> <li>• struct global</li> <li>• perfstat_ssp_disk_data_t disk</li> <li>• struct vtd</li> <li>• perfstat_ssp_tier_t tier</li> <li>• perfstat_ssp_fg_t fg</li> <li>• perfstat_ssp_node_t node</li> </ul> Specifies the identifier of the shared storage pool.<br>Specifies the identifier of the Cluster. |

The **struct global** structure contains the following members:

| <b>Item</b>                                | <b>Description</b>                                    |
|--------------------------------------------|-------------------------------------------------------|
| <code>u_longlong_t total_space</code>      | Specifies the total space in the shared storage pool. |
| <code>u_longlong_t total_used_space</code> | Specifies the used space in the shared storage pool.  |

The `perfstat_ssp_disk_data_t` structure contains the following members:

| <b>Item</b>                              | <b>Description</b>                                       |
|------------------------------------------|----------------------------------------------------------|
| <code>char diskname[]</code>             | Specifies the disk name.                                 |
| <code>char uid[ATTRVALSIZE]</code>       | Specifies the unique disk identifier (UDID) of the disk. |
| <code>unsigned long long capacity</code> | Specifies the capacity of the disk.                      |
| <code>char tiername[128]</code>          | Specifies the tier name that contains the disk.          |
| <code>char fgname[128]</code>            | Specifies the failure group name that contains the disk. |
| <code>unsigned long long fgid</code>     | Specifies the failure group ID that contains the disk.   |
| <code>unsigned long long tierid</code>   | Specifies the tier ID that contains the disk.            |
| <code>unsigned long long free</code>     | Specifies the available size in the physical volume.     |

The `struct vtd` structure contains the following members:

| <b>Item</b>                                   | <b>Description</b>                                                             |
|-----------------------------------------------|--------------------------------------------------------------------------------|
| <code>char vtd_name[IDENTIFIER_LENGTH]</code> | Specifies the virtual target device (VTD) name.                                |
| <code>char lu_name[IDENTIFIER_LENGTH]</code>  | Specifies the logical unit name.                                               |
| <code>char lu_type[IDENTIFIER_LENGTH]</code>  | Specifies the logical unit type.                                               |
| <code>u_longlong_t lu_size</code>             | Specifies the size of the logical unit.                                        |
| <code>u_longlong_t lu_free</code>             | Specifies the free space that is available in logical unit.                    |
| <code>u_longlong_t lu_usage</code>            | Specifies the physical usage of logical unit in MB.                            |
| <code>int client_id</code>                    | Specifies the virtual I/O client ID.                                           |
| <code>char mtm[128]</code>                    | Specifies the Machine Type Model (MTM).                                        |
| <code>char drcname[VIOS_STR_256]</code>       | Specifies the DLPAR resource connector (DRC) name of the Virtual Host Adapter. |
| <code>char lu_udid[VIOS_UDID_LENGTH]</code>   | Specifies the unique device identifier (UDID) for the Virtual Host Adapter.    |

The `perfstat_ssp_tier_t` structure contains the following members:

| <b>Item</b>                            | <b>Description</b>             |
|----------------------------------------|--------------------------------|
| <code>char tiername[128]</code>        | Specifies the tier name.       |
| <code>unsigned long long tierid</code> | Specifies the tier identifier. |

The `perfstat_ssp_fg_t` structure contains the following members:

| <b>Item</b>                            | <b>Description</b>                                       |
|----------------------------------------|----------------------------------------------------------|
| <code>char fgname[128]</code>          | Specifies the name of the failure group.                 |
| <code>unsigned long long fgid</code>   | Specifies the identifier of the failure group.           |
| <code>char tiername[128]</code>        | Specifies the tier name that contains the failure group. |
| <code>unsigned long long tierid</code> | Specifies the tier ID that contains the failure group.   |

The `perfstat_ssp_id_t` structure contains the following members:

| <b>Item</b>          | <b>Description</b>                             |
|----------------------|------------------------------------------------|
| unsigned int version | Version number for the data structure          |
| int spec             | Specifies the filter.                          |
| sspfILTER_t pool     | Specifies the pool details to filter.          |
| sspfILTER_t tier     | Specifies the tier details to filter.          |
| sspfILTER_t fg       | Specifies the failure group details to filter. |
| sspfILTER_t pv       | Specifies the disk details to filter.          |
| perfstat_id_t node   | Specifies the node name to filter.             |

The `sspfILTER_t` structure contains the following members:

| <b>Item</b>           | <b>Description</b>                      |
|-----------------------|-----------------------------------------|
| char name[128]        | Specifies the name of the filter.       |
| unsigned long long id | Specifies the identifier of the filter. |

The `perfstat_ssp_node_t` structure contains the following members:

| <b>Item</b>                   | <b>Description</b>                                         |
|-------------------------------|------------------------------------------------------------|
| char hostname[MAXHOSTNAMELEN] | Specifies the node name.                                   |
| char mtms[256]                | Specifies the machine type and serial number of the node.  |
| char ip[MAXHOSTNAMELEN]       | Specifies the IP address of the host.                      |
| unsigned int lparid           | Specifies the LPAR identifier of the node.                 |
| char ioslevel[256]            | Specifies the operating system level of the node.          |
| unsigned int status           | Specifies the state of the node: VIO_DOWN or VIO_UP.       |
| unsigned int poolstatus       | Specifies the pool status of the node: VIO_DOWN or VIO_UP. |

## math.h File

### Purpose

Defines math subroutines and constants.

### Description

The `/usr/include/math.h` header file contains declarations of all the subroutines in the Math library (**libm.a**) and of various subroutines in the Standard C Library (**libc.a**) that return floating-point values.

Among other things, the **math.h** file defines the following macro, which is used as an error-return value:

| <b>Item</b>     | <b>Description</b>                                                                                                                                 |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HUGE_VAL</b> | Specifies the maximum value of a double-precision floating-point number: +infinity on machines that support IEEE-754 and <b>DBL_MAX</b> otherwise. |

If you define the `_MATH_` preprocessor variable before including the **math.h** file, the **math.h** file defines macros that make the names of certain math subroutines appear to the compiler as `_xxxx`. The following names are redefined to have the `_` (double underscore) prefix:

| Item               | Description        |
|--------------------|--------------------|
| <code>exp</code>   | <code>sin</code>   |
| <code>asin</code>  | <code>log</code>   |
| <code>cos</code>   | <code>acos</code>  |
| <code>log10</code> | <code>tan</code>   |
| <code>atan</code>  | <code>sqr</code>   |
| <code>fabs</code>  | <code>atan2</code> |

These special names instruct the C compiler to generate code that avoids the overhead of the Math library subroutines and issues compatible-mode floating-point subroutines directly. The `_MATH_` variable is defined by default.

If `_XOPEN_SOURCE` variable is defined, the following mathematical constants are defined for your convenience. The values are of type double and are accurate to the precision of this type. That is, the machine value is the mathematical value rounded to double precision.

| Item                    | Description                                                    |
|-------------------------|----------------------------------------------------------------|
| <code>M_E</code>        | Base of natural logarithms ( $e$ )                             |
| <code>M_LOG2E</code>    | Base-2 logarithm of $e$                                        |
| <code>M_LOG10E</code>   | Base-10 logarithm of $e$                                       |
| <code>M_LN2</code>      | Natural logarithm of 2                                         |
| <code>M_LN10</code>     | Natural logarithm of 10                                        |
| <code>M_PI</code>       | Pi, the ratio of the circumference of a circle to its diameter |
| <code>M_PI_2</code>     | Value of pi divided by 2                                       |
| <code>M_PI_4</code>     | Value of pi divided by 4                                       |
| <code>M_1_PI</code>     | Value of 1 divided by pi                                       |
| <code>M_2_PI</code>     | Value of 2 divided by pi                                       |
| <code>M_2_SQRTPI</code> | Value of 2 divided by the positive square root of pi           |
| <code>M_SQRT2</code>    | Positive square root of 2                                      |
| <code>M_SQRT1_2</code>  | Positive square root of 1/2                                    |

## mode.h File

### Purpose

Defines the interpretation of a file mode.

### Description

This version of the operating system supports a 32-bit mode, which is divided into 3 parts. The 16 most significant bits are reserved by the system. The least significant 16 bits define the type of file (`S_IFMT`) and the permission bits. The 12 permission bits can be changed by using the `chmod` or `chacl` subroutine. The file type cannot be changed.

### File-Type Bits

The file type determines the operations that can be applied to the file (including implicit operations, such as searching a directory or following a symbolic link). The file type is established when the file is created, and cannot be changed. The following file types are supported:

| Item     | Description                 |
|----------|-----------------------------|
| S_IFDIR  | Defines a directory.        |
| S_IFREG  | Defines a regular file.     |
| S_IFIFO  | Defines a pipe.             |
| S_IFCHR  | Defines a character device. |
| S_IFBLK  | Defines a block device.     |
| S_IFLNK  | Defines a symbolic link.    |
| S_IFSOCK | Defines a socket.           |

The **S\_IFMT** format mask constant can be used to mask off a file type from the mode.

### File-Attribute Bits

The file-attribute bits affect the interpretation of a particular file. With some restrictions, file attributes can be changed by the owner of a file or by a privileged user. The file-attribute bits are:

| Item      | Description |
|-----------|-------------|
| Attribute | Description |

### S\_ISUID Bit

| Item   | Description                                                                                                                                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| setuid | When a process runs a regular file that has the <b>S_ISUID</b> bit set, the effective user ID of the process is set to the owner ID of the file. The <b>setuid</b> attribute can be set only by a process on a trusted path. If the file or its access permissions are altered, the <b>S_ISUID</b> bit is cleared. |

### S\_ISGID (S\_ENFMT) Bit

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| setgid           | When a process runs a regular file that has both the <b>S_ISGID</b> bit and the <b>S_IXGRP</b> permission bit set, the effective user ID of the process is set to the group ID of the file. The <b>setgid</b> attribute can be set only by a process on a trusted path. If the owner is establishing this attribute, the group of the file must be the effective group ID or in the supplementary group ID of the process. If the file or its access permissions are altered, the <b>S_ISGID</b> bit is cleared. |
| enforced locking | If a regular file has the <b>S_ISGID</b> bit set and the <b>S_IXGRP</b> permission bit cleared, locks placed on the file with the <b>lockfx</b> subroutine are enforced locks.                                                                                                                                                                                                                                                                                                                                   |

### S\_IFMPX Bit

| Item        | Description                                                                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| multiplexed | A character device with the <b>S_IFMPX</b> attribute bit set is a multiplexed device. This attribute is established when the device is created. |

### S\_ISVTX Bit

| Item   | Description                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------|
| sticky | If a directory has the <b>S_SVTX</b> bit set, only the owner of the file or the owner of the directory can remove a file from the directory. |

### S\_IXACL Bit

| Item                | Description                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| access control list | Any file that has the <b>S_IXACL</b> bit set can have an extended access control list (ACL). Specifying this bit when setting the mode with the <b>chmod</b> command causes the permission bits information in the mode to be ignored. Extended ACL entries are ignored if this bit is cleared. This bit can be implicitly cleared by the <b>chmod</b> subroutine. The <i>/usr/include/sys/acl.h</i> file defines the format of the ACL. |

### S\_ITCB Bit

| Item    | Description                                                                                                                                                                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| trusted | Any file that has the <b>S_ITCB</b> bit set is part of the Trusted Computing Base (TCB). Only files in the TCB can acquire privilege on a trusted path. Only files in the TCB are run by the trusted shell (which is invoked with the <b>tsh</b> command). This attribute can be established or cleared only by a process running on the trusted path. |

### S\_IJRNL Bit

| Item        | Description                                                                                                                                                                                                                     |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| journalized | Any file that has the <b>S_IJRNL</b> bit set is defined as a journaled file. Updates to a journaled file are added to a log atomically. All directories and system files have the journalized attribute, which cannot be reset. |

### S\_ICRYPTO Bit

| Item      | Description                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------|
| encrypted | Any file that has the <b>S_ICRYPTO</b> bit set is an encrypted file in an Encrypting File System (EFS). |

### File-Permission Bits

The file-permission bits control which processes can perform operations on a file. This includes read, write, and execute bits for the file owner, the file group, and the default. These bits should not be used to set access-control information; the ACL should be used instead. The file-permission bits are:

| Item            | Description                                                                        |
|-----------------|------------------------------------------------------------------------------------|
| <b>S_IRWXU</b>  | Permits the owner of a file to read, write, and execute the file.                  |
| <b>S_IRUSR</b>  | Permits the owner of a file to read the file.                                      |
| <b>S_IREAD</b>  | Permits the owner of a file to read the file.                                      |
| <b>S_IWUSR</b>  | Permits the owner of a file to write to the file.                                  |
| <b>S_IWRITE</b> | Permits the owner of a file to write to the file.                                  |
| <b>S_IXUSR</b>  | Permits the owner of a file to execute the file or to search the file's directory. |
| <b>S_IEXEC</b>  | Permits the owner of a file to execute the file or to search the file's directory. |
| <b>S_IRWXG</b>  | Permits a file's group to read, write, and execute the file.                       |
| <b>S_IRGRP</b>  | Permits a file's group to read the file.                                           |
| <b>S_IWGRP</b>  | Permits a file's group to write to the file.                                       |
| <b>S_IXGRP</b>  | Permits a file's group to execute the file or to search the file's directory.      |
| <b>S_IRWXO</b>  | Permits others to read, write, and execute the file.                               |
| <b>S_IROTH</b>  | Permits others to read the file.                                                   |
| <b>S_IWOTH</b>  | Permits others to write to the file.                                               |
| <b>S_IXOTH</b>  | Permits others to execute the file or to search the file's directory.              |

## msg.h File

### Purpose

Describes the structures that are used by the subroutines that perform message queueing operations.

### Syntax

```
#include <sys/msg.h>
```

### Description

The **msg.h** file defines the following symbolic constants, types, and structures:

**Types:**

```
unsigned int msgqnum_t;
unsigned int msglen_t;
```

**Symbolic Constants:**

| Item         | Description                                       |
|--------------|---------------------------------------------------|
| MSG_NOERROR  | no error if big message */                        |
| MSG_R        | read permission */                                |
| MSG_W        | write permission */                               |
| MSG_RWAIT    | a reader is waiting for a message */              |
| MSG_WWAIT    | a writer is waiting to send */                    |
| MSG_STAT     | Number of bytes to copy for IPC_STAT command      |
| MSGXBUFSIZE  | the length of everything but mtext[1] and padding |
| MSG_SYSSPACE | for msgsnd() flags                                |
| XMSG         | for msgrcv() flags                                |

There is one msg queue id data structure for each q in the system. The **msqid\_ds** structure contains the following members:

```
struct ipc_perm msg_perm; operation permission
struct
void *msg_first; ptr to first message on q
void *msg_last; ptr to last message on q
unsigned int __msg_cbytes; current # bytes on q
msgqnum_t msg_qnum; # of messages on q
msglen_t msg_qbytes; max # of bytes on q
pid_t msg_lspid; pid of last msgsnd
pid_t msg_lrpid; pid of last msgrcv
time_t msg_stime; last msgsnd time
time_t msg_rttime; last msgrcv time
time_t msg_ctime; last change time
int __msg_rwait; wait list for message
receive
int __msg_wwait; wait list for message send
unsigned short __msg_revents; select/poll requested
events
```

The **msg\_hdr** struct contains the following members:

|        |        |                        |
|--------|--------|------------------------|
| time_t | mtime; | time message was sent  |
| uid_t  | uid;   | author's effective uid |
| gid_t  | gid;   | author's effective gid |
| pid_t  | pid;   | author's process id    |
| mtyp_t | mtype; | message type           |

There is one msg structure for each message that may be in the system. The msg structure contains the following members:

|                |            |                          |
|----------------|------------|--------------------------|
| struct msg     | *msg_next; | ptr to next message on q |
| struct msg_hdr | msg_attr;  | message attributes       |
| unsigned int   | msg_ts;    | message text size        |
| char           | *msg_spot; | pointer to message text  |

The structure **msgbuf** is the user message buffer template for **msgsnd** and **msgrcv** system calls and contains the following members:

|        |           |              |
|--------|-----------|--------------|
| mtyp_t | mtype;    | message type |
| char   | mtext[1]; | message text |

The **msgxbuf** structure is the user message buffer template for the **msgxrcv** system call and contains the following members:

|        |           |                        |
|--------|-----------|------------------------|
| time_t | mtime;    | time message was sent  |
| uid_t  | uid;      | author's effective uid |
| gid_t  | gid;      | author's effective gid |
| pid_t  | pid;      | author's process id    |
| mtyp_t | mtype;    | Message type           |
| char   | mtext[1]; | Message text           |

The **msginfo** structure contains the following members:

|     |         |                                     |
|-----|---------|-------------------------------------|
| int | msgmax, | max message size                    |
| int | msgmnb, | max # bytes on queue                |
| int | msgmni, | # of message queue identifiers      |
| int | msgmm;  | max # messages per queue identifier |

The **time\_t**, **size\_t**, **off\_t**, **mtyp\_t**, **pid\_t**, and **gid\_t** types are as defined in **<sys/types.h>**.

The following are declared as functions:

```
int msgget(key_t, int);
int msgrcv(int, void *, size_t, long, int);
int msgsnd(int, const void *, size_t, int);
int msgctl(int, int, struct msqid_ds *);
int msgxrcv(int, struct msgxbuf*, int, long, int);
```

In addition, all of the symbols from **<sys/ipc.h>** will be defined when this header is included.

## mtio.h File

### Purpose

Defines the user include file for the magnetic tape.

## Description

The `/usr/include/sys/mtio.h` file is for use with devices that are driven by the magnetic tape driver. Since Linux operating system has an `mtio.h` file, the `sys/mtio.h` file has been added for Linux compatibility. The `sys/mtio.h` file can be used for Linux source code compatibility.

**Note:** For Linux source-code compatibility (that is, source code or definitions based on the Linux operating system), set the following macro before including the `sys/mtio.h` file:

```
#define _LINUX_SOURCE_COMPAT
```

## File

`/usr/include/sys/mtio.h`

### param.h File

#### Purpose

Describes system parameters.

#### Description

Certain parameters vary for different hardware that uses the operating system. These parameters are defined in the `/usr/include/sys/param.h` file. The most significant parameters are:

| Item   | Description                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| NCARGS | Indicates the default number of characters, including terminating null characters, that can be passed using the <code>exec</code> subroutine. |
| UBSIZE | The unit used by the statistics subroutines for returning block sizes of files.                                                               |

This file also contains macros for manipulating machine-dependent fields.

Programs that are intended to comply with the POSIX standard should include the `/usr/include/sys/limits.h` file rather than the `param.h` file.

### pmapi.h File

#### Purpose

Describes the structures and constants used by the Performance Monitor APIs subroutines.

#### Syntax

```
#include <pmapi.h>
```

## Description

The **pmapi.h** file defines the following symbolic constants, types, and structures:

### Symbolic Constants

| Item             | Description                          |
|------------------|--------------------------------------|
| MAX_COUNTERS     | Maximum number of supported counters |
| MIN_THRESH_VALUE | Minimum threshold value              |
| MAX_THRESH_VALUE | Maximum threshold value              |
| COUNT_NOTHING    | Specifies to not count event         |

### Constants for event filters

| Item          | Description                                                                        |
|---------------|------------------------------------------------------------------------------------|
| PM_VERIFIED   | Specifies events that have been verified                                           |
| PM_UNVERIFIED | Specifies events that have not been verified                                       |
| PM_CAVEAT     | Specifies events that work with caveats                                            |
| PM_GET_GROUPS | Not a filter; specifies that supported event groups are to be returned by pm_init. |

### Constants for Processor Idents

| Item              | Description                                                                             |
|-------------------|-----------------------------------------------------------------------------------------|
| PM_CURRENT        | Specifies that the PMAPI is to be initialized for the current processor type.           |
| PM_PowerPC®604    | Specifies that supported events for the PowerPC®604 are to be returned.                 |
| PM_PowerPC®604e   | Specifies that supported events for the PowerPC604e are to be returned.                 |
| PM_RS64_II        | Specifies that supported events for the RS64-II are to be returned.                     |
| PM_POWER3         | Specifies that supported events for the POWER3 are to be returned.                      |
| PM_RS64_III       | Specifies that supported events for the RS64-III are to be returned.                    |
| PM_POWER3_II      | Specifies that supported events for the POWER3-II are to be returned.                   |
| PM_POWER4         | Specifies that supported events and/or groups for the POWER4 are to be returned.        |
| PM_MPC7450        | Specifies that supported events for the MPC7450 are to be returned                      |
| PM_POWER4_II      | Specifies that supported events and/or groups for the POWER4-II are to be returned.     |
| PM_POWER5         | Specifies that supported events and/or groups for the POWER5 are to be returned.        |
| PM_PowerPC 970    | Specifies that supported events and/or groups for the PowerPC 970 are to be returned.   |
| PM_POWER6®        | Specifies that supported events and/or groups for the POWER6® are to be returned.       |
| PM_PPowerPC 970MP | Specifies that supported events and/or groups for the PowerPC 970MP are to be returned. |
| PM_POWER7®        | Specifies that supported events and/or groups for the POWER7® are to be returned.       |
| PM_MAXPROCTYPE    | Maximum number of processor idents.                                                     |

### Constants for setting mode bits

| Item        | Description                    |
|-------------|--------------------------------|
| PM_PROCTREE | Turns process tree counting on |
| PM_COUNT    | Turns counting on immediately  |
| PM_USER     | Turns user mode counting on    |
| PM_KERNEL   | Turns kernel mode counting on  |
| PM_PROCESS  | Creates a process level group  |

The structure **pm\_info\_t** contains the following members:

|             |                |                                      |
|-------------|----------------|--------------------------------------|
| int         | maxpmcs        | number of available counters         |
| int         | *maxevents     | number of events for each hw counter |
| pm_events_t | **list_events  | list of available events             |
| int         | thresholdmult  | threshold multiplier                 |
| char        | *proc_name     | processor name                       |
| int         | hthresholdmult | upper threshold multiplier           |

The structure **pm\_events\_t** contains the following members:

|      |              |                                                                        |
|------|--------------|------------------------------------------------------------------------|
| int  | event_id     | event number                                                           |
| char | status       | 'v': verified<br>'u': unverified<br>'c': caveat                        |
| char | threshold    | 'y': thresholdable<br>'g': group-only<br>'G': thresholdable group-only |
| char | *short_name  | mnemonic name                                                          |
| char | *long_name   | long name                                                              |
| char | *description | full description                                                       |

The structure **pm\_info2\_t** contains the following members:

|              |                |                                      |
|--------------|----------------|--------------------------------------|
| int          | maxpmcs        | number of available counters         |
| int          | *maxevents     | number of events for each hw counter |
| pm_events2_t | **list_events  | list of available events             |
| int          | thresholdmult  | threshold multiplier                 |
| int          | hthresholdmult | upper threshold multiplier           |
| int          | Hthresholdmult | hyper threshold multiplier           |
| char         | *proc_name     | processor name                       |
| pm_feature_t | proc_feature   | processor feature list               |

The structure **pm\_events2\_t** contains the following members:

|             |              |                  |
|-------------|--------------|------------------|
| int         | event_id     | event number     |
| pm_status_t | status       | event status     |
| char        | *short_name  | mnemonic name    |
| char        | *long_name   | long name        |
| char        | *description | full description |

The structure **pm\_status\_t** contains the following members:

|            |                |                                                                      |
|------------|----------------|----------------------------------------------------------------------|
| unsigned:1 | b.unverified   | unverified event                                                     |
| unsigned:1 | b.verified     | verified event                                                       |
| unsigned:1 | b.caveat       | event verified with some caveat(see description)                     |
| unsigned:1 | b.group_only   | event can only be used within a group                                |
| unsigned:1 | b.threshold    | event can be used with a threshold                                   |
| unsigned:1 | b.shared       | event is shared between hardware threads                             |
| unsigned:1 | b.support_mode | support user, kernel, hypervisor and proctree counting modes applied |
| unsigned:1 | b.overflow     | generate an interrupt on overflow                                    |
| unsigned:1 | b.marked       | marked event                                                         |

The structure **pm\_feature\_t** contains the following members:

|            |              |                                       |
|------------|--------------|---------------------------------------|
| unsigned:1 | b.hypervisor | hypervisor counting mode is supported |
|------------|--------------|---------------------------------------|

The structure **pm\_groups\_info\_t** contains the following members:

|             |               |                            |
|-------------|---------------|----------------------------|
| int         | maxgroups     | number of available groups |
| pm_groups_t | *event_groups | list of event groups       |

The structure **pm\_groups\_t** contains the following members:

|      |              |                               |
|------|--------------|-------------------------------|
| int  | group_id     | group number                  |
| int  | *events      | events in this group, by ID # |
| char | *short_name  | mnemonic name                 |
| char | *long_name   | long name                     |
| char | *description | full description              |

The structure **pm\_prog\_t** contains the following members:

|            |                    |                                       |
|------------|--------------------|---------------------------------------|
| unsigned:6 | mode.b.threshold   | threshold value                       |
| unsigned:1 | mode.b.thresh_res  | uses upper threshold mutiplier if set |
| unsigned:1 | mode.b.thresh_hres | uses hyper threshold mutiplier if set |
| unsigned:1 | mode.b.nointerrupt | interrupt counting disable            |
| unsigned:1 | mode.b.runlatch    | runlatch enable/disable               |
| unsigned:1 | mode.b.is_group    | is an event group                     |

|            |                      |                                   |
|------------|----------------------|-----------------------------------|
| unsigned:1 | mode.b.process       | process level group indicator     |
| unsigned:1 | mode.b.hypervisor    | turns hypervisor mode counting on |
| unsigned:1 | mode.b.kernel        | turns kernel mode counting on     |
| unsigned:1 | mode.b.user          | turns user mode counting on       |
| unsigned:1 | mode.b.count         | counting state                    |
| unsigned:1 | mode.b.proctree      | turns process tree counting on    |
| int        | events[MAX_COUNTERS] | list of counted events            |

The structure **pm\_data\_t** contains the following members:

|            |                    |                   |
|------------|--------------------|-------------------|
| pm_ginfo_t | ginfo              | group information |
| long long  | accu[MAX_COUNTERS] | accumulated data  |

The structure **pm\_ginfo\_t** contains the following members:

|            |                    |                                    |
|------------|--------------------|------------------------------------|
| int        | members;           | number of threads in group         |
| unsigned:1 | flags.b.process    | process level group indicator      |
| unsigned:1 | flags.b.consistent | group data consistent with members |

The structure **pm\_accu\_time\_t** contains the following members:

|                  |               |                        |
|------------------|---------------|------------------------|
| timebasestruct_t | accu_timebase | accumulated time base  |
| timebasestruct_t | accu_purr     | accumulated PURR time  |
| timebasestruct_t | accu_spurr    | accumulated SPURR time |

Type for timeslice:

|                                            |                         |
|--------------------------------------------|-------------------------|
| typedef int pm_events_prog_t[MAX_COUNTERS] | array of counted events |
|--------------------------------------------|-------------------------|

The structure **pm\_prog\_mx\_t** contains the following members:

|                  |                    |                                        |
|------------------|--------------------|----------------------------------------|
| unsigned:6       | mode.b.threshold   | threshold value                        |
| unsigned:1       | mode.b.thresh_res  | uses upper threshold multiplier if set |
| unsigned:1       | mode.b.thresh_hres | uses hyper threshold multiplier if set |
| unsigned:1       | mode.b.runlatch    | runlatch enable/disable                |
| unsigned:1       | mode.b.is_group    | is an event group                      |
| unsigned:1       | mode.b.process     | process level group indicator          |
| unsigned:1       | mode.b.hypervisor  | turns hypervisor mode counting on      |
| unsigned:1       | mode.b.kernel      | turns kernel mode counting on          |
| unsigned:1       | mode.b.user        | turns user mode counting on            |
| unsigned:1       | mode.b.count       | counting state                         |
| unsigned:1       | mode.b.proctree    | turns process tree counting on         |
| int              | slice_duration     | duration of each time slice in ms      |
| int              | nb_events_prog     | number of counted event sets           |
| pm_events_prog_t | *events_set;       | array of counted event sets            |

The structure **pm\_prog\_mm\_t** contains the following members:

|           |                |                                             |
|-----------|----------------|---------------------------------------------|
| int       | proctree       | turns process tree counting on              |
| int       | slice_duration | duration of each time slice in ms           |
| int       | nb_set_prog    | number of counted event sets                |
| pm_prog_t | *prog_set;     | array of counted event sets / counting mode |

The structure **pm\_accu\_mx\_t** contains the following members:

|                  |                         |                        |
|------------------|-------------------------|------------------------|
| timebasestruct_t | accu_time               | accumulated time       |
| timebasestruct_t | accu_purr               | accumulated PURR time  |
| timebasestruct_t | accu_spurr              | accumulated SPURR time |
| long long        | accu_data[MAX_COUNTERS] | accumulated data       |

The structure **pm\_data\_mx\_t** contains the following members:

|              |             |                                       |
|--------------|-------------|---------------------------------------|
| pm_ginfo_t   | ginfo       | group information                     |
| int          | nb_accu_mx  | number of data accumulator sets       |
| int          | nb_mx_round | number of loops on all the event sets |
| pm_accu_mx_t | *accu_set   | array of data accumulator sets        |

The structure **pm\_wpar\_ctx\_info\_t** contains the following members:

|                |                            |                                        |
|----------------|----------------------------|----------------------------------------|
| cid_t          | cid                        | WPAR ID                                |
| char           | name[MAXCORRALNAMELEN + 1] | WPAR name                              |
| pm_wp_handle_t | hwpar                      | WPAR opaque handle (unique identifier) |

The following are declared as functions:

## **poll.h File**

### **Purpose**

Defines the structures and flags used by the **poll** subroutine.

## Description

The `/usr/include/sys/poll.h` file defines several structures used by the **poll** subroutine. An array of **pollfd** or **pollmsg** structures or a **pollist** structure specify the file descriptors or pointers and message queues for which the **poll** subroutine checks the I/O status. This file also defines the returned events flags, error returned events flags, device-type flags and input flags used in polling operations.

During a polling operation on both file descriptors and message queues, the *ListPointer* parameter points to a **pollist** structure, which can specify either file descriptors or pointers and message queues. The program must define the **pollist** structure in the following form:

```
struct pollist {
 struct pollfd fdlist[f];
 struct pollmsg msglist[m];
};
```

The **pollfd** structure and the **pollmsg** structure in the **pollist** structure perform the following functions:

| Item              | Description                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>pollfd[f]</b>  | This structure defines an array of file descriptors or file pointers. The <i>f</i> variable specifies the number of elements in the array. |
| <b>pollmsg[m]</b> | This structure defines an array of message queue identifiers. The <i>m</i> variable specifies the number of elements in the array.         |

A **POLLIST** macro is also defined in the **poll.h** file to define the **pollist** structure. The format of the macro is:

```
POLLIST(f, m) Declarator . . . ;
```

The *Declarator* parameter is the name of the variable that is declared as having this type.

The **pollfd** and **pollmsg** structures defined in the **poll.h** file contain the following fields:

| Item          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>fd</b>     | Specifies a valid file descriptor or file pointer to the <b>poll</b> subroutine. If the value of this field is negative, this element is skipped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>msgid</b>  | Specifies a valid message queue ID to the <b>poll</b> subroutine. If the value of this field is negative, this element is skipped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>events</b> | The events being tracked. This is any combination of the following flags:<br><br><b>POLLIN</b><br>Input is present on the file or message queue.<br><br><b>POLLOUT</b><br>The file or message queue is capable of accepting output.<br><br><b>POLLPRI</b><br>An exceptional condition is present on the file or message queue.<br><br><b>revents</b><br>Returned events. This field specifies the events that have occurred. This can be any combination of the events requested by the events field. This field can also contain one of the following flags:<br><br><b>POLLNVAL</b><br>The value specified by the <b>fd</b> field or the <b>msgid</b> field is neither a valid file descriptor or pointer nor the identifier of an accessible message queue.<br><br><b>POLLERR</b><br>An error condition arose on the specified file or message queue. |

## **pthread.h File**

### **Purpose**

Lists threads.

### **Syntax**

```
#include <pthread.h>
```

### **Description**

The **pthread.h** header defines the following symbols:

```
PTHREAD_CANCEL_ASYNCHRONOUS PTHREAD_CANCEL_ENABLE PTHREAD_CANCEL_DEFERRED
PTHREAD_CANCEL_DISABLE PTHREAD_CANCELED PTHREAD_COND_INITIALIZER
PTHREAD_CREATE_DETACHED PTHREAD_CREATE_JOINABLE PTHREAD_EXPLICIT_SCHED
PTHREAD_INHERIT_SCHED PTHREAD_MUTEX_DEFAULT PTHREAD_MUTEX_ERRORCHECK
PTHREAD_MUTEX_NORMAL PTHREAD_MUTEX_INITIALIZER PTHREAD_MUTEX_RECURSIVE
PTHREAD_ONCE_INIT PTHREAD_PRIO_INHERIT PTHREAD_PRIO_NONE
PTHREAD_PRIO_PROTECT PTHREAD_PROCESS_SHARED PTHREAD_PROCESS_PRIVATE
PTHREAD_RWLOCK_INITIALIZER PTHREAD_SCOPE_PROCESS PTHREAD_SCOPE_SYSTEM
```

The **pthread\_attr\_t**, **pthread\_cond\_t**, **pthread\_condattr\_t**, **pthread\_key\_t**, **pthread\_mutex\_t**, **pthread\_mutexattr\_t**, **pthread\_once\_t**, **pthread\_rwlock\_t**, **pthread\_rwlockattr\_t**, and **pthread\_t** types are defined as described in **sys/types.h**.

The following are declared as functions and may also be declared as macros. Function prototypes must be provided for use with an ISO C compiler.

```
int pthread_attr_destroy (pthread_attr_t *);
int pthread_attr_getdetachstate (const pthread_attr_t *, int *);
int pthread_attr_getguardsize (const pthread_attr_t *, size_t *);
int pthread_attr_getinheritsched (const pthread_attr_t *, int *);

```

Inclusion of the **pthread.h** header will make visible symbols defined in the headers **sched.h** and **time.h**.

## **pwd.h File**

### **Purpose**

Describes password structure.

### **Syntax**

```
#include <pwd.h>
```

### **Description**

The **pwd.h** header provides a definition for struct **passwd**, which includes at least the following members:

|       |           |                           |
|-------|-----------|---------------------------|
| char  | *pw_name  | user's login name         |
| uid_t | pw_uid    | numerical user ID         |
| gid_t | pw_gid    | numerical group ID        |
| char  | *pw_dir   | initial working directory |
| char  | *pw_shell | program to use as shell   |

The **gid\_t** and **uid\_t** types are defined as described in **sys/types.h**.

The following are declared as functions and may also be defined as macros. Function prototypes must be provided for use with an ISO C compiler.

```
struct passwd *getpwuid(uid_t);
int getpwnam_r(const char *, struct passwd *, char *, size_t, struct passwd **);
int getpwuid_r(uid_t, struct passwd *, char *, size_t, struct passwd **);
void endpwent(void);
struct passwd *getpwent(void);
void setpwent(void);
```

## **pwdpolicy.h File**

### **Purpose**

Defines the types and manifest constants required to support the **passwdpolicy()** function.

### **Description**

The format of the **pwdpolicy.h** header file shall be similar to the password construction rule attributes as stored in the **/etc/security/user** file, with the exception that named policies do not include the histsize and histexpire attributes. Each file is a sequence of zero or more stanzas with the named policy being the stanza name. Each stanza contains one or more attributes describing the password rules which must be satisfied for a password to be accepted.

Password policy parameters are in the following table.

| <b>Item</b>    | <b>Description</b>                                                                                                                                                                                                                                                                                                                                       |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwp_version    | Specifies the version of the <code>passwd_policy_t</code> structure. The current structure version number is <code>PWP_VERSION_1</code> . Future extensions to this structure will use a different version number.                                                                                                                                       |
| pwp_minage     | The number of seconds as a <code>time32_t</code> between the time a password is modified and the time the password may again be modified. This field is referenced if <code>PWP_TOO_SOON</code> is set in checks.                                                                                                                                        |
| pwp_maxage     | The number of seconds as a <code>time32_t</code> after a password has been modified when it is considered to be expired. This field is referenced if <code>PWP_EXPIRED</code> is set in checks.                                                                                                                                                          |
| pwp_maxexpired | The number of seconds, as a <code>time32_t</code> , after a password has expired when it may no longer be modified. A value of 0 indicates that an expired password may not be changed. A value of -1 indicates that an expired password may be changed after any length of time. This field is referenced if <code>PWP_EXPIRED</code> is set in checks. |
| pwp_minalpha   | The minimum number of characters in the password which must be alphabetic characters, as determined by invoking the <code>isalpha()</code> macro. A value less than or equal to 0 disables this test. This field is referenced if <code>PWP_TOO_FEW_ALPHA</code> is set in checks.                                                                       |
| pwp_minother   | The minimum number of characters in the password which may not be alphabetic characters, as determined by invoking the <code>isalpha()</code> macro. A value less than or equal to 0 disables this test. This field is referenced if <code>PWP_TOO_FEW_OTHER</code> is set in checks.                                                                    |
| pwp_minlen     | The minimum total number of characters in the password. A value less than or equal to 0 disables this test. This field is referenced if <code>PWP_TOO_SHORT</code> is set in checks.                                                                                                                                                                     |

| Item           | Description                                                                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| pwp_maxrepeats | The maximum number of times an individual character may appear in the password. A value less than or equal to 0 disables this test. This field is referenced if PWP_TOO_MANY_REPEATS is set in checks.                    |
| pwp_mindiff    | The minimum number of characters which must be changed between the old password and the new password. A value less than or equal to 0 disables this test. This field is referenced if PWP_TOO_MANY_SAME is set in checks. |

## Example

```
#include <sys/types.h>
/* Name types */
#define PWP_USERNAME 1
#define PWP_SYSTEMPOLICY 2
#define PWP_LOCALPOLICY 3 /* Test flag values */
#define PWP_TOO_SOON 0x0001
#define PWP_EXPIRED 0x0002
#define PWP_TOO_FEW_ALPHA 0x0004
#define PWP_TOO_FEW_OTHER 0x0008
#define PWP_TOO_SHORT 0x0010
#define PWP_TOO_MANY_REPEATS 0x0020
#define PWP_TOO_MANY_SAME 0x0040
#define PWP_IN_DICTIONARY 0x0080
#define PWP_REUSE_PW 0x0100
#define PWP_REUSE_TOO_SOON 0x0200
#define PWP_FAILED_OTHER 0x0400
/* Policy structure version number */
#define PWP_VERSION_1 1
/* Policy structure definition */
typedef struct {
 int pwp_version;
 time32_t pwp_minage;
 time32_t pwp_maxage;
 time32_t pwp_maxexpired;
 int pwp_minalpha;
 int pwp_minother;
 int pwp_minlen;
 int pwp_maxrepeats;
 int pwp_mindiff;
} passwd_policy_t;
```

The maxage, minage, maxexpired, maxrepeats, mindiff, minalpha, minother, and minlen attributes are integers. The dictionlist and pwdchecks attributes are comma-separated lists of filenames. For more information on valid values for attributes, please see [/etc/security/user](#).

## Permissions

Only the root user should have write (w) access.

## Location

[/usr/include/pwdpolicy.h](#)

## sem.h File

### Purpose

Describes the structures that are used by subroutines that perform semaphore operations.

## Description

The `/usr/include/sys/sem.h` file defines the structures that are used by the `semop` subroutine and the `semctl` subroutine to perform various semaphore operations.

The `sem` structure stores the values that the *Commands* parameter of the `semctl` subroutine gets and sets. This structure contains the following fields:

| Item                 | Description                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>semval</code>  | Specifies the operation permission structure of a semaphore. The data type of this field is unsigned short.                    |
| <code>semid</code>   | Specifies the last process that performed a <code>semop</code> subroutine. The data type of this field is <code>pid_t</code> . |
| <code>semncnt</code> | Specifies the number of processes awaiting <code>semval &gt; cval</code> . The data type of this field is unsigned short.      |
| <code>semzcnt</code> | Specifies the number of processes awaiting <code>semval = 0</code> . The data type of this field is unsigned short.            |

The `sembuf` structure stores semaphore information used by the `semop` subroutine. This structure contains the following fields:

### `sem_num`

Specifies a semaphore on which to perform some semaphore operation. The data type of this field is unsigned short.

`sem_op` Specifies a semaphore operation to be performed on the semaphore specified by the `sem_num` field and the *SemaphoreID* parameter of the `semop` subroutine. This value can be a positive integer, a negative integer, or 0:

- i* If the current process has write permission, the positive integer value of this field is added to the value of the `semval` field of the semaphore.
- *i* If the current process has write permission, a negative integer value in this field causes one of the following actions:

If the `semval` field is greater than or equal to the absolute value of the `sem_op` field, the absolute value of the `sem_op` field is subtracted from the value of the `semval` field.

If the `semval` field is less than the absolute value of the `sem_op` field and the `IPC_NOWAIT` flag is set, the `semop` subroutine returns a value of -1 and sets the `errno` global variable to `EAGAIN`.

If the value of the `semval` field is less than the absolute value of the `sem_op` field and the `IPC_NOWAIT` flag is not set, the `semop` subroutine increments the `semncnt` field associated with the specified semaphore and suspends execution of the calling process until one of the following conditions is met:

- The value of the `semval` field becomes greater than or equal to the absolute value of the `sem_op` field. When this occurs, the value of the `semncnt` field associated with the specified semaphore is decremented, the absolute value of the `sem_op` field is subtracted from `semval` value and, if the `SEM_UNDO` flag is set in the `sem_flg` field, the absolute value of the `sem_op` field is added to the *Semadj* value of the calling process for the specified semaphore.
- The semaphore specified by the *SemaphoreID* parameter for which the calling process is awaiting action is removed from the system (see the `semctl` subroutine). When this occurs, the `errno` global variable is set equal to `EIDRM`, and a value of -1 is returned.
- The calling process receives a signal that is to be caught. When this occurs, the value of the `semncnt` field associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in the `sigaction` subroutine.

- 0 If the current process has read permission, a value of 0 in this field causes one of the following actions:
  - If the `semval` field is 0, the `semop` subroutine returns a value of 0.

- If the `semval` field is not equal to 0 and the **IPC\_NOWAIT** flag is set, the `semop` subroutine returns a value of -1 and sets the `errno` global variable to **EAGAIN**.
- If `semval` is not equal to 0 and the **IPC\_NOWAIT** flag is not set, the `semop` subroutine increments the `semzcnt` field associated with the specified semaphore and suspends execution of the calling process until one of the following conditions is met:
  - The value of the `semval` field becomes 0, at which time the value of the `semzcnt` field associated with the specified semaphore is decremented.
  - The semaphore specified by the *SemaphoreID* parameter for which the calling process is awaiting action is removed from the system. When this occurs, the `errno` global variable is set equal to **EIDRM**, and a value of -1 is returned.
  - The calling process receives a signal that is to be caught. When this occurs, the value of the `semzcnt` field associated with the specified semaphore is decremented, and the calling process resumes execution in the manner prescribed in the `sigaction` subroutine.

The data type of the `sem_op` field is short.

#### **sem\_flg**

If the value of this field is not 0 for an operation, the value is constructed by logically ORing one or more of the following values:

##### **SEM\_UNDO**

Specifies whether to modify the *Semadj* values of the calling process.

If this value is set for an operation and the value of the `sem_op` field is a positive integer, the value of the `sem_op` field is subtracted from the *Semadj* value of the calling process.

If this value is set for an operation and the value of the `sem_op` field is a negative integer, the absolute value of the `sem_op` field is added to the *Semadj* value of the calling process. The `exit` subroutine adds the *Semadj* value to the value of the `semval` field of the semaphore when the process terminates.

##### **SEM\_ORDER**

Specifies whether to perform atomically or individually the operations specified by the *SemaphoreOperations* array of the `semop` subroutine. (This flag is valid only when included in the *SemaphoreOperations[0].sem\_flg* parameter, the first operation in the *SemaphoreOperations* array.)

If the **SEM\_ORDER** flag is not set (the default), the specified operations are performed atomically. That is, none of the `semval` values in the array are modified until all of the semaphore operations are completed. If the calling process must wait until some `semval` requirement is met, the `semop` subroutine does so before performing any of the operations. If any semaphore operation would cause an error to occur, none of the operations are performed.

If the **SEM\_ORDER** flag is set, the operations are performed individually in the order that they appear in the array, regardless of whether any of the operations require the process to wait. If an operation encounters an error condition, the `semop` subroutine sets the **SEM\_ERR** flag in the `sem_flg` field of the failing operation; neither the failing operation nor the following operations in the array are performed.

##### **IPC\_NOWAIT**

Specifies whether to wait or to return immediately when the `semval` of a semaphore is not a certain value.

The data type of the `sem_flg` field is short.

The `semid_ds` structure stores semaphore status information used by the `semctl` subroutine and pointed to by the *Buffer* parameter. This structure contains the following fields:

| Item      | Description                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| sem_perm  | Specifies the operation permission structure of a semaphore. The data type of this field is struct <b>ipc_perm</b> .                        |
| sem_nsems | Specifies the number of semaphores in the set. The data type of this field is unsigned short.                                               |
| sem_otime | Specifies the time at which a <b>semop</b> subroutine was last performed. The data type of this field is <b>time_t</b> .                    |
| sem_ctime | Specifies the time at which this structure was last changed with a <b>semctl</b> subroutine. The data type of this field is <b>time_t</b> . |

## sgtty.h File

### Purpose

Provides the terminal interface for the Berkeley line discipline.

### Description

The **sgtty.h** file defines the structures used by ioctl subroutines that apply to terminal files. The structures, definitions, and values in this file are provided for compatibility with the Berkeley user interface for asynchronous communication. Window and terminal size operations use the **winsize** structure, which is defined in the **ioctl.h** file. The **winsize** structure and the ioctl functions that use it are described in **tty Subsystem Overview** in *General Programming Concepts: Writing and Debugging Programs*.

**Note:** Version 4 supports the Berkeley line discipline for compatibility with older applications. However, it is strongly recommended to use the POSIX compliant line discipline, which interface is described in the **termios.h** file.

### Basic sgtty Modes

Basic ioctl functions use the **sgttyb** structure defined in the **sgtty.h** file. This structure contains the following fields:

#### sg\_ispeed

Specifies the input speed of the device. For any particular hardware, impossible speed changes are ignored. Symbolic values in the table are as defined in the **sgtty.h** file.

- |              |                                                                                                                                                                                 |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>B0</b>    | Hangs up. The zero baud rate is used to hang up the connection. If B0 is specified, the 'data terminal ready' signal is dropped. As a result, the line is usually disconnected. |
| <b>B50</b>   | 50 baud.                                                                                                                                                                        |
| <b>B75</b>   | 75 baud.                                                                                                                                                                        |
| <b>B110</b>  | 110 baud.                                                                                                                                                                       |
| <b>B134</b>  | 134.5 baud.                                                                                                                                                                     |
| <b>B150</b>  | 150 baud.                                                                                                                                                                       |
| <b>B200</b>  | 200 baud.                                                                                                                                                                       |
| <b>B300</b>  | 300 baud.                                                                                                                                                                       |
| <b>B600</b>  | 600 baud.                                                                                                                                                                       |
| <b>B1200</b> | 1200 baud.                                                                                                                                                                      |
| <b>B1800</b> | 1800 baud.                                                                                                                                                                      |

**B2400** 2400 baud.

**B4800** 4800 baud.

**B9600** 9600 baud.

**EXTA** External A.

**EXTB** External B.

**sg\_ospeed**

Specifies the output speed of the device. Refer to the description of the **sg\_ispeed** field. The **sg\_ospeed** field has the same values as the **sg\_ispeed** field.

**sg\_erase**

Specifies the erase character. (The default is Backspace.)

**sg\_kill**

Specifies the kill character. (The default is Ctrl-U.)

**sg\_flags**

Specifies how the system treats output. The initial output-control value is all bits clear. The possible output modes are:

**ALLDELAY**

Delays algorithm selection.

**BSDELAY**

Selects backspace delays. Backspace delays are currently ignored. Possible values are BS0 or BS1.

**VTDELAY**

Selects form-feed and vertical-tab delays:

**FF0** Specifies no delay.

**FF1** Specifies one delay of approximately 2 seconds.

**CRDELAY**

Selects carriage-return delays:

**CR0** Specifies no delay.

**CR1** Specifies one delay. The delay lasts approximately 0.08 seconds.

**CR2** Specifies one delay. The delay lasts approximately 0.16 seconds.

**CR3** Specifies one delay. The delay pads lines to be at least 9 characters at 9600 baud.

**TBDELAY**

Selects tab delays:

**TAB0** Specifies no delay.

**TAB1** Specifies one delay. The delay is dependent on the amount of movement.

**TAB2** Specifies one delay. The delay lasts about 0.10 seconds.

**XTABS**

Specifies that tabs are to be replaced by the appropriate number of spaces on output.

**NLDELAY**

Selects the new-line character delays. This is a mask to use before comparing to NL0 and NL1.

**NL0** Specifies no delay.

**NL1** Specifies one delay. The delay is dependent on the current column.

**NL2** Specifies one delay. The delay lasts about 0.10 seconds.

The delay bits specify how long transmission stops to allow for mechanical or other movement when certain characters are sent to the terminal. The actual delays depend on line speed and system load.

#### **EVENP**

Allows even parity on input.

The **EVENP** and **ODDP** flags control both parity checking on input and parity generation on output in COOKED and CBREAK mode (unless the LPASS8 bit is enabled). Even parity is generated on output unless the **ODDP** flag is set and the **EVENP** flag is clear, in which case odd parity is generated. Input characters with the wrong parity, as determined by the **EVENP** and **ODDP** flags, are ignored in COOKED and CBREAK mode.

#### **ODDP**

Allows odd parity on input. Refer to the description of the **EVENP** flag.

**RAW** Indicates the RAW mode, which features a wake up on all characters and an 8-bit interface.

The RAW mode disables all processing except output flushing specified by the **LFLUSHO** bit. The full 8 bits of input are given as soon as they are available; all 8 bits are passed on output. A break condition in the input is reported as a null character. If the input queue overflows in RAW mode, all data in the input and output queues is discarded; this applies to both the new and old drivers.

#### **CRMOD**

Maps a carriage return into a new line on input and outputs a new line as a carriage return and a new line.

**ECHO** Echo (full duplex).

#### **LCASE**

Maps uppercase to lowercase on input and lowercase to uppercase on output on uppercase terminals.

#### **CBREAK**

Enables a half-cooked mode. Programs can read each character as it is typed instead of waiting for a full line. All processing is done except input editing. Character and word erase, line kill, input reprint, and special treatment of the backslash character and the EOT character are disabled.

#### **TANDEM**

Enables automatic flow control (TANDEM mode), which causes the system to produce a stop character (Ctrl-S) when the input queue is in danger of overflowing, and a start character (Ctrl-Q) when the input queue has drained sufficiently. This mode is useful for flow control when the terminal is actually another computer that understands the conventions.

**Note:** The same stop and start characters are used for both directions of flow control. The character specified by the *t\_stopc* field is accepted on input as the character that stops output and is produced on output as the character to stop input. The character specified by the *t\_startc* field is accepted on input as the character that restarts output and is produced on output as the character to restart input.

## **Basic ioctl Operations**

A large number of ioctl commands apply to terminals. Some have the general form:

```
#include <sgtty.h>
ioctl(FileDescriptor, Code, Value)
struct sgttyb *Value;
```

The applicable values for the *Code* parameter are:

| Item     | Description                                                                                                                                                                                 |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCGETP | Fetches the basic parameters associated with the terminal and stores them in the <b>sgttyb</b> structure that is pointed to.                                                                |
| TIOCSETP | Sets the parameters according to the <b>sgttyb</b> structure that is pointed to. The interface delays until output stops, then throws away any unread characters before changing the modes. |
| TIOCSETN | Has the same effect as the <b>TIOCSETP</b> value but does not delay or flush input. Input is not preserved, however, when changing to or from the RAW mode.                                 |

For the following codes, the *Value* parameter is ignored:

| Item     | Description                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCEXCL | Sets exclusive-use mode; no further opens are permitted until the file is closed.                                                                       |
| TIOCNXCL | Turns off exclusive-use mode.                                                                                                                           |
| TIOCHPCL | When the file is closed for the last time, hangs up the terminal. This is useful when the line is associated with a modem used to place outgoing calls. |

For the following code, the *Value* parameter is a pointer to an integer.

| Item      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCFLUSH | If the integer pointed to by the <i>Value</i> parameter has a zero value, all characters waiting in input or output queues are flushed. Otherwise, the value of the integer applies to the FREAD and FWRITE bits defined in the <b>fcntl.h</b> file. If the FREAD bit is set, all characters waiting in input queues are flushed. If the FWRITE bit is set, all characters waiting in output queues are flushed.<br><b>Note:</b> The FREAD and FWRITE bits cannot be used unless the <b>_KERNEL</b> flag is set. |

In the following codes, the argument is 0 unless specified otherwise:

| Item      | Description                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCSTI   | The <i>Value</i> parameter points to a character that the system pretends has been typed on the terminal.                                                                               |
| TIOCSBRK  | The break bit is set in the terminal.                                                                                                                                                   |
| TIOCCBRK  | The break bit is cleared.                                                                                                                                                               |
| TIOCSDTR  | Data terminal ready is set.                                                                                                                                                             |
| TIOCCDTR  | Data terminal ready is cleared.                                                                                                                                                         |
| TIOCSTOP  | Output is stopped as if the stop character had been typed.                                                                                                                              |
| TIOCSTART | Output is restarted as if the start character had been typed.                                                                                                                           |
| TIOCGPGRP | The <i>Value</i> parameter is a pointer to an integer into which is placed the process group ID of the process group for which this terminal is the control terminal.                   |
| TIOCSPGRP | The <i>Value</i> parameter is a pointer to an integer which is the value to which the process group ID for this terminal will be set.                                                   |
| TIOCOUTQ  | Returns in the integer pointed to by the <i>Value</i> parameter the number of characters queued for output to the terminal.                                                             |
| TIONREAD  | Returns in the integer pointed to by the <i>Value</i> parameter the number of characters immediately readable from the argument descriptor. This works for files, pipes, and terminals. |

## Uppercase Terminals

If the **LCASE** output-mode bit is set, all uppercase letters are mapped into the corresponding lowercase letter. The uppercase letter can be generated by preceding it with a \ (backslash). Uppercase letters are preceded by a backslash when they are output. In addition, the following escape sequences can be generated on output and accepted on input:

| For       | Use |
|-----------|-----|
| ` (grave) | \`  |
|           | \!  |
| ~         | \^  |
| {         | \(  |
| }         | \)  |

To deal with terminals that do not understand that the ~ (tilde) has been made into an ASCII character, the LTILDE bit can be set in the local-mode word. When the LTILDE bit is set, the ~ (tilde) character will be replaced with the ` (grave) character on output.

## Special Characters

A **tchars** structure associated with each terminal specifies special characters for both the old and new terminal interfaces. This structure is defined in the **ioctl.h** file, for which the **sgtty.h** file contains an **#include** statement. The **tchars** structure contains the following fields:

| Item            | Description                                                                                                                                                                                      |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t_intrc</b>  | The interrupt character (Ctrl-C, by default) generates a <b>SIGINT</b> signal. This is the normal way to stop a process that is no longer needed or to regain control in an interactive program. |
| <b>t_quitc</b>  | The quit character (Ctrl-\, by default) generates a <b>SIGQUIT</b> signal. This is used to end a program and produce a core image, if possible, in a <b>core</b> file in the current directory.  |
| <b>t_startc</b> | The start-output character (Ctrl-Q, by default).                                                                                                                                                 |
| <b>t_stopc</b>  | The stop-output character (Ctrl-S, by default).                                                                                                                                                  |
| <b>t_eofc</b>   | The end-of-file character (Ctrl-D, by default).                                                                                                                                                  |
| <b>t_brkc</b>   | The input delimiter (-1, by default). This character acts like a newline in that it ends a line, is echoed, and is passed to the program.                                                        |

The stop and start characters can be the same to produce a toggle effect. The applicable ioctl functions are:

| Item            | Description                                                           |
|-----------------|-----------------------------------------------------------------------|
| <b>TIOCGETC</b> | Gets the special characters and puts them in the specified structure. |
| <b>TIOCSETC</b> | Sets the special characters to those given in the structure.          |

## Local Mode

Associated with each terminal is a local-mode word. The bits of the local-mode word are:

| Item           | Description                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <b>LCRTBS</b>  | Backspaces on erase rather than echoing erase.                                                                   |
| <b>LPRTERA</b> | Printing terminal erase mode.                                                                                    |
| <b>LCRTERA</b> | Erases character echoes as Backspace-Space-Backspace.                                                            |
| <b>LTILDE</b>  | Converts ~ (tilde) to ` (grave) on output (for terminals that do not recognize the tilde as an ASCII character). |
| <b>LMDMBUF</b> | Stops and starts output when carrier drops.                                                                      |
| <b>LLITOUT</b> | Suppresses output translations.                                                                                  |
| <b>LTOSTOP</b> | Sends a <b>SIGTTOU</b> signal for background output.                                                             |
| <b>LFLUSHO</b> | Output is being flushed.                                                                                         |
| <b>LNOHANG</b> | Do not send hang up when carrier drops.                                                                          |
| <b>LCRTKIL</b> | Backspace-Space-Backspace to erase the entire line on line kill.                                                 |
| <b>LPASS8</b>  | Passes all 8 bits through on input, in any mode.                                                                 |
| <b>LCTLECH</b> | Echoes input control characters as Ctrl-X, delete as Ctrl-?.                                                     |
| <b>LPENDIN</b> | Retypes pending input at next read or input character.                                                           |
| <b>LDECCTQ</b> | Only Ctrl-Q restarts output after a Ctrl-S.                                                                      |
| <b>LNOFLSH</b> | Inhibits flushing of pending I/O when an interrupt character is typed.                                           |

The following ioctl functions operate on the local-mode word structure:

| Item     | Description                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------------------|
| TIOCLBIS | The <i>Value</i> parameter is a pointer to an integer whose value is a mask containing the bits to be set in the local-mode word.     |
| TIOCLBIC | The <i>Value</i> parameter is a pointer to an integer whose value is a mask containing the bits to be cleared in the local-mode word. |
| TIOCLSET | The <i>Value</i> parameter is a pointer to an integer whose value is stored in the local-mode word.                                   |
| TIOCLGET | The <i>Value</i> parameter is a pointer to an integer into which the current local-mode word is placed.                               |

## Local Special Characters

The **Itchars** structure associated with each terminal defines control characters for the new terminal driver. This structure contains the following fields:

| Item     | Description                                                                                                                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| t_suspc  | The suspend-process character (Ctrl-Z, by default). This sends a <b>SIGTSTP</b> signal to suspend the current process group. This character is recognized during input.                                                                                            |
| t_dsuspc | The delayed suspend-process character (Ctrl-Y, by default). This sends a <b>SIGTSTP</b> signal to suspend the current process group. This character is recognized when the process attempts to read the control character rather than when the character is typed. |
| t_rprntc | The reprint line-control character (Ctrl-R, by default). This reprints all characters that are preceded by a new-line character and have not been read.                                                                                                            |
| t_flushc | The flush-output character (Ctrl-O, by default). This flushes data that is written but not transmitted.                                                                                                                                                            |
| t_werasc | The word-erase character (Ctrl-W, by default). This erases the preceding word. This does not erase beyond the beginning of the line.                                                                                                                               |
| t_lnextc | The literal-next character (Ctrl-V, by default). This causes the special meaning of the next character to be ignored so that characters can be input without being interpreted by the system.                                                                      |

The following ioctl functions, which use the **Itchars** structure, are supported by the terminal interface for the definition of local special characters for a terminal:

| Item     | Description                                                                                                                                                        |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCSLTC | Sets local characters. The argument to this function is a pointer to an <b>Itchars</b> structure, which defines the new local special characters.                  |
| TIOCGLTC | Sets local characters. The argument to this function is a pointer to an <b>Itchars</b> structure into which is placed the current set of local special characters. |

The **winsize** structure and the ioctl functions that use it are described in the discussion of the **tty** common code in "tty Subsystem Overview" in *General Programming Concepts: Writing and Debugging Programs*.

## File

| Item     | Description                                                                   |
|----------|-------------------------------------------------------------------------------|
| /dev/tty | The <b>tty</b> special file, which is a synonym for the controlling terminal. |

# shm.h File

## Purpose

Describes the structures that are used by the subroutines that perform shared memory operations.

## Syntax

```
#include <sys/shm.h>
```

## Description

The **shm.h** header file defines the following symbolic constants, types, and structures:

### Types:

```
typedef unsigned short shmat_t;
```

### Symbolic Constants:

|               |                                                  |
|---------------|--------------------------------------------------|
| SHMLBA        | segment low boundary address multiple            |
| SHMLBA_EXTSHM | SHMLBA value when environment variable EXTSHM=ON |
| SHM_RDONLY    | attach read-only (else read-write)               |
| SHM_RND       | round attach address to SHMLBA                   |
| SHM_MAP       | map a file instead of share a segment            |
| SHM_FMAP      | fast file map                                    |
| SHM_COPY      | deferred update                                  |
| SHM_R         | read permission                                  |
| SHM_W         | write permission                                 |
| SHM_DEST      | destroy segment when # attached = 0              |
| ZERO_MEM      | for disclaim                                     |
| SHMHISEG      | highest shared memory segment allowed            |
| SHMLOSEG      | lowest shared memory segment allowed             |
| NSHMSEGS      | number of shared memory segments allowed         |

There is a shared mem id data structure for each shared memory and mapped file segment in the system.

## Structures

The structure **shmid\_ds** contains the following members:

|                 |             |                                            |
|-----------------|-------------|--------------------------------------------|
| struct ipc_perm | shm_perm    | operation permission struct                |
| size_t          | shm_segsz   | size of segment in bytes                   |
| pid_t           | shm_lpid    | process ID of last shared memory operation |
| pid_t           | shm_cpid    | pid of creator                             |
| shmat_t         | shm_nattach | number of current attaches                 |
| time_t          | shm_atime   | last <b>shmat</b> time                     |
| time_t          | shm_dtime   | time of last <b>shmdt</b>                  |
| time_t          | shm_ctime   | time of last change by <b>shmctl</b>       |

The structure **shminfo** contains the following members:

|              |        |                                |
|--------------|--------|--------------------------------|
| unsigned int | shmmax | max shared memory segment size |
| int          | shmin  | min shared memory segment size |
| int          | shmmni | # of shared memory identifiers |

The types **pid\_t**, **time\_t**, **key\_t**, and **size\_t** are defined as described in **<sys/types.h>**. The following are declared as functions:

```
void *shmat(int, const void *, int);
int shmctl(int, int, struct shmid_ds *);
int shmdt(const void *);
int shmget(key_t, size_t, int);
```

In addition, all of the symbols from **<sys/ipc.h>** will be defined when this header is included.

## spc.h File

### Purpose

Defines external interfaces provided by the System Resource Controller (SRC) subroutines.

### Description

The **/usr/include/spc.h** file defines data structures and symbolic constants that are used when calling the SRC subroutines. All subsystems that are controlled by the SRC via sockets or message queues should include this header file.

The **scrreq** data structure in the **spc.h** file defines the format of requests sent to a subsystem by the **srcmstr** daemon. This format is also used by SRC subroutines that send requests to the **srcmstr** daemon.

The **scrreq** data structure contains the following fields:

| Item          | Description                                                                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>mtype</b>  | The message type for the message queue. This field should be included only for message queue subsystems. Programs should be compiled with the <b>-DSRCBYQUEUE</b> flag to generate the <b>mtype</b> field. |
| <b>srchdr</b> | The SRC header that must be included in all packets sent to and received from an SRC subsystem.                                                                                                            |
| <b>subreq</b> | The request to be processed by the SRC subsystem.                                                                                                                                                          |

The **srchdr** data structure in the **scrreq** data structure contains the return address that is needed to reply to the request. The **srcrrqs** subroutine can be used to extract this information from the request. The **srchdr** data structure is also part of the reply structure returned by a subsystem.

The **srchdr** data structure contains the following fields:

| Item            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>retaddr</b>  | The return address                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>dversion</b> | The SRC packet version.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>cont</b>     | The continuation indicator. The possible values are:<br><br><b>NEWREQUEST</b><br>Used in a request to the <b>srcmstr</b> daemon.<br><br><b>CONTINUED</b><br>Used in a reply returned by a subsystem, indicating another packet follows.<br><br><b>STATCONTINUED</b><br>Used in a status reply returned by a subsystem, indicating another packet follows.<br><br><b>END</b> Used in a request seen by a subsystem or the last packet in reply sequence. |

The **subreq** data structure contains the request to be processed by the subsystem. This same structure is used when calling the **srcsrqt** subroutine to send a request to a subsystem. The **srcsrqt** subroutine formats the required **srchdr** structure. The request is processed by the **srcmstr** daemon and passed on to a subsystem.

The **subreq** data structure contains the following fields:

| Item    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| object  | Defines the object on which to act. The possible values are either the <b>SUBSYSTEM</b> constant, or a subserver code point. If the object is a subsystem, the value of this field is the <b>SUBSYSTEM</b> constant as defined in the <b>spc.h</b> file and the <b>objname</b> field contains either a null value or the subsystem name. If the object is a subserver, the <b>object</b> field value is the code point from the subserver object definition, and the <b>objname</b> field is subsystem-defined. The <b>objname</b> field can be null, the subserver name, or the subserver process ID. The <b>object</b> value for the subserver cannot equal the value reserved for the subsystem. |
| action  | SRC action to perform. Possible types are:<br><br><b>START</b><br><br><b>STOP</b><br><br><b>STATUS or SRCSTATUS</b><br><br><b>TRACE</b><br><br><b>REFRESH</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|         | The values 0-255 are reserved for use by the SRC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| parm1   | Modifies the SRC action type by indicating a variable associated with an action. This field is used in a different manner by each of the actions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| parm2   | Modifies the SRC action type by indicating a variable associated with an action. This field is used in a different manner by each of the actions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| objname | Name of the object that the request applies to. This can be a subsystem name, a subserver object, or a subserver process ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The **srcrep** and **statrep** structures in the **spc.h** file define formats for the replies returned by a subsystem. For more information, see the **srcsrpy** subroutine.

The **srcrep** data structure must be used for replies to start, stop, refresh, and trace requests. It contains the following fields:

| Item     | Description                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srchdr   | Specifies the SRC request/reply ( <b>srchdr</b> ) header.                                                                                                             |
| svrreply | A reply structure containing the following fields:                                                                                                                    |
| rtncode  | Subsystem response to the request. This response is negative on error or subsystem unique message.                                                                    |
| objtype  | The object type. This is one of the following: <ul style="list-style-type: none"><li>• <b>SUBSYSTEM</b></li><li>• Subserver code point</li><li>• Error code</li></ul> |
| objtext  | Text description.                                                                                                                                                     |
| objname  | Name of the object (subsystem/subserver).                                                                                                                             |
| rtnmsg   | Subsystem unique message.                                                                                                                                             |

The **statrep** data structure is used for replies to status requests. It contains the following fields:

| Item     | Description                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| srchdr   | Specifies the SRC request/reply ( <b>srchdr</b> ) header.                                                                                                             |
| statcode | A status structure containing the following fields. There may be an array of these structures. This structure contains the following fields:                          |
| objtype  | The object type. This is one of the following: <ul style="list-style-type: none"><li>• <b>SUBSYSTEM</b></li><li>• Subserver code point</li><li>• Error code</li></ul> |
| status   | Status code. See the <b>spc.h</b> file for the symbolic constants that may be used with this field.                                                                   |
| objtext  | Text description.                                                                                                                                                     |
| objname  | Name of the object (subsystem/subserver) this reply belongs to.                                                                                                       |

The **spc.h** file also defines the following constants that are useful in communicating with the **srcmstr** daemon:

| Item             | Description                                                                         |
|------------------|-------------------------------------------------------------------------------------|
| <b>SRCNAMESZ</b> | The maximum length of an SRC object name (30 bytes, including the null terminator). |
| <b>SRCPKTMAX</b> | The maximum packet size (8192 bytes).                                               |

There are also SRC subroutines to manage SRC objects, including subsystems and subservers. The **spc.h** file defines certain symbolic constants which are useful when defining object attributes. The following SRC object descriptors are defined in the **/usr/include/sys/srcobj.h** file:

| Item            | Description |
|-----------------|-------------|
| Respawn action: |             |

**RESPAWN=1**

**ONCE=2**

| Item             | Description |
|------------------|-------------|
| Contact options: |             |

**SRCIPC=1**

**SRCSIGNAL=2**

**SRC SOCKET=3**

| Item                                           | Description |
|------------------------------------------------|-------------|
| Multiple instances of a subsystem are allowed: |             |

**SRCYES=1**

**SRCCNO=0**

| Item                                               | Description |
|----------------------------------------------------|-------------|
| Display subsystem status under certain conditions: |             |

**SRCYES=1**

**SRCCNO=0**

| Item                | Description |
|---------------------|-------------|
| Default time limit: |             |

**TIMELIMIT=20 (seconds)**

The **spc.h** file also includes the **/usr/include/srcerrno.h** file, which contains symbolic constants for the errors returned by the SRC library subroutines. The **src\_err\_msg** subroutine can be used to retrieve the corresponding error message.

## SRC Request Structure Example

The following program excerpt is an example of the SRC request (**srcreq**) structure.

```

struct srcreq
{
 long mtype; /*Contains the message type in the IPC buffer*/
 /*This field is included if IPC is used and a
 message queue is expected*/
 struct srchdr srchdr; /*src header table entry - defined below*/
 struct subreq subreq; /*the request passed to the subsystem*/
};

struct srchdr /*srchdr structure is used by SRC routines*/
/*subsystems are not responsible for setting \
 this*/
{
 struct sockaddr_un retaddr;
 short dversion; /*the version of the data format*/
 short cont; /*used to indicate message is continued*/
};

struct subreq
{
 short object; /*object to act on*/
 short action; /*action START, STOP, STATUS,TRACE,REFRESH*/
 short parm1; /* */
 short parm2; /* */
 char objname[SRCNAMES]; /*object name*/
};

```

System Resource Controller (SRC) Overview for Programmers

## srcobj.h File

### Purpose

Defines object structures used by the System Resource Controller (SRC) subsystem.

### Description

The **/usr/include/sys/srcobj.h** header file contains the structures defining SRC objects. The **SRCSUBSYS** structure contains the following fields:

| Item       | Description                                                                                                              |
|------------|--------------------------------------------------------------------------------------------------------------------------|
| subsysname | String that contains the subsystem name. This string can contain 30 bytes, including the null terminator.                |
| synonym    | String that contains the subsystem synonym. This string can contain 30 bytes, including the null terminator.             |
| cmdargs    | String that contains the subsystem command arguments. This string can contain 200 bytes, including the null terminator.  |
| path       | String that contains the path to the executable files. This string can contain 200 bytes, including the null terminator. |
| uid        | User ID for the subsystem.                                                                                               |
| auditid    | Audit ID for the subsystem. This value is supplied by the system and cannot be changed by an SRC subroutine.             |
| standin    | String that contains the path for standard input. This string can contain 200 bytes, including the null terminator.      |
| standout   | String that contains the path for standard output. This string can contain 200 bytes, including the null terminator.     |
| standerr   | String that contains the path for standard error. This string can contain 200 bytes, including the null terminator.      |
| action     | Respawn action. The value of this field can be either <b>ONCE</b> or <b>RESPAWN</b> .                                    |
| multi      | Multiple instance support. The value of this field can be either <b>SRCYES</b> or <b>SRCNO</b> .                         |

| <b>Item</b> | <b>Description</b>                                                                                                                                                                                     |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| contact     | Contact type. The value of this field indicates either a signal ( <b>SRCSIGNAL</b> ), a message queue ( <b>SRCIPC</b> ), or a socket ( <b>SRCSOCKET</b> ).                                             |
| srvkey      | IPC message queue key.                                                                                                                                                                                 |
| svrtype     | IPC message type (mtype) for the subsystem.                                                                                                                                                            |
| priority    | Nice value, a number from 1 to 40.                                                                                                                                                                     |
| signorm     | Stop normal signal.                                                                                                                                                                                    |
| sigforce    | Stop force signal.                                                                                                                                                                                     |
| display     | Display inactive subsystem on all or group status. The value of this field can be either <b>SRCYES</b> or <b>SRCNO</b> .                                                                               |
| waittime    | Stop cancel time to wait before sending a <b>SIGKILL</b> signal to the subsystem restart time period. (A subsystem can be restarted only twice in this time period if it does not terminate normally.) |
| grpname     | String that contains the group name of the subsystem. This string can contain 30 bytes, including the null terminator.                                                                                 |

The **SRCSubsvr** structure contains the following fields:

| <b>Item</b> | <b>Description</b>                                                                                               |
|-------------|------------------------------------------------------------------------------------------------------------------|
| sub_type    | String that contains the type of the subsystem. This string can contain 30 bytes, including the null terminator. |
| subsysname  | String that contains the subsystem name. This string can contain 30 bytes, including the null terminator.        |
| sub_code    | Subsystem code. This is a decimal number.                                                                        |

The **SRCCnotify** structure contains the following fields:

| <b>Item</b>  | <b>Description</b>                                                                                                                                             |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| notifyname   | String that contains the name of the subsystem or group to which the notify method applies. This string can contain 30 bytes, including the null terminator.   |
| notifymethod | String that is executed when the SRC detects abnormal termination of the subsystem or group. This string can contain 256 bytes, including the null terminator. |

The possible values indicated for the fields are predefined.

## stat.h File

### Purpose

Defines the data structures returned by the stat family of subroutines.

### Description

The **stat** data structure in the **/usr/include/sys/stat.h** file returns information for the **stat**, **fstat**, **lstat**, **statx**, and **fstatx** subroutines.

The **stat** data structure contains the following fields:

| Item       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| st_dev     | Device that contains a directory entry for this file.                                                                                                                                                                                                                                                                                                                                                                                              |
| st_ino     | Index of this file on its device. A file is uniquely identified by specifying the device on which it resides and its index on that device.                                                                                                                                                                                                                                                                                                         |
| st_mode    | File mode. The possible file mode values are given in the description of the <i>/usr/include/sys/mode.h</i> file.                                                                                                                                                                                                                                                                                                                                  |
| st_nlink   | Number of hard links (alternate directory entries) to the file created using the <b>link</b> subroutine.                                                                                                                                                                                                                                                                                                                                           |
| st_access  | Field is not implemented. All bits are returned as zero.                                                                                                                                                                                                                                                                                                                                                                                           |
| st_size    | Number of bytes in a file (including any holes). This field also defines the position of the end-of-file mark for the file. The end-of-file mark is updated only by subroutines, for example the <b>write</b> subroutine. If the file is mapped by the <b>shmat</b> subroutine and a value is stored into a page past the end-of-file mark, that mark will be updated to include this page when the file is closed or forced to permanent storage. |
| st_rdev    | ID of the device. This field is defined only for block or character special files.                                                                                                                                                                                                                                                                                                                                                                 |
| st_atime   | Time when file data was last accessed. st_atime and st_atime_n taken together represent the last file access time in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                            |
| st_atime_n | Time when file data was last accessed. st_atime and st_atime_n taken together represent the last file access time in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                            |
| st_mtime   | Time when file data was last modified. st_mtime and st_mtime_n taken together represent the last file modification time in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                      |
| st_mtime_n | Time when file data was last modified. st_mtime and st_mtime_n taken together represent the last file modification time in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                      |
| st_ctime   | Time when the file status was last changed. st_ctime and st_ctime_n taken together represent the last file status change in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                     |
| st_ctime_n | Time when the file status was last changed. st_ctime and st_ctime_n taken together represent the last file status change in number of seconds and nanoseconds since the epoch.                                                                                                                                                                                                                                                                     |
| st_blksize | Size, in bytes of each block of the file.                                                                                                                                                                                                                                                                                                                                                                                                          |
| st_blocks  | Number of blocks actually used by the file (measured in the units specified by the <b>DEV_BSIZE</b> constant).                                                                                                                                                                                                                                                                                                                                     |
| st_gen     | Generation number of this i-node.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| st_type    | Type of the v-node for the object. This is one of the following values, which are defined in the <i>/usr/include/sys/vnode.h</i> file:                                                                                                                                                                                                                                                                                                             |
|            | <b>VNON</b> Unallocated object; this should not occur                                                                                                                                                                                                                                                                                                                                                                                              |

|            | <b>VMPC</b> Multiplexed character device.                                                                                                                                                                                                                                                                                                                                                                                                          |
| st_vfs     | Virtual file system (VFS) ID, which identifies the VFS that contains the file. By comparing this value with the VFS numbers returned by the <b>mntctl</b> subroutine, the name of the host where the file resides can be identified.                                                                                                                                                                                                               |
| st_vfstype | File-system type, as defined in the <i>/usr/include/sys/vmount.h</i> file.                                                                                                                                                                                                                                                                                                                                                                         |
| st_flag    | Flag indicating whether the file or the directory is a virtual mount point. This flag can have the following values:                                                                                                                                                                                                                                                                                                                               |
|            | <b>FS_VMP</b><br>Indicates that the file is a virtual mount point.                                                                                                                                                                                                                                                                                                                                                                                 |
|            | <b>FS_MOUNT</b><br>Indicates that the file is a virtual mount point.                                                                                                                                                                                                                                                                                                                                                                               |
|            | <b>FS_REMOTE</b><br>Indicates that the file resides on another machine.                                                                                                                                                                                                                                                                                                                                                                            |
| st_uid     | File owner ID.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| st_gid     | File group ID.                                                                                                                                                                                                                                                                                                                                                                                                                                     |

The **stat64** data structure in the */usr/include/sys/stat.h* file returns information for the **stat64**, **fstat64**, and **lstat64** subroutines. The **stat64** structure contains the same fields as the **stat** structure, with the exception of the following field:

| Item    | Description                                                                                                                                                                                                         |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| st_size | Number of bytes in a file. The <b>st_size</b> field is a 64-bit quantity, allowing file sizes greater than <b>OFF_MAX</b> . The <b>st_size</b> field of the <b>stat64</b> structure is of the type <b>off64_t</b> . |

For remote files, the **st\_atime**, **st\_mtime**, and **st\_ctime** fields contain the time at the server.

The value of the **st\_atime** field can be changed by the following subroutines:

- **read**, **readx**, **readyv**, **readvx**
- **readlink**
- **shmdt**
- **utime**, **utimes**

The values of the **st\_ctime** and **st\_mtime** fields can be set by the following subroutines:

- **write**, **writex**, **writev**, **writevx**
- **open**, **openx**, **creat**
- **link**
- **symlink**
- **unlink**
- **mknod**
- **mkdir**
- **rmdir**
- **rename**
- **truncate**, **ftruncate**
- **utime**, **utimes**

In addition, the **shmdt** subroutine can change the **st\_mtime** field, and the **chmod**, **fchmod**, **chown**, **chownx**, **fchown**, and **fchownx** subroutines can change the **st\_ctime** field.

Because they can create a new object, the **open**, **openx**, **creat**, **symlink**, **mknod**, **mkdir**, and **pipe** subroutines can set the **st\_atime**, **st\_ctime**, and **st\_mtime** fields.

## **statfs.h File**

### **Purpose**

Describes the structure of the statistics returned by the **statfs**, **fstatfs**, or **ustat** subroutine.

## Description

The **statfs** and **fstatfs** subroutines return information on a mounted (virtual) file system in the form of a **statfs** structure. The **/usr/include/sys/statfs.h** file describes the **statfs** structure, which contains the following fields:

| Item             | Description                                                                                                                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>f_version</b> | Version number of the <b>statfs</b> structure. This value is currently 0.                                                                                                                                                                             |
| <b>f_length</b>  | Length of the buffer that contains the returned information. This value is currently 0.                                                                                                                                                               |
| <b>f_type</b>    | Type of information returned. This value is currently 0.                                                                                                                                                                                              |
| <b>f_bsize</b>   | Optimal block size of the file system.                                                                                                                                                                                                                |
| <b>f_blocks</b>  | Total number of blocks in the system.                                                                                                                                                                                                                 |
| <b>f_bfree</b>   | Number of free blocks in the file system. The size of a free block is given in the <b>f_bsize</b> field.                                                                                                                                              |
| <b>f_bavail</b>  | Number of free blocks available to a nonroot user.                                                                                                                                                                                                    |
| <b>f_files</b>   | Total number of file nodes in the file system.                                                                                                                                                                                                        |
| <b>f_ffree</b>   | Number of free file nodes in the file system.                                                                                                                                                                                                         |
| <b>f_fsid</b>    | File system ID.                                                                                                                                                                                                                                       |
| <b>f_vfstype</b> | Type of this virtual file system. Possible values are:<br><br><b>MNT_JFS</b><br>Journaled File System (JFS) of the operating system<br><b>MNT_NFS</b><br>SUN network file system<br><b>MNT_CDROM</b><br>CD-ROM file system.<br><br><b>f_fsize</b><br> |

**Note:** Fields that are not defined for a particular file system are set to a value of -1.

The **ustat** system returns information on a mounted file system in the form of a **ustat** structure. The **ustat** structure, which is defined in the **/usr/include/ustat.h** file, contains the following fields:

| Item    | Description                                                                                                                                                                          |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| f_tfree | Total number of free blocks in the file system. The size of a free block is given in by the <b>UBSIZE</b> constant. See the <b>param.h</b> file for a description of <b>UBSIZE</b> . |
| f_inode | Number of free i-nodes in the file system.                                                                                                                                           |
| f_fname | File system name.                                                                                                                                                                    |
| f_fpack | File system pack name.                                                                                                                                                               |

## Files

| Item     | Description                       |
|----------|-----------------------------------|
| statfs.h | Path to the <b>statfs.h</b> file. |
| ustat.h  | Path to the <b>ustat.h</b> file.  |

statfs, fstatfs, or ustat subroutine

## statvfs.h File

### Purpose

Describes the structure of the statistics that are returned by the **statvfs** subroutines and **fsatvfs** subroutines.

### Description

The **statvfs** subroutines and **fsatvfs** subroutines return information on a mounted filesystem in the form of statvfs. The **/usr/include/sys/statvfs.h** file describes the following fields in the **statvfs** subroutine:

| Item       | Description                                                                                 |
|------------|---------------------------------------------------------------------------------------------|
| f_bsize    | Preferred file system block size                                                            |
| f_frsize   | Fundamental file system block size                                                          |
| f_block    | Total number of block f_frsize in the file system.                                          |
| f_bfree    | Total number of free blocks of f_frsize in the file system.                                 |
| f_bavail   | Total number of available blocks of f_frsize that can be used by users without root access. |
| f_files    | Total number of file nodes in the file system                                               |
| f_ffree    | Number of free file nodes in the file system.                                               |
| f_favail   | Number of free file nodes that can be user without root access.                             |
| f_fsid     | File system ID.                                                                             |
| f_basetype | File system type name                                                                       |
| f_flag     | File system flags:                                                                          |
|            | <b>ST_RDONLY</b>                                                                            |
|            | File system is mounted read only                                                            |
|            | <b>ST_NOSUID</b>                                                                            |
|            | File system does not support set used ID file modes                                         |
|            | <b>ST_NODEV</b>                                                                             |
|            | Device opens are not allowed through mounts.                                                |
| f_namemax  | Maximum length of a component name for this file system                                     |
| f_fstr     | File system specific string.                                                                |

The following prototypes also appear in the **/usr/include/sys/statvfs.h** file:

```
extern int statvfs(const char *, struct statvfs *);
```

```
extern int fsatvfs(int, struct statvfs *);
```

## systemcfg.h File

### Purpose

Defines the `_system_configuration` structure.

### Description

The `systemcfg.h` file defines the `_system_configuration` structure. This is a global structure that identifies system characteristics. The `system_configuration` structure is provided in read-only system memory. The attributes in the `_system_configuration` structure have the following values:

| Item                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>architecture</code> | Identifies the processor architecture. Valid values for Version 4 are:<br><br><b>POWER_RS</b><br>Indicates a POWER® family machine.<br><br><b>POWER_PC</b><br>Indicates a POWER processor-based.<br><br><b>implementation</b><br>Identifies the specific version of the processor. Each implementation is assigned a unique bit to allow for efficient checking of implementation sets. The following are examples of valid values (the header file contains more values):<br><br><b>POWER_RS1</b><br><b>POWER_RS2</b><br><b>POWER_RSC</b><br><b>POWER_601</b><br><br>Two special values are also defined: <b>POWER_RS_ALL</b> and <b>POWER_PC_ALL</b> . These labels are defined as the bit OR of all members of their architecture.<br><br><b>version</b><br>Identifies the central processing unit (CPU) version number. The following are examples of valid values (the header file contains more values):<br><br><b>PV_RS1</b> Identifies a POWER family RS1 machine.<br><b>PV_RS2</b> Identifies a POWER family RS2 machine.<br><br><b>PV_RS2G</b><br>Identifies a POWER family RS2 machine with graphics assist.<br><br><b>PV_RSC</b><br>Identifies a POWER family RSC machine.<br><br><b>PV_601</b> Identifies a PowerPC 601 RISC Microprocessor machine.<br><br><b>width</b><br>Contains the processor data-word size. Valid values are 32 or 64. This value is the maximum data-word size and should not be confused with the current execution mode.<br><br><b>ncpus</b><br>Identifies the number of CPUs active on a machine. Uniprocessor (UP) machines are identified by a 1. Values greater than 1 indicate multiprocessor (MP) machines.<br><br><b>cache_attr</b><br>Specifies the cache attributes. Bit 31 determines if the cache is present. If this bit is 1, the cache is present. If bit 31 is 0, then no cache is present and all other cache characteristics are 0. Bit 30 indicates the type of cache. If bit 30 is 1, the cache is combined. Otherwise, if bit 30 is 0 the instruction and data caches are separate.<br><br><b>icache_size</b><br>Contains the L1 instruction-cache size in bytes. For combined caches, this value is the total cache size.<br><br><b>dcache_size</b><br>Contains the size of the L1 data-cache size in bytes. For combined caches this the total cache size.<br><br><b>icache_asc</b><br>Contains the L1 instruction-cache associativity. For a combined cache, this is the combined caches' associativity.<br><br><b>dcache_asc</b><br>Contains the L1 data-cache associativity. For a combined cache, this is the combined caches' associativity. |

| Item                 | Description                                                                                                                                                                                                                                                                                                                |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>icache_line</b>   | Contains the line size in bytes of the L1 instruction cache.                                                                                                                                                                                                                                                               |
| <b>dcache_line</b>   | Contains the line size in bytes of L1 data cache.                                                                                                                                                                                                                                                                          |
| <b>L2_cache_size</b> | Contains the size of the L2 cache in bytes. A value of 0 indicates no L2 cache is present.                                                                                                                                                                                                                                 |
| <b>L2_cache_asc</b>  | Identifies the associativity of the L2 cache.                                                                                                                                                                                                                                                                              |
| <b>tlb_comb</b>      | Identifies the type of Transaction Lookaside Buffer (TLB) attributes. If the TLB is present, bit 31 is 1. Otherwise, if bit 31 is less than 0, the TLB does not exist and all other TLB characteristics are 0. Bit 30 is 1 if the TLB is combined. If the TLB is separate for the instruction and data cache, bit 30 is 0. |
| <b>itlb_size</b>     | Specifies the number of entries in the instruction TLB. For combined TLBs, this is the size of the combined TLB.                                                                                                                                                                                                           |
| <b>dtlb_size</b>     | Specifies the number of entries in the data TLB. For combined TLBs, this is the size of the combined TLB.                                                                                                                                                                                                                  |
| <b>itlb_asc</b>      | Contains the associativity of the instruction TLB. This attribute's value is equal to the <b>itlb_size</b> attribute if the system is fully associative.                                                                                                                                                                   |
| <b>dtlb_asc</b>      | Contains the associativity of the instruction TLB. This attribute's value is equal to the value of the <b>dtlb_size</b> attribute if the system is fully associative.                                                                                                                                                      |
| <b>resv_size</b>     | Contains the POWER processor-based reservation granule size. This field is a 0 on POWER family machines.                                                                                                                                                                                                                   |
| <b>priv_ick_cnt</b>  | Contains the number of times lock services attempt to lock a spin lock before blocking AP process/thread in supervisor mode. This a 0 on UP machine. This parameter is used by system-locking services.                                                                                                                    |
| <b>prob_lck_cnt</b>  | Contains the number of times lock services attempt to lock a spin lock before blocking a process or thread in problem state. This a 0 on a UP machine. This parameter is used by system-locking services.                                                                                                                  |
| <b>virt_alias</b>    | Indicates virtual memory aliasing. If 1, the hardware is available for virtual memory aliasing and this ability is used by the system. Virtual memory aliasing is the mapping of one real address to more than one virtual address.                                                                                        |
| <b>cach_cong</b>     | Contains the number page index bits that can result in a cache synonym. For machines without cache synonyms, this field is 0.                                                                                                                                                                                              |

## tar.h File

### Purpose

Contains definitions for flags used in the **tar** archive header.

### Description

The **/usr/include/tar.h** file contains extended definitions used in the **typeflag** and **mode** fields of the **tar** archive header block. The file also provides values for the required POSIX entries.

#### tar Archive Header Block

Every file archived using the **tar** command is represented by a header block describing the file, followed by zero or more blocks that give the contents of the file. The end-of-archive indicator consists of two blocks filled with binary zeros. Each block is a fixed size of 512 bytes.

Blocks are grouped for physical I/O operations and groups can be written using a single **write** subroutine operation. On magnetic tape, the result of this write operation is a single tape record. The last record is always a full 512 bytes. Blocks after the end-of-archive zeros contain undefined data.

The header block structure is shown in the following table. All lengths and offsets are in decimal.

*Table 35. Header Block Structure*

| Field Name | Structure                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------|
| name       | <b>Offset:</b> 0<br><b>Length in Bytes:</b><br>100<br><b>Contents:</b><br>File name without a / (slash) |
| mode       | <b>Offset:</b> 100<br><b>Length in Bytes:</b><br>8<br><b>Contents:</b><br>File mode                     |
| uid        | <b>Offset:</b> 108<br><b>Length in Bytes:</b><br>MAXIMPL_LOGIN_NAME_MAX<br><b>Contents:</b><br>User ID  |
| gid        | <b>Offset:</b> 116<br><b>Length in Bytes:</b><br>MAXIMPL_LOGIN_NAME_MAX<br><b>Contents:</b><br>Group ID |
| size       | <b>Offset:</b> 124<br><b>Length in Bytes:</b><br>12<br><b>Contents:</b><br>Size in bytes                |
| mtime      | <b>Offset:</b> 136<br><b>Length in Bytes:</b><br>12<br><b>Contents:</b><br>Latest modification time     |
| cksum      | <b>Offset:</b> 148<br><b>Length in Bytes:</b><br>8<br><b>Contents:</b><br>File and header checksum      |
| typeflag   | <b>Offset:</b> 156<br><b>Length in Bytes:</b><br>1<br><b>Contents:</b><br>File type                     |

*Table 35. Header Block Structure (continued)*

| Field Name | Structure                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------|
| linkname   | <b>Offset:</b> 157<br><b>Length in Bytes:</b><br>100<br><b>Contents:</b><br>Linked path name or file name      |
| magic      | <b>Offset:</b> 257<br><b>Length in Bytes:</b><br>6<br><b>Contents:</b><br>Format representation for tar        |
| version    | <b>Offset:</b> 263<br><b>Length in Bytes:</b><br>3<br><b>Contents:</b><br>Version representation for tar       |
| uname      | <b>Offset:</b> 265<br><b>Length in Bytes:</b><br>32<br><b>Contents:</b><br>User name                           |
| gname      | <b>Offset:</b> 297<br><b>Length in Bytes:</b><br>32<br><b>Contents:</b><br>Group name                          |
| devmajor   | <b>Offset:</b> 329<br><b>Length in Bytes:</b><br>8<br><b>Contents:</b><br>Major device representation          |
| devminor   | <b>Offset:</b> 337<br><b>Length in Bytes:</b><br>8<br><b>Contents:</b><br>Minor device representation          |
| prefix     | <b>Offset:</b> 345<br><b>Length in Bytes:</b><br>155<br><b>Contents:</b><br>Path name without trailing slashes |

Names are preserved only if the characters are chosen from the POSIX portable file-name character set or if the same extended character set is used between systems. During a read operation, a file can be created only if the original file can be accessed using the **open**, **stat**, **chdir**, **fcntl**, or **opendir** subroutine.

## Header Block Fields

Each field within the header block and each character on the archive medium are contiguous. There is no padding between fields. More information about the specific fields and their values follows:

- name** The file's path name is created using this field, or by using this field in connection with the prefix field. If the prefix field is included, the name of the file is prefix/name. This field is null-terminated unless every character is non-null.
- mode** Provides 9 bits for file permissions and 3 bits for SUID, SGID, and SVTX modes. All values for this field are in octal. During a read operation, the designated mode bits are ignored if the user does not have equal (or higher) permissions or if the modes are not supported. Numeric fields are terminated with a space and a null byte. The **tar.h** file contains the following possible values for this field:

| Flag           | Octal | Description                 |
|----------------|-------|-----------------------------|
| <b>TSGID</b>   | 02000 | Set group ID on execution.  |
| <b>TSVTX</b>   | 01000 | Reserved.                   |
| <b>TUREAD</b>  | 00400 | Read by owner.              |
| <b>TUWRITE</b> | 00200 | Write by owner.             |
| <b>TUEXEC</b>  | 00100 | Execute or search by owner. |
| <b>TGREAD</b>  | 00040 | Read by group.              |
| <b>TGWRITE</b> | 00020 | Write by group.             |
| <b>TGEXEC</b>  | 00010 | Execute or search by group. |
| <b>TOREAD</b>  | 00004 | Read by others.             |
| <b>TOWRITE</b> | 00002 | Write by others.            |
| <b>TOEXEC</b>  | 00001 | Execute or search by other. |

- uid** Extracted from the corresponding archive fields unless a user with appropriate privileges restores the file. In that case, the field value is extracted from the password and group files instead. Numeric fields are terminated with a space and a null byte.
- gid** Extracted from the corresponding archive fields unless a user with appropriate privileges restores the file. In that case, the field value is extracted from the password and group files instead. Numeric fields are terminated with a space and a null byte.
- size** Value is 0 when the typeflag field is set to **LNKTYPE**. This field is terminated with a space only.
- mtime** Value is obtained from the modification-time field of the **stat** subroutine. This field is terminated with a space only.
- checksum** On calculation, the sum of all bytes in the header structure are treated as spaces. Each unsigned byte is added to an unsigned integer (initialized to 0) with at least 17-bits precision. Numeric fields are terminated with a space and a null byte.

### typeflag

The **tar.h** file contains the following possible values for this field:

| Flag     | Value | Description                                                               |
|----------|-------|---------------------------------------------------------------------------|
| REGTYPE  | '0'   | Regular file.                                                             |
| AREGTYPE | '\0'  | Regular file.                                                             |
| LNKTYPE  | '1'   | Link.                                                                     |
| SYMTYPE  | '2'   | Reserved.                                                                 |
| CHRTYPE  | '3'   | Character special.                                                        |
| BLKTYPE  | '4'   | Block special.                                                            |
| DIRTYPE  | '5'   | Directory. In this case, the size field has no meaning.                   |
| FIFOTYPE | '6'   | FIFO special. Archiving a FIFO file archives its existence, not contents. |
| CONTTYPE | '7'   | Reserved.                                                                 |

If other values are used, the file is extracted as a regular file and a warning issued to the standard error output. Numeric fields are terminated with a space and a null byte.

The **LNKTYPE** flag represents a link to another file, of any type, previously archived. Such linked-to files are identified by each file having the same device and file serial number. The linked-to name is specified in the **linkname** field, including a trailing null byte.

#### **linkname**

Does not use the prefix field to produce a path name. If the path name or **linkname** value is too long, an error message is returned and any action on that file or directory is canceled. This field is null-terminated unless every character is non-null.

**magic** Contains the **TMAGIC** value, reflecting the extended **tar** archive format. In this case, the **uname** and **gname** fields will contain the ASCII representation for the file owner and the file group. If a file is restored by a user with the appropriate privileges, the **uid** and **gid** fields are extracted from the password and group files (instead of the corresponding archive fields). This field is null-terminated.

#### **version**

Represents the version of the **tar** command used to archive the file. This field is terminated with a space only.

**uname** Contains the ASCII representation of the file owner. This field is null-terminated.

**gname** Contains the ASCII representation of the file group. This field is null-terminated.

#### **devmajor**

Contains the device major number. Terminated with a space and a null byte.

#### **devminor**

Contains the device minor number. Terminated with a space and a null byte.

**prefix** If this field is non-null, the file's path name is created using the **prefix/name** values together. Null-terminated unless every character is non-null.

#### **Related information:**

**tar** command

## **termio.h File**

### **Purpose**

Defines the structure of the **termio** file, which provides the terminal interface for Version 2 compatibility.

## Description

The `/usr/include/sys/termio.h` file contains the **termio** structure, which defines special characters as well as the basic input, output, control, and line discipline modes. The **termio.h** file is provided for compatibility with Version 2 applications.

Version 2 applications that include the **termio.h** file can use the Version 2 terminal interface provided by the POSIX line discipline. The following Version 2 terminal interface operations are not supported by the POSIX line discipline:

- Terminal Paging (**TCGLEN** ioctl and **TCSLEN** ioctl)
- Terminal Logging (**TCLOG** ioctl)
- Enhanced Edit Line Discipline (**LDSETDT** ioctl and **LDGETDT** ioctl)

The **termio** structure in the **termio.h** file contains the following fields:

- `c_iflag`
- `c_oflag`
- `c_cflag`
- `c_lflag`
- `c_cc`

### Field Descriptions

#### `c_iflag`

Describes the basic terminal input control. The initial input-control value is all bits clear. The possible input modes are:

##### **IGNBRK**

Ignores the break condition. In the context of asynchronous serial data transmission, a *break condition* is defined as a sequence of zero-valued bits that continues for more than the time required to send 1 byte. The entire sequence of zero-valued bits is interpreted as a single break condition, even if it continues for an amount of time equivalent to more than one byte. If the **IGNBRK** flag is set, a break condition detected on input is ignored, which means that the break condition is not put on the input queue and therefore not read by any process.

##### **BRKINT**

Interrupts the signal on the break condition. If the **IGNBRK** flag is not set and the **BRKINT** flag is set, the break condition flushes the input and output queues. If the terminal is the controlling terminal of a foreground process group, the break condition generates a single **SIGINT** signal to that foreground process group. If neither the **IGNBRK** nor the **BRKINT** flag is set, a break condition is read as a single `\0`. If the **PARMRK** flag is set, a break condition is read as `\377, \0, \0`.

##### **IGNPAR**

Ignores characters with parity errors. If this flag is set, a byte with a framing or parity error (other than break) is ignored.

##### **PARMRK**

Marks parity errors. If the **PARMRK** flag is set and the **IGNPAR** flag is not set, a byte with a framing or parity error (other than break) is given to the application as the three-character sequence `\377, \0, x`, where `\377, \0` is a two-character flag preceding each sequence and `x` is the data of the character received in error. To avoid ambiguity in this case, if the **ISTRIP** flag is not set, a valid character of `\377` is given to the application as `\377, \377`. If neither the **IGNPAR** nor the **PARMRK** flag is set, a framing or parity error (other than break) is given to the application as a single character, `\0`.

**INPCK**

Enables input parity checking. If this flag is set, input parity checking is enabled. If not set, input parity checking is disabled. This allows for output parity generation without input parity errors.

**ISTRIP**

Strips characters. If this flag is set, valid input characters are first stripped to 7 bits; otherwise, all 8 bits are processed.

**INLCR**

Maps a new-line character (NL) to a carriage return (CR) on input. If this flag is set, a received NL character is translated into a CR character.

**IGNCR**

Ignores a CR character. If this flag is set, a received CR character is ignored and not read.

**ICRNL**

Maps a CR character to an NL character on input. If the **ICRNL** flag is set and the **IGNCR** flag is not set, a received CR character is translated into an NL character.

**IUCLC**

Maps uppercase to lowercase on input. If this flag is set, a received uppercase, alphabetic character is translated into the corresponding lowercase character.

**IXON** Enables start and stop output control. If this flag is set, a received STOP character suspends output and a received START character restarts output. When the **IXON** flag is set, START and STOP characters are not read, but merely perform flow-control functions. When the **IXON** flag is not set, the START and STOP characters are read.

**IXANY**

Enables any character to restart output. If this flag is set, any input character restarts output that was suspended.

**IXOFF** Enables start-and-stop input control. If this flag is set, the system transmits a STOP character when the input queue is nearly full and a START character when enough input has been read that the queue is nearly empty again.

**c\_oflag**

Specifies how the system treats output. The initial output-control value is "all bits clear". The possible output modes are:

**OPOST**

Post processes output. If this flag is set, output characters are post-processed as indicated by the remaining flags; otherwise, characters are transmitted without change.

**OLCUC**

Maps lowercase to uppercase on output. If this flag is set, a lowercase alphabetic character is transmitted as the corresponding uppercase character. This function is often used in conjunction with the **IUCLC** input mode.

**ONLCR**

Maps NL to CR-NL on output. If this flag is set, the NL character is transmitted as the CR-NL character pair.

**OCRNL**

Maps CR to NL on output. If this flag is set, the CR character is transmitted as the NL character.

**ONOCR**

Indicates no CR output at column 0 (first position). If this flag is set, no CR character is transmitted when at column 0 (first position).

## **ONLRET**

NL performs the CR function. If this flag is set, the NL character is assumed to do the carriage-return function. The column pointer is set to 0, and the delay specified for carriage return is used. If neither the **ONLCR**, **OCRNL**, **ONOCR**, nor **ONLRET** flag is set, the NL character is assumed to do the line-feed function only. The column pointer remains unchanged. The column pointer is also set to 0 if the CR character is actually transmitted.

The delay bits specify how long a transmission stops to allow for mechanical or other movement when certain characters are sent to the terminal. The actual delays depend on line speed and system load.

**OFILL** Uses fill characters for delay. If this flag is set, fill characters are transmitted for a delay instead of a timed delay. This is useful for high baud rate terminals that need only a minimal delay.

## **OFDEL**

If this flag is set, the fill character is DEL. If this flag is not set, the fill character is NULL.

## **NLDLY**

Selects the new-line character delays. This is the mask to use before comparing to NL0 and NL1:

**NL0** Specifies no delay.

**NL1** Specifies one delay of approximately 0.10 seconds. If the **ONLRET** flag is set, the carriage-return delays are used instead of the new-line delays. If the **OFILL** flag is set, two fill characters are transmitted.

## **CRDLY**

Selects the carriage-return delays. This is the mask to use before comparing to CR0, CR1, CR2, and CR3:

**CR0** Specifies no delay.

**CR1** Specifies that the delay is dependent on the current column position. If the **OFILL** flag is set, two fill characters are transmitted.

**CR2** Specifies a delay of approximately 0.10 seconds. If the **OFILL** flag is set, this delay transmits four fill characters.

**CR3** Specifies one delay of approximately 0.15 seconds.

## **TABDLY**

Selects the horizontal-tab delays. This is the mask to use before comparing to TAB0, TAB1, TAB2, and TAB3. If the **OFILL** flag is set, any of these delays (except TAB3) transmit two fill characters:

**TAB0** Specifies no delay.

**TAB1** Specifies that the delay is dependent on the current column position. If the **OFILL** flag is set, two fill characters are transmitted.

**TAB2** Specifies a delay of approximately 0.10 seconds.

**TAB3** Specifies that tabs are to be expanded into spaces.

## **BSDLY**

Selects the backspace delays. This is the mask to use before comparing to BS0 and BS1:

**BS0** Specifies no delay.

**BS1** Specifies a delay of approximately 0.05 seconds. If the **OFILL** flag is set, this delay transmits one fill character.

**VTDLY**

Selects the vertical-tab delays. This is the mask to use before comparing to VT0 and VT1:

**VT0** Specifies no delay.

**VT1** Specifies one delay of approximately 2 seconds.

**FFDLY**

Selects the form-feed delays. This is a mask to use before comparing to FF0 and FF1:

**FF0** Specifies no delay.

**FF1** Specifies a delay of approximately 2 seconds.

**c\_cflag**

Describes the hardware control of the terminal. In addition to the basic control modes, this field uses the following control characters:

**CBAUD**

Specifies baud rate. These bits specify the baud rate for a connection. For any particular hardware, impossible speed changes are ignored.

**B0** Specifies a zero baud rate which is used to hang up the connection. If B0 is specified, the `data terminal ready' signal is not asserted. As a result, the line is usually disconnected. This delay transmits two fill characters. Normally, this disconnects the line.

**B50** Specifies 50 baud.

**B75** Specifies 75 baud.

**B110** Specifies 110 baud.

**B134** Specifies 134.5 baud.

**B150** Specifies 150 baud.

**B200** Specifies 200 baud.

**B300** Specifies 300 baud.

**B600** Specifies 600 baud.

**B1200** Specifies 1200 baud.

**B1800** Specifies 1800 baud.

**B2400** Specifies 2400 baud.

**B4800** Specifies 4800 baud.

**B9600** Specifies 9600 baud.

**B19200**  
Specifies 19,200 baud.

**B38400**  
Specifies 38,400 baud.

**EXTA** Specifies External A.

**EXTB** Specifies External B.

**CSIZE** Specifies the character size. These bits specify the character size, in bits, for both transmit and receive operations. The character size does not include the parity bit, if one is used:

**CS5** 5 bits

**CS6** 6 bits

**CS7** 7 bits

**CS8** 8 bits

#### **CSTOPB**

Specifies the number of stop bits. If this flag is set, 2 stop bits are sent; otherwise, only 1 stop bit is sent.

#### **CREAD**

Enables the receiver. If this flag is set, the receiver is enabled. Otherwise, characters are not received.

#### **PARENB**

Enables parity. If this flag is set, parity generation and detection is enabled and a parity bit is added to each character.

#### **PARODD**

Specifies odd parity. If parity is enabled, the **PARODD** flag specifies odd parity if set. If parity is enabled and the **PARODD** flag is not set, even parity is used.

#### **HUPCL**

Hangs up on last close. If this flag is set, the line is disconnected when the last process closes the line or when the process terminates (when the `data terminal ready' signal drops).

#### **CLOCAL**

Specifies a local line. If this flag is set, the line is assumed to have a local, direct connection with no modem control. If not set, modem control (dial-up connection) is assumed.

### **c\_flag**

Controls various terminal functions. The initial value after an open is "all bits clear." This field uses the following mask name symbols:

**ISIG** Enables signals. If this flag is set, each input character is checked against the INTR and QUIT special control characters. If an input character matches one of these control characters, the function associated with that character is performed. If the **ISIG** function is not set, checking is not done.

#### **ICANON**

Enables canonical input. If this flag is set, it turns on canonical processing, which enables the erase and kill edit functions as well as the assembly of input characters into lines delimited by NL, EOF, and EOL characters. If the **ICANON** flag is not set, read requests are satisfied directly from the input queue. In this case, a read request is not satisfied until one of the following conditions is met:

- The minimum number of characters specified by the **MIN** value are received.
- The time-out value specified by the **TIME** value has expired since the last character was received.

As a result bursts of input can be read, while still allowing single-character input. The **MIN** and **TIME** values are stored in the positions for the EOF and EOL characters, respectively. The character values of **MIN** and **TIME** are converted to their ascii equivalents to get the numeric value. The time value represents tenths of seconds.

#### **XCASE**

Enables canonical uppercase and lowercase presentation. If this flag is set along with the **ICANON** flag, an uppercase letter (or the uppercase letter translated to lowercase by the **IUCLC** input mode) is accepted on input by preceding it with a \ (backslash) character. The output is then also preceded by a backslash character. In this mode, the output generates and the input accepts the following escape sequences:

| For:      | Use: |
|-----------|------|
| ` (grave) | \`   |
|           | \!   |
| ~         | \^   |
| {         | \(   |
| }         | \)   |
| \         | \ \  |

For example, A is input as \a, \n as \\n, and \N as \\\n.

#### NOFLSH

Disables queue flushing. If this flag is set, the normal flushing of the input and output queues associated with the INTR and QUIT characters is not done.

**ECHO** Enables echo. If this flag is set, characters are echoed as they are received.

When the **ICANON** flag is set, the following echo functions are possible:

#### ECHOE

Echoes the erase character as Backspace-Space-Backspace. If the **ECHO** and **ECHOE** flags are both set, the ERASE character is echoed as one or more ASCII Backspace-Space-Backspace sequences, which clears the last characters from the screen.

#### ECHOK

Echoes the NL character after kill. If the **ECHOK** flag is set, the NL character is echoed after the kill character is received. This emphasizes that the line is deleted.

#### ECHONL

Echoes the NL character. If the **ECHONL** flag is set, the NL character is echoed even if the **ECHO** flag is not set. This is useful for terminals that are set to "local echo" (also referred to as "half-duplex").

**c\_cc** Specifies an array that defines the special control characters. The relative positions and initial values for each function are:

#### VINTR

Indexes the INTR special character (Ctrl-c), which is recognized on input if the **ISIG** flag is set. The INTR character generates a **SIGINT** signal, which is sent to all processes in the foreground process group for which the terminal is the controlling terminal. If the **ISIG** flag is set, the INTR character is discarded when processed.

#### VQUIT

Indexes the QUIT special character (Ctrl-\), which is recognized on input if the **ISIG** flag is set. The QUIT character generates a **SIGQUIT** signal, which is sent to all processes in the foreground process group for which the terminal is the controlling terminal, and writes a **core** image file into the current working directory. If the **ISIG** flag is set, the QUIT character is discarded when processed.

#### VERASE

Indexes the ERASE special character (Backspace), which is recognized on input if the **ICANON** flag is set. The ERASE character does not erase beyond the beginning of the line as delimited by a NL, EOL, EOF, or EOL2 character. If the **ICANON** flag is set, the ERASE character is discarded when processed.

#### VKILL

Indexes the KILL special character (Ctrl-u), which is recognized on input if the **ICANON** flag is set. The KILL character deletes the entire line, as delimited by an NL, EOL, EOF, or EOL2 character. If the **ICANON** flag is set, the KILL character is discarded when processed.

**VEOF** Indexes the EOF special character (Ctrl-d), which is recognized on input if the **ICANON** flag is set. When EOF is received, all the characters waiting to be read are immediately

passed to the process, without waiting for a new line, and the EOF is discarded. If the EOF is received at the beginning of a line (no characters are waiting), a character count of zero is returned from the read, indicating an end-of-file. If the **ICANON** flag is set, the EOF character is discarded when processed.

**VEOL** Indexes the EOL special character (Ctrl-@ or ASCII NULL), which is recognized on input if the **ICANON** flag is set. EOL is an additional line delimiter, like NL, and is not normally used.

#### **VEOL2**

Indexes the EOL2 special character (Ctrl-@ or ASCII NULL), which is recognized on input if the **ICANON** flag is set. EOL2 is another additional line delimiter, like NL, and is not normally used.

**VMIN** Indexes the **MIN** value, which is not a special character. The use of the **MIN** value is described in the discussion of non-canonical mode input processing in "POSIX (termios.h File) Line Discipline" in *General Programming Concepts: Writing and Debugging Programs*.

#### **VTIME**

Indexes the TIME value, which is not a special character. The use of the TIME value is described in the discussion of non-canonical mode input processing in "POSIX (termios.h File) Line Discipline" in *General Programming Concepts: Writing and Debugging Programs*.

The character values for the following control characters can be changed:

- INTR
- ERASE
- EOF
- EOL2
- QUIT
- KILL
- EOL

The ERASE, KILL, and EOF characters can also be escaped (preceded with a backslash) so that no special processing is done.

The primary ioctl subroutines have the form:

```
ioctl (FileDescriptor, Command, Structure)
struct termio *Structure;
```

The operations using this form are:

#### **TCGETA**

Gets the parameters associated with the terminal and stores them in the **termio** structure referenced by the *Structure* parameter.

#### **TCSETA**

Sets the parameters associated with the terminal from the structure referenced by the *Structure* parameter. The change is immediate.

#### **TCSETAF**

Waits for the output to drain, and then flushes the input queue and sets the new parameters.

#### **TCSETAW**

Waits for the output to drain before setting the new parameters. This form should be used when changing parameters that will affect output.

Other ioctl subroutines have the form:

```
ioctl (FileDescriptor, Command, Value)
int Value;
```

The operations using this form are:

**Note:** If the user writes an application that performs a **TCSBRK** operation followed by a **TCFLSH** operation prior to closing a port, the last data left in the concentrator box on the 64-port adapter is lost. However, no problem occurs if an SIO, 8-port, or 16-port adapter is used.

#### **TCSBRK**

Waits for the output to drain. If the *Value* parameter has a value of 0, it sends a break of 0.25 seconds. A nonzero value causes a break condition of that many milliseconds.

#### **TCSBREAK**

Waits for the output to drain. If the *Value* parameter has a value of 0, it sends a break of .25 seconds. A nonzero value causes a break condition of that many milliseconds.

#### **TCXONC**

Starts and stops control. If the *Value* parameter has a value of 0, it suspends output. If the *Value* parameter has a value of 1, it restarts suspended output. If the *Value* parameter has a value of 2, it blocks input. If the *Value* parameter has a value of 3, it unblocks input.

#### **TCFLSH**

If the *Value* parameter has a value of 0, it flushes the input queue. If the *Value* parameter has a value of 1, it flushes the output queue. If the *Value* parameter has a value of 2, it flushes both the input and output queues.

Another form for ioctl subroutines is:

```
ioctl (FileDescriptor, Command, Structure)
struct csmap* Structure;
```

#### **TCSCSMAP**

Sets the code set map from the structure referenced by the structure parameter and rejects any invalid map (any map with 0 length/width or a length greater than **MB\_LEN\_MAX**). The **/usr/include/sys/tty.h** file contains the structure used for **TCSCSMAP** and **TCGCSMAP** operations.

#### **TCGCSMAP**

Returns a copy of the current code set map in the structure referenced by the structure parameter. The **/usr/include/sys/tty.h** file contains the structure used for **TCSCSMAP** and **TCGCSMAP** operations.

The following ioctl operations are used for trusted communications path operations:

#### **TCSAK**

Points to an integer that enables the Secure Attention Key (SAK) sequence (Ctrl-X, Ctrl-R) to provide a clean terminal to which only trusted processes can read or write. When SAK is enabled and the user types this sequence, all processes that are currently running are ended. The **TCSAKON** operation turns the SAK sequence on; the **TCSAKOFF** operation turns the SAK sequence off.

#### **TCQSAK**

Queries the state (**TCSAKON** or **TCSAKOFF**) of the SAK sequence.

#### **TCTRUST**

Sets a bit by which another process can query, (with the **TCQTRUST** operation), the state of the terminal, (**TCTRUSTED** or **TCUNTRUSTED**).

#### **TCQTRUST**

Queries the state of the terminal (**TCTRUSTED** or **TCUNTRUSTED**).

## termios.h File

### Purpose

Defines the structure of the **termios** file, which provides the terminal interface for POSIX compatibility.

### Description

The **/usr/include/termios.h** file contains information used by subroutines that apply to terminal files. The definitions, values, and structures in this file are required for compatibility with the POSIX standard. The **termios.h** file also supports ioctl modem-control operations.

The general terminal interface information is contained in the **termio.h** file. The **termio** structure in the **termio.h** file defines the basic input, output, control, and line discipline modes. If a calling program is identified as requiring POSIX compatibility, the **termios** structure and additional POSIX control-packet information in the **termios.h** file is implemented. Window and terminal size operations use the **winsize** structure, which is defined in the **ioctl.h** file. The **termios** structure in the **termios.h** file contains the following fields:

- **c\_iflag**
- **c\_oflag**
- **c\_cflag**
- **c\_lflag**
- **c\_cc**

The **termios.h** file also defines the values for the following parameters of the **tcsetattr** subroutine:

- *OptionalActions*
- *QueueSelector*
- *Action*

The **termios.h** file also supports ioctl modem-control operations.

### Field Descriptions

#### **c\_iflag**

Describes the basic terminal input control. The initial input-control value is all bits clear. The possible input modes are:

##### **IGNBRK**

Ignores the break condition. In the context of asynchronous serial data transmission, a *break condition* is defined as a sequence of zero-valued bits that continues for more than the time required to send one byte. The entire sequence of zero-valued bits is interpreted as a single break condition, even if it continues for an amount of time equivalent to more than one byte. If the **IGNBRK** flag is set, a break condition detected on input is ignored, which means that it is not put on the input queue and therefore not read by any process.

##### **BRKINT**

Signal interrupt on the break condition. If the **IGNBRK** flag is not set and the **BRKINT** flag is set, the break condition flushes the input and output queues. If the terminal is the controlling terminal of a foreground process group, the break condition generates a

**SIGINT** signal to that foreground process group. If neither the **IGNBRK** nor the **BRKINT** flag is set, a break condition is read as a single \0, or if the **PARMRK** flag is set, as \377, \0, \0.

#### **IGNPAR**

Ignores characters with parity errors. If this flag is set, a byte with a framing or parity error (other than break) is ignored.

#### **PARMRK**

Marks parity errors. If the **PARMRK** flag is set, and the **IGNPAR** flag is not set, a byte with a framing or parity error (other than break) is given to the application as the three-character sequence \377, \0, x, where \377, \0 is a two-character flag preceding each sequence and x is the data of the character received in error. To avoid ambiguity in this case, if the **ISTRIP** flag is not set, a valid character of \377 is given to the application as \377, \377. If neither the **IGNPAR** nor the **PARMRK** flag is set, a framing or parity error (other than break) is given to the application as a single character \0.

#### **INPCK**

Enables input parity checking. If this flag is set, input parity checking is enabled. If not set, input parity checking is disabled. This allows for output parity generation without input parity errors.

#### **ISTRIP**

Strips characters. If this flag is set, valid input characters are first stripped to 7 bits. Otherwise, all 8 bits are processed.

#### **INLCR**

Maps a new-line character (NL) to a carriage return (CR) on input. If this flag is set, a received NL character is translated into a CR character.

#### **IGNCR**

Ignores CR character. If this flag is set, a received CR character is ignored and not read.

#### **ICRNL**

Maps a CR character to the NL character on input. If the **ICRNL** flag is set and the **IGNCR** flag is not set, a received CR character is translated into a NL character.

#### **IUCLC**

Maps uppercase to lowercase on input. If this flag is set, a received uppercase, alphabetic character is translated into the corresponding lowercase character.

**IXON** Enables start and stop output control. If this flag is set, a received STOP character suspends output and a received START character restarts output. When the **IXON** flag is set, START and STOP characters are not read, but merely perform flow-control functions. When the **IXON** flag is not set, the START and STOP characters are read.

#### **IXANY**

Enables any character to restart output. If this flag is set, any input character restarts output that was suspended.

**IXOFF** Enables start-and-stop input control. If this flag is set, the system transmits a STOP character when the input queue is nearly full and a START character when enough input has been read that the queue is nearly empty again.

#### **IMAXBEL**

Echoes the ASCII BEL character if the input stream overflows. Further input is not stored, but input already present in the input stream is not lost. If this flag is not set, no BEL character is echoed; the input in the input queue is discarded if the input stream overflows. This function also requires the **IEXTEN** bit to be set.

**c\_oflag**

Specifies how the system treats output. The initial output-control value is "all bits clear." The possible output modes are:

**OPOST**

Post-processes output. If this flag is set, output characters are post-processed as indicated by the remaining flags. Otherwise, characters are transmitted without change.

**OLCUC**

Maps lowercase to uppercase on output. If this flag is set, a lowercase alphabetic character is transmitted as the corresponding uppercase character. This flag is often used in conjunction with the **IUCLC** input mode.

**ONLCR**

Maps NL to CR-NL on output. If this flag is set, the NL character is transmitted as the CR-NL character pair.

**OCRNL**

Maps CR to NL on output. If this flag is set, the CR character is transmitted as the NL character.

**ONOCR**

Indicates no CR output at column 0. If this flag is set, no CR character is transmitted when at column 0 (first position).

**ONLRET**

NL performs CR function. If this flag is set, the NL character is assumed to do the carriage-return function. The column pointer is set to 0, and the delay specified for carriage return is used. If neither the **ONLCR**, **OCRNL**, **ONOCR**, nor **ONLRET** flag is set, the NL character is assumed to do the line-feed function only. The column pointer remains unchanged. The column pointer is set to 0 if the CR character is actually transmitted.

The delay bits specify how long a transmission stops to allow for mechanical or other movement when certain characters are sent to the terminal. The actual delays depend on line speed and system load.

**OFILL** Uses fill characters for delay. If this flag is set, fill characters are transmitted for a delay instead of a timed delay. This is useful for high baud rate terminals that need only a minimal delay.

**OFDEL**

If this flag is set, the fill character is DEL. If this flag is not set, the fill character is NULL.

**NLDLY**

Selects the new-line character delays. This is the mask to use before comparing to NL0 and NL1:

**NL0** Specifies no delay.

**NL1** Specifies a delay of approximately 0.10 seconds. If the **ONLRET** flag is set, the carriage-return delays are used instead of the new-line delays. If the **OFILL** flag is set, two fill characters are transmitted.

**CRDLY**

Selects the carriage-return delays. This is the mask to use before comparing to CR0, CR1, CR2, and CR3:

**CR0** Specifies no delay.

**CR1** Specifies that the delay is dependent on the current column position. If the **OFILL** flag is set, this delay transmits two fill characters.

**CR2** Specifies a delay of approximately 0.10 seconds. If the **OFILL** flag is set, this delay transmits four fill characters.

**CR3** Specifies a delay of approximately 0.15 seconds.

#### **TABDLY**

Selects the horizontal-tab delays. This is the mask to use before comparing to TAB0, TAB1, TAB2, and TAB3. If the **OFILL** flag is set, any of these delays (except TAB3) transmit two fill characters.

**TAB0** Specifies no delay.

**TAB1** Specifies that the delay is dependent on the current column position. If the **OFILL** flag is set, two fill characters are transmitted.

**TAB2** Specifies a delay of approximately 0.10 seconds.

**TAB3** Specifies that tabs are to be expanded into spaces.

#### **BSDLY**

Selects the backspace delays. This is the mask to use before comparing to BS0 and BS1:

**BS0** Specifies no delay.

**BS1** Specifies a delay of approximately 0.05 seconds. If the **OFILL** flag is set, this delay transmits one fill character.

#### **VTDLY**

Selects the vertical-tab delays. This is the mask to use before comparing to VT0 and VT1:

**VT0** Specifies no delay.

**VT1** Specifies a delay of approximately 2 seconds.

#### **FFDLY**

Selects the form-feed delays. This is the mask to use before comparing to FF0 and FF1:

**FF0** Specifies no delay.

**FF1** Specifies a delay of approximately 2 seconds.

#### **c\_cflag**

Describes the hardware control of the terminal. In addition to the basic control modes, this field uses the following control characters:

#### **CBAUD**

Specifies baud rate. These bits specify the baud rate for a connection. For any particular hardware, impossible speed changes are ignored.

**B50** 50 baud.

**B75** 75 baud.

**B110** 110 baud.

**B134** 134.5 baud.

**B150** 150 baud.

**B200** 200 baud.

**B300** 300 baud.

**B600** 600 baud.

**B1200** 1200 baud.

**B1800** 1800 baud.

**B2400** 2400 baud.

**B4800** 4800 baud.

**B9600** 9600 baud.

**B19200**

19200 baud.

**B38400**

38400 baud.

**EXTA** External A.

**EXTB** External B.

**CSIZE** Specifies the character size. These bits specify the character size, in bits, for both transmit and receive operations. The character size does not include the parity bit, if one is used:

**CS5** 5 bits

**CS6** 6 bits

**CS7** 7 bits

**CS8** 8 bits.

**CSTOPB**

Specifies number of stop bits. If this flag is set, 2 stop bits are sent; otherwise, only 1 stop bit is sent.

**CREAD**

Enables receiver. If this flag is set, the receiver is enabled. Otherwise, characters are not received.

**PARENB**

Enables parity. If this flag is set, parity generation and detection is enabled and a parity bit is added to each character.

**PARODD**

Specifies odd parity. If parity is enabled, the **PARODD** flag specifies odd parity if set. If parity is enabled and the **PARODD** flag is not set, even parity is used.

**HUPCL**

Hangs up on last close. If this flag is set, the line is disconnected when the last process closes the line or when the process terminates (when the `data terminal ready' signal drops).

**CLOCAL**

Specifies a local line. If this flag is set, the line is assumed to have a local, direct connection with no modem control. If not set, modem control (dial-up) is assumed.

**CIBAUD**

Specifies the input baud rate if different from the output rate.

**PAREXT**

Specifies extended parity for mark and space parity.

**c\_flag**

Controls various terminal functions. The initial value after an open is "all bits clear." In addition to the basic modes, this field uses the following mask name symbols:

**ISIG** Enables signals. If this flag is set, each input character is checked against the INTR, QUIT, SUSP, and DSUSP special control characters. If an input character matches one of these control characters, the function associated with that character is performed. If the **ISIG** flag is not set, checking is not done.

**ICANON**

Enables canonical input. If this flag is set, it turns on canonical processing, which enables the erase and kill edit functions as well as the assembly of input characters into lines

delimited by NL, EOF, and EOL characters. If the **ICANON** flag is not set, read requests are satisfied directly from the input queue. In this case, a read request is not satisfied until one of the following conditions is met:

- The minimum number of characters specified by **MIN** are received.
- The time-out value specified by **TIME** has expired since the last character was received. This allows bursts of input to be read, while still allowing single-character input.

The **MIN** and **TIME** values are stored in the positions for the EOF and EOL characters, respectively. The character values of **MIN** and **TIME** are converted to their ascii equivalents to get the numeric value. The time value represents tenths of seconds.

#### **XCASE**

Enables canonical uppercase and lowercase presentation. If this flag is set along with the **ICANON** flag, an uppercase letter (or the uppercase letter translated to lowercase by the **IUCLC** input mode) is accepted on input by preceding it with a \ (backslash) character. The output is then also preceded by a backslash character. In this mode, the output generates and the input accepts the following escape sequences:

**For**      **Use**

|           |     |
|-----------|-----|
| ` (grave) | \ ` |
|           | \ ! |
| ~         | \ ^ |
| {         | \ ( |
| }         | \ ) |
| \         | \ \ |

For example, A is input as \a, \n as \\n, and \N as \\\n.

#### **NOFLSH**

Disables queue flushing. If this flag is set, the normal flushing of the input and output queues associated with the INTR, QUIT, and SUSP characters is not done.

#### **FLUSHO**

Flushes the output. When this bit is set by typing the FLUSH character, data written to the terminal is discarded. A terminal can cancel the effect of typing the FLUSH character by clearing this bit.

#### **PENDIN**

Reprints pending input. If this flag is set, any input that is pending after a switch from raw to canonical mode is re-input the next time a read operation becomes pending or the next time input arrives. The **PENDIN** flag is an internal-state bit.

#### **IEXTEN**

Enables extended (implementation-defined) functions to be recognized from the input data. If this flag is not set, implementation-defined functions are not recognized, and the corresponding input characters are processed as described for the **ICANON**, **ISIG**, **IXON**, and **IXOFF** flags. Recognition of the following special control characters requires the **IEXTEN** flag to be set:

- **VEOL2**
- **VDSUSP**
- **VREPRINT**
- **VDISCRD**
- **VWERSE**

- **VLNEXT**

The functions associated with the following bits also require the **IEXTEN** flag to be set:

- **IMAXBEL**
- **ECHOKE**
- **ECHOPRT**
- **ECHOCTL**

#### **TOSTOP**

Sends a **SIGTTOU** signal when a process in a background process group tries to write to its controlling terminal. The **SIGTTOU** signal stops the members of the process group.

**ECHO** Enables echo. If this flag is set, characters are echoed as they are received.

When the **ICANON** is set, the following echo functions are also possible:

#### **ECHOE**

Echoes the erase character as Backspace-Space-Backspace. If the **ECHO** and **ECHOE** flags are both set and the **ECHOPRT** flag is not set, the ERASE and WERASE characters are echoed as one or more ASCII Backspace-Space-Backspace sequences, which clears the last characters from the screen.

#### **ECHOPRT**

If the **ECHO** and **ECHOPRT** flags are both set, the first ERASE and WERASE character in a sequence are echoed as a \ (backslash), followed by the characters being erased. Subsequent ERASE and WERASE characters echo the characters being erased, in reverse order. The next non-erase character causes a / (slash) to be typed before the nonerase character is echoed. This function also requires the **IEXTEN** bit to be set.

#### **ECHOKE**

Backspace-Space-Backspace entire line on line kill. If this flag is set, the kill character is echoed by erasing the entire line from the screen (using the mechanism selected by the **ECHOE** and **ECHOPRT** flags). This function also requires the **IEXTEN** flag to be set.

#### **ECHOK**

Echoes the NL character after kill. If the **ECHOK** flag is set and the **ECHOKE** flag is not set, the NL character is echoed after the kill character is received. This emphasizes that the line is deleted.

#### **ECHONL**

Echoes the NL character. If the **ECHONL** flag is set, the NL character is echoed even if the **ECHO** flag is not set. This is useful for terminals that are set to "local echo" (also referred to as "half-duplex").

#### **ECHOCTL**

Echoes control characters (with codes between 0 and 37 octal) as ^X, where X is the character that results from adding 100 octal to the code of the control character. (For example, the character with octal code 1 is echoed as ^A). The ASCII DEL character (code 177 octal) is echoed as ^?. The ASCII TAB, NL, and START characters are not echoed. Unless escaped (preceded by a backslash), the EOF character is not echoed. As a result, because EOT is the default EOF character, terminals that respond to EOT are prevented from hanging up. This function also requires the **IEXTEN** flag to be set.

**c\_cc** Specifies an array that defines the special control characters. The relative positions and initial values for each function are:

#### **VINTR**

Indexes the INTR special character (Ctrl-c), which is recognized on input if the **ISIG** flag is set. The INTR character generates a **SIGINT** signal, which is sent to all processes in the foreground process group for which the terminal is the controlling terminal. If the **ISIG** flag is set, the INTR character is discarded when processed.

**VQUIT**

Indexes the QUIT special character (Ctrl-\), which is recognized on input if the **ISIG** flag is set. The QUIT character generates a **SIGQUIT** signal, which is sent to all processes in the foreground process group for which the terminal is the controlling terminal, and writes a **core** image file into the current working directory. If the **ISIG** flag is set, the QUIT character is discarded when processed.

**VERASE**

Indexes the ERASE special character (Backspace), which is recognized on input if the **ICANON** flag is set. The ERASE character does not erase beyond the beginning of the line as delimited by a NL, EOL, EOF, or EOL2 character. If the **ICANON** flag is set, the ERASE character is discarded when processed.

**VKILL**

Indexes the KILL special character (Ctrl-u), which is recognized on input if the **ICANON** flag is set. The KILL character deletes the entire line, as delimited by a NL, EOL, EOF, or EOL2 character. If the **ICANON** flag is set, the KILL character is discarded when processed.

**VEOF**

Indexes the EOF special character (Ctrl-d), which is recognized on input if the **ICANON** flag is set. When EOF is received, all the characters waiting to be read are immediately passed to the process, without waiting for a new line, and the EOF is discarded. If the EOF is received at the beginning of a line (no characters are waiting), a character count of zero is returned from the read, indicating an end-of-file. If the **ICANON** flag is set, the EOF character is discarded when processed.

**VEOL**

Indexes the EOL special character (Ctrl-@ or ASCII NULL), which is recognized on input if the **ICANON** flag is set. EOL is an additional line delimiter, like NL, and is not normally used.

**VEOL2**

Indexes the EOL2 special character (Ctrl-@ or ASCII NULL), which is recognized on input if the **ICANON** and **IEXTEN** flags are set. EOL2 is an additional line delimiter, like NL, and is not normally used.

**VSTART**

Indexes the START special character (Ctrl-q), which is recognized on input if the **IXON** flag is set, and generated on output if the **IXOFF** flag is set. The START character can be used to resume output that has been suspended by a STOP character. If the **IXON** flag is set, the START character is discarded when processed. While output is not suspended, START characters are ignored and not read. **VSTRT** is an alias for **VSTART**.

**VSTOP**

Indexes the STOP special character (Ctrl-s), which is recognized on input if the **IXON** flag is set, and generated on output if the **IXOFF** flag is set. The STOP character can be used to prevent output from disappearing before it can be read. If the **IXON** flag is set, the STOP character is discarded when processed. While output is suspended, STOP characters are ignored and not read.

**VSUSP**

Indexes the SUSP special character (Ctrl-z), which is recognized on input if the **ISIG** flag is set. The SUSP character generates a **SIGTSTP** signal, which is sent to all processes in the foreground process group for which the terminal is the controlling terminal. If the **ISIG** flag is set, the SUSP character is discarded when processed.

**VDSUSP**

Indexes the DSUSP special character (Ctrl-y), which is recognized on input if the **ISIG** and **IEXTEN** flags are set. The DSUSP character generates a **SIGTSTP** signal as the SUSP character does, but the signal is sent when a process in the foreground process group

attempts to read the DSUSP character, rather than when DSUSP is typed. If the **ISIG** and **IEXTEN** flags are set, the DSUSP character is discarded when processed.

#### VREPRINT

Indexes the REPRINT special character (Ctrl-r), which is recognized on input if the **ICANON** and **IEXTEN** flags are set. The REPRINT character reprints all characters, preceded by a new line, that have not been read. If the **ICANON** and **IEXTEN** flags are set, the REPRINT character is discarded when processed.

#### VDISCRD

Indexes the DISCARD special character (Ctrl-o), which is recognized on input if the **ICANON** and **IEXTEN** flags are set. The DISCARD character causes subsequent output to be discarded until another DISCARD character is typed, more input arrives, or the condition is cleared by a program. If the **ICANON** and **IEXTEN** flags are set, the DISCARD character is discarded when processed.

#### VWERSE

Indexes the WERASE special character (Ctrl-w), which is recognized on input if the **ICANON** and **IEXTEN** flags are set. The WERASE character causes the preceding word to be erased. The WERASE character does not erase beyond the beginning of the line as delimited by a NL, EOL, EOF, or EOL2 character. If the **ICANON** and **IEXTEN** flags are set, the WERASE character is discarded when processed.

#### VLNEXT

Indexes the LNEXT (literal next) special character (Ctrl-v), which is recognized on input if the **ICANON** and **IEXTEN** flags are set. The LNEXT character causes the special meaning of the next character to be ignored so that characters can be input without being interpreted by the system. If the **ICANON**, **ECHO**, and **IEXTEN** flags are set, the LNEXT character is replaced by a ^-Backspace sequence when processed.

**VMIN** Indexes the **MIN** value, which is not a special character. The use of the **MIN** value is described in the discussion of noncanonical mode input processing in "ldterm Line Discipline" in *General Programming Concepts: Writing and Debugging Programs*.

#### VTIME

Indexes the **TIME** value, which is not a special character. The use of the **TIME** value is described in the discussion of noncanonical mode input processing in "ldterm Line Discipline" in *General Programming Concepts: Writing and Debugging Programs*.

The character values for the following control characters can be changed:

| Item  | Description | Value   | Value   |
|-------|-------------|---------|---------|
| INTR  | EOF         | STOP    | DISCARD |
| QUIT  | EOL         | SUSP    | WERASE  |
| ERASE | EOL2        | DSUSP   | LNEXT   |
| KILL  | START       | REPRINT | REPRINT |

The ERASE, KILL, and EOF characters can also be escaped (preceded by a backslash) so that no special processing is done.

#### Parameter Value Definitions

The following values for the *OptionalActions* parameter of the **tcsetattr** subroutine are also defined in the **termios.h** file:

| Item      | Description                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCSANOW   | Immediately sets the parameters associated with the terminal from the referenced <b>termios</b> structure.                                                                                                    |
| TCSADRAIN | Waits until all output written to the object file has been transmitted before setting the terminal parameters from the <b>termios</b> structure.                                                              |
| TCSAFLUSH | Waits until all output written to the object file has been transmitted and until all input received but not read has been discarded before setting the terminal parameters from the <b>termios</b> structure. |

The following values for the *QueueSelector* parameter of the **tcflush** subroutine are also defined in this header file:

| Item      | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| TCIFLUSH  | Flushes data that is received but not read.                                                     |
| TCOFLUSH  | Flushes data that is written but not transmitted.                                               |
| TCIOFLUSH | Flushes data that is received but not read as well as data that is written but not transmitted. |

The following values for the *Action* parameter of the **tcflow** subroutine are also defined in the **termios.h** file:

| Item   | Description                                                                               |
|--------|-------------------------------------------------------------------------------------------|
| TCOFF  | Suspends the output of data by the object file named in the <b>tcflow</b> subroutine.     |
| TCOON  | Restarts data output that was suspended by the TCOFF action.                              |
| TCIOFF | Transmits a stop character to stop data transmission by the terminal device.              |
| TCION  | Transmits a start character to start or restart data transmission by the terminal device. |

## Modem Control Operations

The following ioctl operations, used for modem control, are an extension to the POSIX line discipline interface. To use these operations in a program, the program must contain an **#include** statement for the **ioctl.h** file.

| Item     | Description                                                                                                                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TIOCMBIS | The argument to this command is a pointer to an integer that turns on the control lines specified by the integer mask value. No other control lines are affected.                                                                                                                |
| TIOCMBIC | The argument to this command is a pointer to an integer that turns off the control lines specified by the integer mask value. No other control lines are affected.                                                                                                               |
| TIOCMGET | Gets all modem bits. The argument to this command is a pointer to an integer where the current state of the modem status lines is stored. Which modem status and modem control lines are supported depends on the capabilities of the hardware and the hardware's device driver. |

| Item              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TIOCMSET</b>   | Sets all modem bits. The argument to this command is a pointer to an integer containing a new set of modem bits. The modem control bits use these bits to turn the modem control lines on or off, depending on whether the bit for that line is set or clear. Any modem status bits are ignored. The actual modem control lines which are supported depend on the capabilities of the hardware and the hardware's device driver.<br><br>The integer specifies one of the following modem control or status lines on which the modem control <b>ioctl</b> command operates: |
|                   | <b>TIOCM_LE</b><br>Line enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                   | <b>TIOCM_DTR</b><br>Data terminal ready                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## **termiox.h** File

### **Purpose**

Defines the structure of the **termiox** file, which provides the extended terminal interface.

### **Description**

The **termiox.h** file contains an extended terminal interface to support asynchronous hardware flow control. It defines the **termiox** structure and ioctl operations using this structure. The **termiox** structure in the **termiox.h** file contains the following fields:

- **x\_hflag**
- **x\_cflag**
- **x\_rflag**
- **x\_sflag**

The **termiox.h** file also supports ioctl hardware flow control operations.

| <b>Field</b>   | <b>Descriptions</b>                                                                                                                                                                                                                                                 |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>x_hflag</b> | Describes the hardware flow control mode. The possible modes are:                                                                                                                                                                                                   |
| <b>CDXON</b>   | Enables CD hardware flow control on output. When set, output will occur only if the 'receive line signal detector' (CD) line is raised by the connected device. If the CD line is dropped by the connected device, output is suspended until the CD line is raised. |
| <b>CTSXON</b>  | Enables CTS hardware flow control on output. When set, output will occur only if the 'clear to send' (CTS) line is raised by the connected device. If the CTS line is dropped by the connected device, output is suspended until the CTS line is raised.            |
| <b>DTRXOFF</b> | Enables DTR hardware flow control on input. When set, the 'data terminal ready' (DTR) line is raised. If the port needs to have its input stopped, it will drop the DTR line. It is assumed that the connected device will stop its output until DTR is raised.     |
| <b>RTSXOFF</b> | Enables RTS hardware flow control on input. When set, the 'request to send' (RTS) line is raised. If the port needs to have its input stopped, it will drop the RTS line. It is assumed that the connected device will stop its output until RTS is raised.         |

It is not possible to use simultaneously the following flow control modes:

- RTS and DTR
- CTS and CD.

Different hardware flow control modes may be selected by setting the appropriate flags. For example:

- Bi-directional RTS/CTS flow control by setting **RTSXOFF** and **CTSXON**
- Bi-directional DTR/CTS flow control by setting **DTRXOFF** and **CTSXON**
- Modem control or uni-directional CTS flow control by setting **CTSXON**.

**x\_cflag**

Reserved for future use.

**x\_rflag**

Reserved for future use.

| Field    | Descriptions                                                                                                                                                                                                                                                                                                                |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| x_sflag  | Describes the open discipline. This field must be set before the first open; it is usually done at configuration time. The possible disciplines are:                                                                                                                                                                        |
| DTR_OPEN | DTR open discipline. On open, the discipline raises the `data terminal ready' (DTR) and `request to send' (RTS) lines, and waits for the `data carrier detect' (DCD) line to be raised. If the port is opened with the O_NDELAY or O_NONBLOCK flags, the wait is not done. The DTR and RTS lines are dropped at close time. |
| WT_OPEN  | World trade open discipline. On open, the discipline behaves like the DTR open discipline if not in CDSTL mode. In CDSTL mode, the discipline does not raise the DTR line until the `ring indicate' (RI) line is raised. The DTR line is dropped when the DSR line drops for more than 20 milliseconds.                     |

## Hardware Flow Control Operations

The following ioctl operations are used for hardware flow control. To use these operations in a program, the program must contain an #include statement for the **ioctl.h** file. The argument to these operations is a pointer to a **termiox** structure.

| Item    | Description                                                                                                                                                                                                                                                                      |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| TCGETX  | Gets the terminal parameters. The current terminal parameters are stored in the structure.                                                                                                                                                                                       |
| TCSETX  | Sets the terminal parameters immediately. The current terminal parameters are set according to the structure. The change is immediate.                                                                                                                                           |
| TCSETXW | Sets the terminal parameters after end of output. The current terminal parameters are set according to the structure. The change occurs after all characters queued for output have been transmitted. This operation should be used when changing parameters will affect output. |
| TCSETXF | Sets the terminal parameters after end of output and flushes input. The current terminal parameters are set according to the structure. All characters queued for output are first transmitted, then all characters queued for input are discarded, and then the change occurs.  |

tty Subsystem Overview

## threads.h File

### Purpose

The **threads.h** header file includes the **time.h** header file and defines macros. It also declares types, enumeration constants, and functions that support multiple threads of execution.

### Description

The header **threads.h** header file must not be provided by implementations that define the macro **\_STDC\_NO\_THREADS\_**. Also, such implementations must not support any facilities that are specified by the header **threads.h** file.

The **threads.h** header file declares the following macros:

#### thread\_local

Expands to **\_Thread\_local**.

#### ONCE\_FLAG\_INIT

Expands to a value that can be used to initialize an object of the type **once\_flag**.

## TSS\_DTOR\_ITERATIONS

Expands to an integer constant expression that represents the maximum number of times a destructor is called when a thread terminates.

The **threads.h** header file declares following types:

**cnd\_t** A complete object type that holds an identifier for a condition variable.

**thrd\_t** A complete object type that holds an identifier for a thread.

**tss\_t** A complete object type that holds an identifier for a thread-specific storage pointer.

**mtx\_t** A complete object type that holds an identifier for a mutex.

### **tss\_dtor\_t**

A function pointer type **void (\*)(void\*)**, used for a destructor for a thread-specific storage pointer.

### **thrd\_start\_t**

A function pointer type **int (\*)(void\*)** that is passed to **thrd\_create** to create a new thread.

### **once\_flag**

A complete object type that holds a flag for use by **call\_once**.

The **threads.h** header file declares the following enumeration constants:

### **mtx\_plain**

The **mtx\_plain** type is passed to **mtx\_init** to create a mutex object that does not support timeout and test and returns.

### **mtx\_recursive**

The **mtx\_recursive** type is passed to **mtx\_init** to create a mutex object that supports recursive locking.

### **mtx\_timed**

The **mtx\_timed** type is passed to **mtx\_init** to create a mutex object that supports timeout.

### **thrd\_timeout**

The **cnd\_t** type is returned by a timed wait function to indicate that the time specified in the call was reached without acquiring the requested resource.

### **thrd\_success**

The **thrd\_success** type is returned by the function to indicate that the requested operation succeeded.

### **thrd\_busy**

The **thrd\_busy** type is returned by the function to indicate that the requested operation failed because a resource requested by a test and return functions is already in use.

### **thrd\_error**

The **thrd\_error** type is returned by a function to indicate that the requested operation failed.

### **thrd\_nomem**

The **thrd\_nomem** type is returned by a function to indicate that the requested operation failed because it was unable to allocate memory.

The **threads.h** header file declares the following functions:

```
void call_once(once_flag *flag, void (*func)(void));
int cnd_broadcast(cnd_t *cond);
void cnd_destroy(cnd_t *cond);
int cnd_init(cnd_t *cond);
int cnd_signal(cnd_t *cond);
int cnd_timedwait(cnd_t *restrict cond,
 mtx_t *restrict mtx,
 const struct timespec *restrict ts);
int cnd_wait(cnd_t *cond, mtx_t *mtx);
```

```

void mtx_destroy(mtx_t *mtx);
int mtx_init(mtx_t *mtx, int type);
int mtx_lock(mtx_t *mtx);
int mtx_timedlock(mtx_t *restrict mtx,
const struct timespec *restrict ts);
int mtx_trylock(mtx_t *mtx);
int mtx_unlock(mtx_t *mtx);
int thrd_create(thrd_t *thr, thrd_start_t func,
void *arg);
thrd_t thrd_current(void);
int thrd_detach(thrd_t thr);
int thrd_equal(thrd_t thr0, thrd_t thr1);
_Noreturn void thrd_exit(int res);
int thrd_join(thrd_t thr, int *res);
int thrd_sleep(const struct timespec *duration,
struct timespec *remaining);
void thrd_yield(void);
int tss_create(tss_t *key, tss_dtor_t dtor);
void tss_delete(tss_t key);
void *tss_get(tss_t key);
int tss_set(tss_t key, void *val);

```

## trace.h File

### Purpose

Defines implementation trace that IEEE POSIX 1003 identifies.

### Description

The *<trace.h>* header defines the **posix\_trace\_event\_info** structure that includes the following members:

|                  |                         |
|------------------|-------------------------|
| trace_event_id_t | posix_event_id          |
| pid_t            | posix_pid               |
| void             | *posix_prog_address     |
| int              | posix_truncation_status |
| struct timespec  | posix_timestamp         |
| pthread_t        | posix_thread_id         |

The *<trace.h>* header defines the **posix\_trace\_status\_info** structure that includes the following members:

|     |                             |
|-----|-----------------------------|
| int | posix_stream_status         |
| int | posix_stream_full_status    |
| int | posix_stream_overrun_status |
| int | posix_stream_flush_status   |
| int | posix_stream_flush_error    |
| int | posix_log_overrun_status    |
| int | posix_log_full_status       |

The *<trace.h>* header defines the following symbols:

**Table 36. Symbols for the trace.h header**

| Symbol                      | Usage                                                                                                  | Description                                                                                                                                                                                                                      |
|-----------------------------|--------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POSIX_TRACE_ADD_EVENTSET    | how argument of the <code>posix_trace_set_filter()</code> function                                     | The resulting set of trace event types to be filtered is the union of the current set and the trace event type set that the argument set points to.                                                                              |
| POSIX_TRACE_ALL_EVENTS      | what argument of the <code>posix_trace_eventset_fill()</code> function                                 | All trace event types defined, both system and user, are included in the set.                                                                                                                                                    |
| POSIX_TRACE_APPEND          | <code>logpolicy</code> argument of the <code>posix_trace_attr_setlogfullpolicy()</code> function       | The associated trace stream is flushed to the trace log without log size limitation.                                                                                                                                             |
| POSIX_TRACE_CLOSE_FOR_CHILD | <code>inheritancepolicy</code> argument of the <code>posix_trace_eventset_fill()</code> function       | After a <code>fork()</code> operation or a <code>spawn()</code> operation, the child is not traced, and tracing of the parent continues.                                                                                         |
| POSIX_TRACE_FILTER          |                                                                                                        | This event is recorded in the stream when a trace-event-type filter is changed.                                                                                                                                                  |
| POSIX_TRACE_FLUSH           | <code>streampolicy</code> argument of the <code>posix_trace_attr_setstreamfullpolicy()</code> function | This policy is identical to the <code>POSIX_TRACE_UNTIL_FULL</code> trace-stream full policy, except that the trace stream is flushed regularly as if the <code>posix_trace_flush()</code> operation has been explicitly called. |
| POSIX_TRACE_FLUSH_START     |                                                                                                        | This event is recorded in the stream marking the beginning of a flush operation.                                                                                                                                                 |
| POSIX_TRACE_FLUSH_STOP      |                                                                                                        | This event is recorded in the stream marking the end of a flush operation.                                                                                                                                                       |
| POSIX_TRACE_FLUSHING        | <code>posix_stream_flush_status</code> member of the <code>posix_trace_status_info</code> structure    | The trace stream is being flushed to the trace log.                                                                                                                                                                              |
| POSIX_TRACE_FULL            | <code>posix_stream_full_status</code> member of the <code>posix_trace_status_info</code> structure     | The space in the trace stream for trace events is exhausted.                                                                                                                                                                     |
| POSIX_TRACE_FULL            | <code>posix_log_full_status</code> member of the <code>posix_trace_status_info</code> structure        | The space in the trace log is exhausted.                                                                                                                                                                                         |
| POSIX_TRACE_LOOP            | <code>streampolicy</code> argument of the <code>posix_trace_attr_setstreamfullpolicy()</code> function | The trace stream loops until the <code>posix_trace_stop()</code> subroutine explicitly stops it.                                                                                                                                 |
| POSIX_TRACE_LOOP            | <code>logpolicy</code> argument of the <code>posix_trace_attr_setlogfullpolicy()</code> function       | The trace log loops until the associated trace stream is stopped.                                                                                                                                                                |
| POSIX_TRACE_NO_OVERRUN      | <code>posix_stream_overrun_status</code> member of the <code>posix_trace_status_info</code> structure  | No trace events are lost in the stream.                                                                                                                                                                                          |
| POSIX_TRACE_NO_OVERRUN      | <code>posix_log_overrun_status</code> member of the <code>posix_trace_status_info</code> structure     | No trace events are lost in the trace log.                                                                                                                                                                                       |
| POSIX_TRACE_NOT_FLUSHING    | <code>posix_stream_flush_status</code> member of the <code>posix_trace_status_info</code> structure    | No flush operation is in progress.                                                                                                                                                                                               |
| POSIX_TRACE_NOT_FULL        | <code>posix_stream_full_status</code> member of the <code>posix_trace_status_info</code> structure     | There is space available in the trace stream.                                                                                                                                                                                    |
| POSIX_TRACE_NOT_FULL        | <code>posix_log_full_status</code> member of the <code>posix_trace_status_info</code> structure        | There is space available in the trace log.                                                                                                                                                                                       |
| POSIX_TRACE_INHERITED       | <code>inheritancepolicy</code> argument of the <code>posix_trace_attr_setinherited()</code> function   | After a <code>fork()</code> operation or a <code>spawn()</code> operation, if the parent is traced, its child is traced concurrently using the same trace stream.                                                                |
| POSIX_TRACE_NOT_TRUNCATED   | <code>posix_truncation_status</code> member of the <code>posix_trace_event_info</code> structure       | All of the traced data is available.                                                                                                                                                                                             |
| POSIX_TRACE_OVERFLOW        |                                                                                                        | This event is recorded in the stream marking the beginning of a trace overflow condition.                                                                                                                                        |
| POSIX_TRACE_OVERRUN         | <code>posix_stream_overrun_status</code> member of the <code>posix_trace_status_info</code> structure  | At least one trace event is lost and not recorded in the trace stream.                                                                                                                                                           |
| POSIX_TRACE_OVERRUN         | <code>posix_log_overrun_status</code> member of the <code>posix_trace_status_info</code> structure     | At least one trace event is lost in the trace log.                                                                                                                                                                               |
| POSIX_TRACE_RESUME          |                                                                                                        | This event is recorded in the stream marking the end of a trace overflow condition.                                                                                                                                              |
| POSIX_TRACE_RUNNING         | <code>posix_stream_status</code> member of the <code>posix_trace_status_info</code> structure          | Tracing is in progress.                                                                                                                                                                                                          |

*Table 36. Symbols for the trace.h header (continued)*

| Symbol                         | Usage                                                                                                  | Description                                                                                                                                                                                                                                                                  |
|--------------------------------|--------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| POSIX_TRACE_SET_EVENTSET       | how argument of the <code>posix_trace_set_filter()</code> function                                     | The resulting set of trace event types to be filtered is the trace event type set that the argument set points to.                                                                                                                                                           |
| POSIX_TRACE_START              |                                                                                                        | This event is recorded in the stream on a trace start operation.                                                                                                                                                                                                             |
| POSIX_TRACE_STOP               |                                                                                                        | This event is recorded in the stream on a trace stop operation.                                                                                                                                                                                                              |
| POSIX_TRACE_SUB_EVENTSET       | how argument of the <code>posix_trace_set_filter()</code> function                                     | The resulting set of trace event types to be filtered includes all trace event types in the current set. These trace event types are not in the set pointed to by the argument set. Each element of the current set of trace event types is removed from the current filter. |
| POSIX_TRACE_SUSPENDED          | <code>posix_stream_status</code> member of the <code>posix_trace_status_info</code> structure          | The tracing operation has not started, or has stopped.                                                                                                                                                                                                                       |
| POSIX_TRACE_SYSTEM_EVENTS      | what argument of the <code>posix_trace_eventset_fill()</code> function                                 | All the system-trace-event types are included in the set.                                                                                                                                                                                                                    |
| POSIX_TRACE_TRUNCATED_READ     | <code>posix_truncation_status</code> member of the <code>posix_trace_event_info</code> structure       | Data is truncated at the time the trace event is read from a trace stream or a trace log because the reader's buffer is too small.                                                                                                                                           |
| POSIX_TRACE_TRUNCATED_RECORD   | <code>posix_truncation_status</code> member of the <code>posix_trace_event_info</code> structure       | Data is truncated at the time the trace event is generated.                                                                                                                                                                                                                  |
| POSIX_TRACE_UNNAMED_USER_EVENT |                                                                                                        | If the per-process user name of the trace event is reached, the <code>POSIX_TRACE_UNNAMED_USEREVENT</code> user trace event is returned on <code>posix_trace_eventid_open()</code> or <code>posix_trace_trid_eventid_open()</code> .                                         |
| POSIX_TRACE_UNTIL_FULL         | <code>streampolicy</code> argument of the <code>posix_trace_attr_getstreamfullpolicy()</code> function | The trace stream runs until the trace stream resources are exhausted; then the trace stream stops.                                                                                                                                                                           |
| POSIX_TRACE_UNTIL_FULL         | <code>logpolicy</code> argument of the <code>posix_trace_attr_getlogfullpolicy()</code> function       | The trace stream is flushed to the trace log until the trace log is full.                                                                                                                                                                                                    |
| POSIX_TRACE_WOPID_EVENTS       | what argument of the <code>posix_trace_eventset_fill()</code> function                                 | All the process-independent, system-trace-event types are included in the set.                                                                                                                                                                                               |

The following types are defined as described in the header `types.h` file:

`trace_attr_t`  
`trace_id_t`  
`trace_event_id_t`  
`trace_event_set_t`

```
int posix_trace_attr_destroy(trace_attr_t *);
int posix_trace_attr_getclockres(const trace_attr_t *,
 struct timespec *);
int posix_trace_attr_getcreatetime(const trace_attr_t *,
 struct timespec *);
int posix_trace_attr_getgenversion(const trace_attr_t *, char *);
int posix_trace_attr_getinherited(const trace_attr_t *restrict,
 int *restrict);
int posix_trace_attr_getlogfullpolicy(const trace_attr_t *restrict,
 int *restrict);
int posix_trace_attr_getlogsize(const trace_attr_t *restrict,
 size_t *restrict);
int posix_trace_attr_getmaxdatasize(const trace_attr_t *restrict,
 size_t *restrict);
int posix_trace_attr_getmaxsystemeventsizesize(const trace_attr_t *restrict,
 size_t *restrict);
int posix_trace_attr_getmaxusereventsizesize(const trace_attr_t *restrict,
```

```

 size_t, size_t *restrict);
int posix_trace_attr_getname(const trace_attr_t *, char *);
int posix_trace_attr_getstreamfullpolicy(const trace_attr_t *restrict,
 int *restrict);
int posix_trace_attr_getstreamsize(const trace_attr_t *restrict,
 size_t *restrict);
int posix_trace_attr_init(trace_attr_t *);
int posix_trace_attr_setinherited(trace_attr_t *, int);
int posix_trace_attr_setlogfullpolicy(trace_attr_t *, int);
int posix_trace_attr_setlogsize(trace_attr_t *, size_t);

## types.h File

### Purpose

Defines primitive system data types.

### Description

The `/usr/include/sys/types.h` file defines data types used in system source code. Since some system data types are accessible to user code, they can be used to enhance portability across different machines and operating systems. For example, the `pid_t` type allows for more processes than the unsigned short (`ushort_t`) type, and the `dev_t` type can be 16 bits rather than 32 bits.

### Standard Type Definitions

The `types.h` file includes the following standard type definitions, which are defined with a `typedef` statement:

| Item                  | Description                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>daddr_t</code>  | Used for disk addresses, except in i-nodes on disk. The <code>/usr/include/sys/filsys.h</code> file format describes the format of disk addresses used in i-nodes.                                                                                                 |
| <code>caddr_t</code>  | Core (memory) address.                                                                                                                                                                                                                                             |
| <code>clock_t</code>  | Used for system times as specified in <code>CLK_TCKs</code> .                                                                                                                                                                                                      |
| <code>ino_t</code>    | File system i-node number.                                                                                                                                                                                                                                         |
| <code>cnt_t</code>    | File system reference count type.                                                                                                                                                                                                                                  |
| <code>dev_t</code>    | Major and minor parts of a device code specify the kind of device and unit number of the device and depend on how the system is customized.                                                                                                                        |
| <code>chan_t</code>   | Channel number (the minor's minor).                                                                                                                                                                                                                                |
| <code>off_t</code>    | File offset, measured in bytes from the beginning of a file or device. <code>off_t</code> is normally defined as a signed, 32-bit integer. In the programming environment which enables large files, <code>off_t</code> is defined to be a signed, 64-bit integer. |
| <code>offset_t</code> | 64-bit file offset, measured in bytes from the beginning of a file or device.                                                                                                                                                                                      |
| <code>off64_t</code>  | 64-bit file offset, measured in bytes from the beginning of a file or device.                                                                                                                                                                                      |
| <code>soff_t</code>   | 32-bit file offset, measured in bytes from the beginning of a file or device.                                                                                                                                                                                      |
| <code>paddr_t</code>  | Real address.                                                                                                                                                                                                                                                      |
| <code>key_t</code>    | IPC key.                                                                                                                                                                                                                                                           |
| <code>time_t</code>   | Timer ID. Times are encoded in seconds, since 00:00:00 UCT, January 1, 1970.                                                                                                                                                                                       |
| <code>nlink_t</code>  | Number of file links.                                                                                                                                                                                                                                              |
| <code>mode_t</code>   | File mode.                                                                                                                                                                                                                                                         |
| <code>uid_t</code>    | User ID.                                                                                                                                                                                                                                                           |
| <code>gid_t</code>    | Group ID.                                                                                                                                                                                                                                                          |
| <code>mid_t</code>    | Module ID.                                                                                                                                                                                                                                                         |
| <code>pid_t</code>    | Process ID.                                                                                                                                                                                                                                                        |
| <code>slab_t</code>   | Security label.                                                                                                                                                                                                                                                    |
| <code>mtyp_t</code>   | Interprocess communication (IPC) message type.                                                                                                                                                                                                                     |
| <code>size_t</code>   | Data type is used for sizes of objects.                                                                                                                                                                                                                            |
| <code>ssize_t</code>  | Data type is used for a count of bytes or an error indication.                                                                                                                                                                                                     |

| Item              | Description                  |
|-------------------|------------------------------|
| uchar_t           | Unsigned char.               |
| ushort_t          | Unsigned short.              |
| uint_t            | Unsigned int.                |
| ulong_t           | Unsigned long.               |
| trace_attr_t      | Trace attributes object.     |
| trace_id_t        | Trace stream identifier.     |
| trace_event_id_t  | Trace-event-type identifier. |
| trace_event_set_t | Trace-event-type set.        |

## Unsigned Integers and Addresses

The **types.h** file also includes the following type definitions for unsigned integers and addresses:

```
typedef struct _quad { long val[2]; } quad;
typedef long swblk_t;
typedef unsigned long size_t;
```

The following type definitions are for BSD compatibility only:

```
typedef unsigned char u_char;
typedef unsigned short u_short;
typedef unsigned int u_int;
typedef unsigned long u_long;
```

## uchar.h File

### Purpose

Declares types and functions for manipulating the Unicode characters.

### Description

The **uchar.h** file declares following types:

#### char16\_t

An unsigned integer type used for 16-bit characters. It is similar to the **uint\_least16\_t** type.

#### char32\_t

An unsigned integer types used for 32-bit characters. It is similar to **uint\_least32\_t** type.

The **uchar.h** file also lists the prototype declarations for the following Unicode utility functions: **mbrtoc16()**, **mbrtoc32()**, **c16rtomb()**, and **c32rtomb()**.

## unistd.h File

### Purpose

Defines implementation characteristics identified by POSIX standard.

### Description

The **/usr/include/unistd.h** file includes files that contain definitions that are required for compatibility with the POSIX standard:

| Item     | Description                                                  |
|----------|--------------------------------------------------------------|
| access.h | Defines symbolic constants for the <b>access</b> subroutine. |

The **unistd.h** file also defines symbolic constants for the **pathconf**, **fpathconf**, and **sysconf** subroutines. The **unistd.h** file also defines the following symbols, which are used by POSIX applications to determine implementation characteristics:

| Item                           | Description                                                                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>_POSIX_JOB_CONTROL</b>      | POSIX-compatible job control is supported.                                                                                                                                                                                                        |
| <b>_POSIX_SAVED_IDS</b>        | An <b>exec</b> subroutine saves the effective user and group IDs.                                                                                                                                                                                 |
| <b>_POSIX_VERSION</b>          | The version of the POSIX standard with which this version of the operating system complies. The value of this symbol is 198808L.                                                                                                                  |
| <b>_POSIX_CHOWN_RESTRICTED</b> | The use of the <b>chown</b> function is restricted to a process with the appropriate privileges. The group ID of a file can be changed only to the effective group ID or a supplementary group ID of the process. The value of this symbol is -1. |
| <b>_POSIX_VDISABLE</b>         | The terminal special characters, which are defined in the <b>termios.h</b> file, can be disabled if this character value is defined by the <b>tcsetattr</b> subroutine. The value of this symbol is -1.                                           |
| <b>_POSIX_NO_TRUNC</b>         | Path name components that are longer than <b>NAME_MAX</b> will generate an error.                                                                                                                                                                 |

The **unistd.h** file also defines the following symbol, which is used by X/OPEN applications:

| Item                  | Description                                                                                  |
|-----------------------|----------------------------------------------------------------------------------------------|
| <b>_XOPEN_VERSION</b> | The version of the X/OPEN standard with which this version of the operating system complies. |

access subroutine

## utmp.h File

### Purpose

Defines the structures of certain user and accounting information files.

### Description

The structure of the records in the **utmp**, **wtmp**, and **failedlogin** files is defined in the **/usr/include/utmp.h** file. The **utmp** structure in this header file contains the following fields:

| <b>Item</b>                 | <b>Description</b>                                                                                                                                                                                                           |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ut_user</code>        | User login name.                                                                                                                                                                                                             |
| <code>ut_line</code>        | Device name (console or lnx). The maximum length of a string in this field is 11 characters plus a null character. When accounting for something other than a process, the following special strings or formats are allowed: |
| <b>RUNLVL_MSG</b>           | Run level: specifically, the run level of the process.                                                                                                                                                                       |
| <b>BOOT_MSG</b>             | System boot: specifically, the time of the initial program load (IPL).                                                                                                                                                       |
| <b>OTIME_MSG</b>            | Old time: specifically, the time of login.                                                                                                                                                                                   |
| <b>NTIME_MSG</b>            | New time: specifically, the time idle.                                                                                                                                                                                       |
| <code>ut_pid</code>         | Process ID.                                                                                                                                                                                                                  |
| <code>ut_type</code>        | Type of entry, which can be one of the following values:                                                                                                                                                                     |
| <b>EMPTY</b>                | Unused space in file.                                                                                                                                                                                                        |
| <b>RUN_LVL</b>              | The run level of the process, as defined in the <b>inittab</b> file.                                                                                                                                                         |
| <b>BOOT_TIME</b>            | The time at which the system was started.                                                                                                                                                                                    |
| <b>OLD_TIME</b>             | The time at which a user logged on to the system.                                                                                                                                                                            |
| <b>NEW_TIME</b>             | The amount of time the user is idle.                                                                                                                                                                                         |
| <b>INIT_PROCESS</b>         | A process spawned by the <b>init</b> command.                                                                                                                                                                                |
| <b>LOGIN_PROCESS</b>        | A <b>getty</b> process waiting for a login.                                                                                                                                                                                  |
| <b>USER_PROCESS</b>         | A user process.                                                                                                                                                                                                              |
| <b>DEAD_PROCESS</b>         | A zombie process.                                                                                                                                                                                                            |
| <b>ACCOUNTING</b>           | A system accounting process.                                                                                                                                                                                                 |
| <b>UTMAXTYPE ACCOUNTING</b> | The largest legal value allowed in the <code>ut_type</code> field.                                                                                                                                                           |

Embedded within the **utmp** structure is the **exit\_status** structure, which contains the following fields:

| <b>Item</b>                | <b>Description</b>                                                 |
|----------------------------|--------------------------------------------------------------------|
| <code>e_termination</code> | Termination status of a process.                                   |
| <code>e_exit</code>        | Exit status of a process, marked as the <b>DEAD_PROCESS</b> value. |
| <code>ut_time</code>       | Time at which the entry was made.                                  |

## Examples

```
#ifndef -H-UTMP
#define _H_UTMP
#define UTMP_FILE "/etc/utmp"
#define WTMP_FILE "/var/adm/wtmp"
#define ILOG_FILE "/etc/.ilog"
#define ut_name ut_user

struct utmp
{
 char ut_user[256]; /* User login name */
```

```

char ut_id[14]; /* /etc/inittab id */
char ut_line[64]; /* device name (console, lnx) */
pid_t ut_pid; /* process id */
short ut_type; /* type of entry */

#if !defined(_64BIT_)
 int _time_t_space; /* for 32vs64-bit time_t PPC */
#endif

time_t ut_time; /* time entry was made */

struct exit_status
{
 short e_termination; /* Process termination status */
 short e_exit; /* Process exit status */
};

ut_exit; /* The exit status of a process
 * marked as DEAD_PROCESS.
 */

char ut_host[256]; /* host name */
int _dbl_word_pad; /* for double word alignment */
int _reservedA[2];
int _reservedV[6];
};

/* Definitions for ut_type */

#define EMPTY 0
#define RUN_LVL 1
#define BOOT_TIME 2
#define OLD_TIME 3
#define NEW_TIME 4
#define INIT_PROCESS 5 /* Process spawned by "init" */
#define LOGIN_PROCESS 6 /* A "getty" process */

#define USER_PROCESS 7 /* waitingforlogin */
#define DEAD_PROCESS 8 /* A user process */
#define ACCOUNTING 9
#define UTMAXTYPE ACCOUNTING /* Largest legal value */
 /* of ut_type */

/* Special strings or formats used in the
/* "ut_line" field when accounting for
/* something other than a process.
/* No string for the ut_line field can be more
/* than 11 chars + a NULL in length. */

#define RUNLVL_MSG "run-level %c"
#define BOOT_MSG "system boot"
#define OTIME_MSG "old time"
#define TIME_MSG "new time"

#endif /* _H_UTMP */

```

**Note:** The **who** command extracts information from the **/etc/utmp**, **/var/adm/wtmp**, and **/etc/security/failedlogin** files.

## Files

| Item                      | Description                                                                                    |
|---------------------------|------------------------------------------------------------------------------------------------|
| /etc/utmp                 | The path to the <b>utmp</b> file, which contains a record of users logged in to the system.    |
| /var/adm/wtmp             | The path to the <b>wtmp</b> file, which contains accounting information about logged-in users. |
| /etc/security/failedlogin | The path to the <b>failedlogin</b> file, which contains a list of invalid login attempts.      |

## values.h File

### Purpose

Defines machine-dependent values.

### Description

The **/usr/include/values.h** file contains a set of constants that are conditionally defined for particular processor architectures. The model for integers is assumed to be a ones or twos complement binary representation, in which the sign is represented by the value of the high-order bit.

| Item                     | Description                                                                                      |
|--------------------------|--------------------------------------------------------------------------------------------------|
| <b>BITS(<i>type</i>)</b> | Number of bits in the specified data type                                                        |
| <b>HIBITS</b>            | Short integer with only the high-order bit set (0x8000)                                          |
| <b>HIBITL</b>            | Long integer with only the high-order bit set (0x80000000)                                       |
| <b>HIBITI</b>            | Regular integer with only the high-order bit set (same as the <b>HIBITL</b> value)               |
| <b>MAXSHORT</b>          | Maximum value of a signed short integer (0x7FFF = 32,767)                                        |
| <b>MAXLONG</b>           | Maximum value of a signed long integer (0x7FFFFFFF = 2,147,483,647)                              |
| <b>MAXINT</b>            | Maximum value of a signed regular integer (same as the <b>MAXLONG</b> value)                     |
| <b>MAXFLOAT</b>          | Maximum value of a single-precision floating-point number                                        |
| <b>MAXDOUBLE</b>         | Maximum value of a double-precision floating-point number                                        |
| <b>LN_MAXDOUBLE</b>      | Natural logarithm of the <b>MAXDOUBLE</b> value                                                  |
| <b>MINFLOAT</b>          | Minimum positive value of a single-precision floating-point number                               |
| <b>MINDOUBLE</b>         | Minimum positive value of a double-precision floating-point number                               |
| <b>FSIGNIF</b>           | Number of significant bits in the mantissa of a single-precision floating-point number           |
| <b>DSIGNIF</b>           | Number of significant bits in the mantissa of a double-precision floating-point number           |
| <b>FMAXEXP</b>           | Maximum exponent of a single-precision floating-point number                                     |
| <b>DMAXEXP</b>           | Maximum exponent of a double-precision floating-point number                                     |
| <b>FMINEXP</b>           | Minimum exponent of a single-precision floating-point number                                     |
| <b>DMINEXP</b>           | Minimum exponent of a double-precision floating-point number                                     |
| <b>FMAXPOWTWO</b>        | Largest power of two that can be exactly represented as a single-precision floating-point number |
| <b>DMAXPOWTWO</b>        | Largest power of two that can be exactly represented as a double-precision floating-point number |

## **vmount.h File**

### **Purpose**

Defines the structure of the data associated with a virtual file system.

### **Description**

The `/usr/include/sys/vmount.h` file defines the **vmount** structure. Each active virtual file system (VFS) has a **vmount** structure associated with it. The **vmount** structure contains the mount parameters (such as the mount object and the mounted-over object) for that VFS. The **vmount** data is created when the VFS is mounted. The **mntctl** subroutine returns the VFS data.

The **vmount** structure contains the following fields to describe fixed-length data:

| Item          | Description                                                                                                                                                                                           |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vmt_revision  | The revision code in effect when the program that created this VFS was compiled.                                                                                                                      |
| vmt_length    | The total length of the structure and data. This will always be a multiple of the word size (4 bytes).                                                                                                |
| vmt_fsid      | The two-word file system identifier; the interpretation of this identifier depends on the vmt_gfstype field.                                                                                          |
| vmt_vfsnumber | The unique identifier of the VFS. Virtual file systems and their identifiers are deleted at IPL (initial program load).                                                                               |
| vmt_time      | The time at which the VFS was created.                                                                                                                                                                |
| vmt_flags     | The general mount flags, for example: <b>READONLY</b> , <b>REMOVABLE</b> , <b>DEVICE</b> , <b>REMOTE</b> .                                                                                            |
| vmt_gfstype   | The type of the general file system. Possible values are:<br><br><b>MNT_JFS</b><br>Journaled file system (JFS)<br><b>MNT_NFS</b><br>SUN network file system<br><b>MNT_CDROM</b><br>CD-ROM file system |

The remaining fields in the **vmount** structure describe variable-length data. Each entry in the **vmt\_data** array specifies the offset from the start of the **vmount** structure at which a data item appears, as well as the length of the data item.

| Item                   | Description                                                                                                                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| vmt_off                | Offset of the data, aligned on a word (32-bit) boundary.                                                                                                                                               |
| vmt_size               | Actual size of the data in bytes.                                                                                                                                                                      |
| vmt_data[VMT_OBJECT]   | Name of the device, directory, or file that is mounted.                                                                                                                                                |
| vmt_data[VMT_STUB]     | Name of the device, directory, or file that is mounted over.                                                                                                                                           |
| vmt_data[VMT_HOST]     | Short (binary) name of the host that owns the mounted object.                                                                                                                                          |
| vmt_data[VMT_HOSTNAME] | Long (character) name of the host that owns the mounted object.                                                                                                                                        |
| vmt_data[VMT_INFO]     | Binary information passed to the file system implementation that supports this object; the contents of this field are specific to the generic file system (GFS) type defined by the vmt_gfstype field. |
| vmt_data[VMT_ARGS]     | Character-string representation of the arguments supplied when the VFS was created.                                                                                                                    |

## wctype.h File

### Purpose

Contains wide-character classification and mapping utilities.

### Syntax

```
#include <wctype.h>
```

### Description

The **wctype.h** header defines the following data types through typedef:

| Item             | Description                                                                           |
|------------------|---------------------------------------------------------------------------------------|
| <b>wint_t</b>    | As described in <b>wchar.h</b> .                                                      |
| <b>wctrans_t</b> | A scalar type that can hold values that represent locale-specific character mappings. |
| <b>wctype_t</b>  | As described in <b>wchar.h</b> .                                                      |

The **wctype.h** header declares the following as functions and may also define them as macros. Function prototypes must be provided for use with an ISO C compiler.

```
int iswalnum(wint_t);
int iswalpha(wint_t);
int iswcntrl(wint_t);
int iswdigit(wint_t);
int iswgraph(wint_t);
int iswlower(wint_t);
int iswprint(wint_t);
int iswpunct(wint_t);
int iswspace(wint_t);
int iswupper(wint_t);
int iswdxdigit(wint_t);
int iswctype(wint_t, wctype_t);
wint_t towctrans(wint_t, wctrans_t);
wint_t towlower(wint_t);
wint_t towupper(wint_t);
wctrans_t wctrans(const char *);
wctype_t wctype(const char *);
```

The **wctype.h** defines the following macro name:

| Item        | Description                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------------------|
| <b>WEOF</b> | Constant expression of type <b>wint_t</b> that is returned by several MSE functions to indicate end-of-file. |

For all functions described in this header that accept an argument of type **wint\_t**, the value will be representable as a **wchar\_t** or will equal the value of **WEOF**. If this argument has any other value, the behaviour is undefined.

The behaviour of these functions is affected by the **LC\_CTYPE** category of the current locale.

Inclusion of the **wctype.h** header may make visible all symbols from the headers **ctype.h**, **stdio.h**, **stdarg.h**, **stdlib.h**, **string.h**, **stddef.h** **time.h** and **wchar.h**.

## wlm.h File

### Purpose

Defines the constants, data structures and function prototypes used by the Workload Manager (WLM) Application Programming Interface (API) subroutines.

### Description

The **wlm.h** file defines the **wlm\_args**, **wlm\_assign**, **wlm\_info**, **wlm\_bio\_class\_info\_t**, and **wlm\_bio\_dev\_info\_t**, and **wlm\_proc\_info** structures. These structures are used by the WLM API functions in the **libwlm.a** library.

#### The **wlm\_args** Structure

The **wlm\_args** structure is used to pass class information to WLM when using the API functions to create, modify or delete a class. The **wlm\_args** structure contains the following fields:

##### **versflags**

Specifies the 4 high-order bits that contain a version number used by the API to maintain binary compatibility if the data structures are ever modified. The rest of the integer is used to pass flags to the subroutines when needed.

This field should be initialized with a logical **OR** operation between the version number **WLM\_VERSION** and whatever flags are needed by the target subroutine. One flag common to all the API calls is **WLM\_MUTE**, which is used to suppress the output of error messages from the WLM library to **STDERR**.

##### **confdir**

Specifies a null-terminated string. This field must be initialized with the name of the WLM configuration to which the target subroutine applies (when applicable, depending on the particular one).

Alternatively, this field can be set to a null string (\0). The null string indicates that the class addition or modification is to be applied only to the WLM kernel data, not to the class description files.

##### **class**

This field is a structure of type **struct class\_definition** that contains all the information pertaining to the superclass or subclass that is needed by the target subroutine. The fields in this structure can be initialized by a call to the **wlm\_init\_class\_definition** subroutine so that you only need to initialize the fields you wish to modify.

The main structure in the **wlm\_init\_class\_definition** subroutine is the class description, **struct class\_descr**, with the following fields:

**res** Specifies an array of type **struct wlm\_bounds** that contains the following fields for each resource type and for each total limit:

##### **iopriority**

Specifies the priority for I/O requests that are issued by the threads that are classified to the class. This priority is used to prioritize I/O buffers at the device level. Valid I/O priorities range from 0 through 15.

##### **min**

Specifies the minimum value, which is between 0 (the default) and 100 (unused for total limits).

##### **shares**

Specifies the shares number, which is a value between 1 and 65535. The value -1 (default) indicates that the given resource is not managed by WLM for the class (unused for total limits).

**wlmu** The union which contains the softmax (for all resources but total limits) and unit (for total limits only) fields:

**softmax**

Specifies the soft maximum limit, which is a value between 0 and 100 (default). The value must be greater than or equal to the value of the **min** field.

**unit** A string (3 characters maximum) that specifies the units that apply to the hardmax value for total limits. To let the units remain undefined, set the softmax field to **WLM\_UNIT\_UNDEF**. For **WLM\_RES\_TOTALCONNECT** and **WLM\_RES\_TOTALCPU**, the default unit is "s" (seconds) and other values are "m" (minutes), "h" (hours), "d" (days), and "w" (weeks). For **WLM\_RES\_TOTALDISKIO**, the default unit is "KB" (kilobytes) and other values are "MB" (megabytes), "GB" (gigabytes), "TB" (terabytes), "PB" (petabytes), "EB" (exabytes). The other total limits do not have units. For **WLM\_RES\_TOTALVMEM** and **WLM\_RES\_PROCVMEM**, set the unit to "MB", "GB", and "TB".

**hardmax**

For all resources but total limits. Specifies the hard maximum limit, which is a value between 0 and 100 (default). The value must be greater than or equal to each of the values of the **min** and **softmax** fields. For total limits, this parameter specifies their value, possibly along with the **unit** field. If the user does not specify a units value, the default units value is used. However, the user can specify a units value other than the default. The default (total limit unspecified) is **WLM\_HARDMAX\_UNDEF**.

The resource types are defined as **WLM\_RES\_CPU**, **WLM\_RES\_MEM**, **WLM\_RES\_BIO**, and total limits are defined as **WLM\_RES\_TOTALCPU** (total CPU time for a process), **WLM\_RES\_TOTALDISKIO** (total disk IOs for a process), **WLM\_RES\_TOTALCONNECT** (total Connection time), **WLM\_RES\_TOTALPROC** (total number of processes), **WLM\_RES\_TOTALTHRD** (total number of Threads), **WLM\_RES\_TOTALLOGIN** (total number of login sessions), **WLM\_RES\_TOTALVMEM** (total virtual memory usage for a class) and **WLM\_RES\_PROCVMEM** (total virtual memory usage for a process). Each value represents the index in the array of the element, corresponding to the type of resource or total limit.

**tier** Specifies the tier number for the class, which is a value between 0 (default) and 9

**inheritance**

Specifies how a new process is classified. A value of 0 (the default) indicates that a new process should be classified using the class assignment rules when calling the **exec** subroutine. A value of 1 indicates that the process inherits the class assignment from its parent process.

**localshm**

Indicates whether memory segments in this class remain local to the class (value 1) or if they go to the Shared class (value 0, the default), when accessed by a process belonging to another class.

**assign\_uid**

Specifies the user ID of the user allowed to manually assign processes to the class. The value must be a valid user ID.

The default when this attribute is not specified is that no user is authorized (WLM\_NOGUID).

**assign\_gid**

Specifies the group ID of the users allowed to manually assign processes to the class. The

value must be a valid group ID. The value must be a valid group ID. The default when this attribute is not specified is that no group is authorized (WLM\_NOGUID).

If both the **assign\_uid** and **assign\_gid** fields are the default value, only the root user can assign processes to the class.

#### **admin\_uid**

Specifies the user ID of the user allowed to administer the subclasses of the superclass (this attribute is valid only for superclasses)

#### **admin\_gid**

Specifies the group ID of the users allowed to administer the subclasses of the superclass (this attribute is valid only for superclasses)

If both the **admin\_uid** and **admin\_gid** fields are left to their default value (WLM\_NOGUID), only the root user can administer the subclasses of this superclass.

**name** Specifies the null-terminated full name of the class. The value must be in the format *super\_name* for a superclass and *super\_name.sub\_name* for a subclass. The superclass name and subclass name are limited to 16 characters each. This field has no default value.

In addition to the class description fields, the **class\_definition** structure adds two more fields:

#### **rset\_name**

Specifies a null-terminated character string containing the name of the resource set (partition) that the class is restricted to, when applicable. The default is that the class can access all the resources on the system.

#### **descr\_field**

Specifies a null-terminated character string containing the description text of the class. This field is optional and has no default.

#### **delshm**

Specifies whether to delete shared memory segments if the last process referencing the segment was killed due to a virtual memory limit. Valid values are "yes" and "no" (default).

#### **vmenforce**

Specifies whether the faulting process (value "proc", default) or all processes in a class (value "class") are killed when a virtual memory limit is reached.

### The **wlm\_assign** Structure

The **wlm\_assign** structure is used to manually assign processes or groups of processes to a specified superclass or subclass using the **wlm\_assign** subroutine. The **wlm\_assign** structure contains the following fields:

| Item                 | Description                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wa_versflags</b>  | Specifies the 4 high-order bits containing a version number. This version number is used by the API to maintain binary compatibility if the data structures are ever modified. The rest of the integer is used to pass flags to the subroutines when needed. |
|                      | This field should be initialized with the version number <b>WLM_VERSION</b> . The flag <b>WLM_MUTE</b> can be used to suppress the output of error messages from the WLM library on <b>stderr</b> .                                                          |
| <b>wa_pids</b>       | Specifies the address of an array containing the process identifiers (PIDs) of the processes to be manually assigned                                                                                                                                         |
| <b>wa_pid_count</b>  | Specifies the number of PIDs in the array above                                                                                                                                                                                                              |
| <b>wa_pgids</b>      | Specifies the address of an array containing the process group IDs (PGIDs) of the process groups to be manually assigned                                                                                                                                     |
| <b>wa_pgid_count</b> | Specifies the number of PGIDs in the array above                                                                                                                                                                                                             |
| <b>wa_classname</b>  | Specifies the full name of the superclass or the subclass of the class to which you want to manually assign processes                                                                                                                                        |

## The **wlm\_info** Structure

The **wlm\_info** structure is used to extract information about the current configuration parameters and current resource utilization of the active classes using the **wlm\_get\_info** subroutine. The **wlm\_info** structure contains the following fields:

| Item                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>i_descr</b>           | Specifies the class description of type <b>struct class_descr</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>i_regul</b>           | Specifies the per-resource-type array of structures, which are of the type <b>struct wlm_regul</b> , containing the following fields: <ul style="list-style-type: none"><li><b>consum</b> Specifies the resource consumption of the class. This value is expressed as a percentage of the total resource available.</li><li><b>total</b> Specifies the 64-bit number that represents the total amount of the resource consumed by the class since its creation (or since WLM was started). The value can be the number of milliseconds for CPU or the total number of 512-byte blocks for disk I/O. This field is left null (not significant) for memory.</li></ul> |
|                          | The indexes into the array of the various resources are defined as <b>WLM_RES_CPU</b> , <b>WLM_RES_MEM</b> and <b>WLM_RES_BIO</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>i_class_id</b>        | Specifies the class identifier (index of the class in the kernel <i>class_control_block</i> (ccb) table)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>i_cl_pri</b>          | Specifies the priority delta applied to the threads in the class for CPU regulation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>i_cl_inuse</b>        | Specifies the current number of processes in the class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>i_cl_nblogin</b>      | Specifies the current number of logins in the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>i_cl_nbthreads</b>    | Specifies the current number of threads in the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>i_cl_npaged</b>       | Specifies the number of memory pages currently allocated to the class                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>i_cl_nvpages</b>      | Specifies the total virtual memory usage for the class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>i_cl_nvpagehi</b>     | Specifies the virtual memory usage high water mark.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>i_cl_mem_hwm</b>      | Specifies the maximum number of resident memory pages this class had since its creation (memory high water mark)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>i_cl_change_level</b> | Specifies the number of increments each time a change in the current WLM configuration occurs. This field is used by the WLM monitoring tools.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## The **wlm\_bio\_class\_info\_t** and **wlm\_bio\_dev\_info\_t** Structures

Two structures can be used to get the I/O statistics using the **wlm\_get\_bio\_stats** subroutine, depending on whether the application wants per-class or per-device statistics.

The **wlm\_bio\_class\_info\_t** structure is used to gather I/O statistics per class and per device. The **wlm\_bio\_class\_info\_t** structure contains the following fields:

| Item             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>wbc_dev</b>   | Specifies the device identifier ( <i>dev_t</i> )                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>wbc_cid</b>   | Specifies the class identifier (index of the class in the kernel <i>class_control_block</i> table). Connecting the class ID and the class name can be performed by using the <b>wlm_get_info</b> subroutine. This subroutine returns the class name (in the <b>i_descr</b> field) and the class ID (in the <b>i_class_id</b> field) in the <b>wlm_info</b> structure.                                                                                                                                    |
| <b>wbc_regul</b> | Specifies a structure of type <b>struct wlm_regul</b> , which contains for the given class and device the following disk I/O statistics: <ul style="list-style-type: none"><li>• Resource utilization, which is expressed as a percentage of the total available throughput of the device (<b>consum</b>)</li><li>• Total number of 512-byte blocks read/written from and to the device by processes in the class since it was created, or since WLM started, whichever happened most recently</li></ul> |
| <b>wbc_delay</b> | Specifies in milliseconds the delay imposed on the I/Os of the processes in the class to the device. This delay is intended to limit utilization by class when it is consuming more than its entitled share.                                                                                                                                                                                                                                                                                             |

The **wlm\_bio\_dev\_info\_t** structure is used to gather the global statistics for a given device, taking into account all I/Os to and from the device by all the classes accessing the device. This structure contains the following fields:

| Item                    | Description                                                                                                                                                                                                                                                                                                                     |                                                                                  |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| <b>wbd_dev</b>          | Specifies the device identifier ( <i>dev_t</i> )                                                                                                                                                                                                                                                                                |                                                                                  |
| <b>wbd_active_cntrl</b> | Specifies the number of classes actively accessing the device                                                                                                                                                                                                                                                                   |                                                                                  |
| <b>wbd_in_queue</b>     | Specifies the number of requests in the device queue                                                                                                                                                                                                                                                                            |                                                                                  |
| <b>wbd_last</b>         | Specifies the device statistics for IOs that occurred during the last second.                                                                                                                                                                                                                                                   |                                                                                  |
|                         | This field is an array of integer values. The following symbolic values defined in the <b>wlm.h</b> file describe each index in the array:                                                                                                                                                                                      |                                                                                  |
|                         | <b>Index</b>                                                                                                                                                                                                                                                                                                                    | <b>Description</b>                                                               |
|                         | <b>WBS_OUT_RTHRPUT</b>                                                                                                                                                                                                                                                                                                          | Specifies the number of blocks actually read from the device (I/O completed)     |
|                         | <b>WBS_OUT_WTHRPUT</b>                                                                                                                                                                                                                                                                                                          | Specifies the number of blocks actually written to the device (I/O completed)    |
|                         | <b>WBS_IN_RTHRPUT</b>                                                                                                                                                                                                                                                                                                           | Specifies the requested number of blocks to be read from the device              |
|                         | <b>WBS_IN_WTHRPUT</b>                                                                                                                                                                                                                                                                                                           | Specifies the requested number of blocks to write to the device                  |
|                         | <b>WBS_REQUESTS</b>                                                                                                                                                                                                                                                                                                             | Specifies the number of read/write requests                                      |
|                         | <b>WBS_QUEUED</b>                                                                                                                                                                                                                                                                                                               | Specifies the number of requests queued                                          |
|                         | <b>WBS_STARVED</b>                                                                                                                                                                                                                                                                                                              | Specifies the number of requests starved (not serviced during the time interval) |
| <b>wbd_max</b>          | Contains the maximum values observed since the device was first used (after WLM was started) for all the entries of the array being described. For instance, the <b>wbd_max</b> field could contain the maximum number of blocks actually read from the device in one second since the device was first accessed.               |                                                                                  |
| <b>wbd_av</b>           | Contains the average values for all the entries in the array, such as the average number of requests in the device queue                                                                                                                                                                                                        |                                                                                  |
| <b>wbd_total</b>        | Specifies an array of 64-bit integers. This array is parallel to the arrays that, for every entry, contain the total of all the values measured every second since the device was first accessed. For instance, the value could represent the total number of blocks written to the device since the device was first accessed. |                                                                                  |

## The **wlm\_proc\_info** Structure

The **wlm\_proc\_info** structure is used to extract Workload Manager information about a process using the **wlm\_get\_procinfo** subroutine. The **totalconnecttime**, **termttime**, **totalcpuftime**, **totaldiskio** fields are only meaningful when the total process limits are enabled. The **wlm\_proc\_info** structure contains the following fields:

### **version**

This field should be initialized with **WLM\_VERSION**.

### **wlmflags**

Specifies some Workload Manager properties of the process, such as process with a rset **SWLMRSET** or as tag inheritance on fork **SWLMTAGINHERITFORK** or on exec **SWLMTAGINHERITEXEC**.

### **totalconnecttime**

Specifies the 64-bit number that represents the amount of time (in seconds) for which the login session has been active.

### **totalvmem**

Specifies the total amount of virtual memory used by the process in MBs.

**termtime**

Specifies the 64-bit number that represents the time (in seconds from 1970) when the process has been requested to terminate.

**totalcpu**

Specifies the 64-bit number that represents the amount of the CPU consumption (in microseconds) of the process.

**totaldiskio**

Specifies the 64-bit number that represents the amount of IO (in 512 bytes blocks) the process has run.

**classname**

Specifies the full name of the superclass or the subclass in which the process is classified.

**tag**      Specifies the character string associated with the process, if any ( see **wlm\_set\_tag** subroutine).

## Error Codes

The various WLM API subroutines may return one or several of the following error codes:

| Item                         | Description                                                              |
|------------------------------|--------------------------------------------------------------------------|
| <b>WLM_ALREADYINIT</b>       | A call to the <b>wlm_initialize</b> subroutine has already been made     |
| <b>WLM_ATERR</b>             | Attribute format error                                                   |
| <b>WLM_ATTGPATTR</b>         | Attribute Value Grouping not allowed in attributes                       |
| <b>WLM_ATTGPMISS</b>         | Cannot find Attribute Value Grouping definition                          |
| <b>WLM_ATTGPTOOLNG</b>       | Attribute Value Grouping too long                                        |
| <b>WLM_BADATTAPP</b>         | Could not access file (application field of attributes)                  |
| <b>WLM_BADATTGP</b>          | Bad format for Attribute Value Grouping                                  |
| <b>WLM_BADATTGRP</b>         | Unknown group in attributes                                              |
| <b>WLM_BADATTTAG</b>         | Invalid tag in attributes                                                |
| <b>WLM_BADATTTYP</b>         | Invalid process type in attributes                                       |
| <b>WLM_BADATTUSR</b>         | Unknown user in attributes                                               |
| <b>WLM_BADCLNAME</b>         | Bad class name                                                           |
| <b>WLM_BADCNAME</b>          | Class names must be alphanumeric                                         |
| <b>WLM_BADCONFIG</b>         | Invalid configuration name                                               |
| <b>WLM_BADDEFLIM</b>         | Default limits value that is specified in the limits file is invalid     |
| <b>WLM_BADDEFSHR</b>         | Default shares value that is specified in the shares file is invalid     |
| <b>WLM_BADFLAGS</b>          | Invalid flags value                                                      |
| <b>WLM_BADGID</b>            | The specified group ID is not valid on the system                        |
| <b>WLM_BADGRP</b>            | The specified group ID is not valid on the system                        |
| <b>WLM_BADINHER</b>          | The value specified for the class inheritance attribute is invalid       |
| <b>WLM_BADHARDTOTALLIMIT</b> | Invalid total limit (under minimum)                                      |
| <b>WLM_BADHMAX</b>           | The hard maximum limit values must be between 1 and 100                  |
| <b>WLM_BADLIMFMT</b>         | Value specified for minimum or maximum resource limit is invalid         |
| <b>WLM_BADLISATT</b>         | Invalid list in attributes                                               |
| <b>WLM_BADLIST</b>           | The process attribute list of an assignment rules is invalid             |
| <b>WLM_BADLOCALSHM</b>       | Bad <b>localshm</b> value                                                |
| <b>WLM_BADADMIN</b>          | Minimum resource limits values must be between 0 and 100                 |
| <b>WLM_BADRANGEF</b>         | Invalid format for a time range                                          |
| <b>WLM_BADRGRP</b>           | A group name specified in the <b>rules</b> file is invalid on the system |
| <b>WLM_BADRSET</b>           | Bad Rset attribute for a class                                           |
| <b>WLM_BADRUSR</b>           | A user name specified in the rules file is invalid on the system         |
| <b>WLM_BADSHARES</b>         | Shares values must be between 1 and 65535                                |
| <b>WLM_BADSMAX</b>           | The soft maximum limit values must be between 1 and 100                  |

| Item                    | Description                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>WLM_BADSHRFMT</b>    | Value specified for resource shares is invalid                                                                                    |
| <b>WLM_BADSUBLIMIT</b>  | A subclass total limit exceeds its superclass limit: The superclass limit will be used (warning)                                  |
| <b>WLM_BADSUPER</b>     | Bad superclass for subclass assignment                                                                                            |
| <b>WLM_BADTIER</b>      | Tier values must be between 0 and 9                                                                                               |
| <b>WLM_BADTAG</b>       | An invalid tag is specified in a rule                                                                                             |

| <b>WLM_SUMMIN</b>               | The sum that the minimum limits for a given resource and a given tier cannot exceed 100%                                                                                                                                                                                                                                         |
| <b>WLM_SYMLERR</b>              | An attempt to create a symbolic link did not succeed                                                                                                                                                                                                                                                                             |
| <b>WLM_TAGTOOLONG</b>           | Tag is too long                                                                                                                                                                                                                                                                                                                  |
| <b>WLM_TOOLONG</b>              | The specified class name is too long                                                                                                                                                                                                                                                                                             |
| <b>WLM_TOOLONGATT</b>           | Attribute list too long                                                                                                                                                                                                                                                                                                          |
| <b>WLM_TOOMANYATT</b>           | Too many items in attributes                                                                                                                                                                                                                                                                                                     |
| <b>WLM_TOOMANYPID</b>           | Process ID list too long                                                                                                                                                                                                                                                                                                         |
| <b>WLM_TOOSMALL</b>             | Output buffer too small                                                                                                                                                                                                                                                                                                          |
| <b>WLM_TOTALLIMITOUTOFRANGE</b> | Invalid total limit (outside allowed range)                                                                                                                                                                                                                                                                                      |
| <b>WLM_TRGAPS</b>               | Gaps between time ranges in a configuration set                                                                                                                                                                                                                                                                                  |
| <b>WLM_TRINDEFAULT</b>          | Time range not allowed in default stanza                                                                                                                                                                                                                                                                                         |
| <b>WLM_TROVERLAP</b>            | Time ranges overlap in a configuration set                                                                                                                                                                                                                                                                                       |
| <b>WLM_UNLOADERR</b>            | Cannot unload class                                                                                                                                                                                                                                                                                                              |
| <b>WLM_UNSUPP</b>               | Operation or flags value not supported                                                                                                                                                                                                                                                                                           |
| <b>WLM_WILDCRDATT</b>           | Wildcards not allowed in this attribute field                                                                                                                                                                                                                                                                                    |
| <b>WLM_WRITERR</b>              | An attempt to write to a file did not succeed                                                                                                                                                                                                                                                                                    |

## **x25sdefs.h File for X.25**

### **Purpose**

Contains the structures used by the X.25 application programming interface (API).

### **Description**

The `/usr/include/x25sdefs.h` file defines the following structures used by X.25 subroutines.

#### **Miscellaneous Structures**

| Item                             | Description                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>cb_link_name_struct</code> | Used to indicate the name of the X.25 port.                                                            |
| <code>cb_msg_struct</code>       | Used to indicate the type of message being received.                                                   |
| <code>ctr_array_struct</code>    | Used to store the counter values and identifiers for use with the <code>x25_ctr_wait</code> structure. |

#### **Structures Used to Establish Calls and Transfer Data**

| Item                             | Description                                                                                         |
|----------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>cb_call_struct</code>      | Used for calls made and accepted.                                                                   |
| <code>cb_data_struct</code>      | Used for data transferred during a call.                                                            |
| <code>cb_fac_struct</code>       | Used for information about optional facilities being used.                                          |
| <code>cb_pvc_alloc_struct</code> | Used to indicate the logical channel number and port assigned to a permanent virtual circuit (PVC). |

#### **Structures Used to Clear, Interrupt and Reset Calls**

| Item                            | Description                                               |
|---------------------------------|-----------------------------------------------------------|
| <code>cb_clear_struct</code>    | Used for calls being cleared.                             |
| <code>cb_int_data_struct</code> | Used for data sent or received in an interrupt packet.    |
| <code>cb_res_struct</code>      | Used for data sent or received in a reset-request packet. |

#### **Structures Used to Manage X.25 Communications**

| Item                                                             | Description                                   |
|------------------------------------------------------------------|-----------------------------------------------|
| <code>cb_circuit_info_struct</code>                              | Used for information about a virtual circuit. |
| <code>cb_link_stats_struct, x25_query_data, and x25_stats</code> | Used for statistics for an X.25 port.         |

For more information, see the individual descriptions of these structures.

## **cb\_call\_struct Structure for X.25**

### **Purpose**

Used by the `x25_call`, `x25_call_accept`, and `x25_receive` subroutines to pass the X.25 port name, called and calling addresses, facilities, and user data.

### **Syntax**

```
#define X25FLG_D_BIT 0x00000001
#define X25FLG_LINK_NAME 0x00000002
#define X25FLG_CALLED_ADDR 0x00000004
#define X25FLG_CALLING_ADDR 0x00000008
#define X25FLG_CB_FAC 0x00000010
#define X25FLG_USER_DATA 0x00000020
```

```

struct cb_call_struct
{
 unsigned long flags;
 char *link_name;
 char *called_addr;
 char *calling_addr;
 struct cb_fac_struct *cb_fac;
 int user_data_len;
 unsigned char *user_data;
} ;

```

## Flags

| Item                 | Description                                    |
|----------------------|------------------------------------------------|
| X25_FLG_D_BIT        | Indicates that the call uses D-bit procedures. |
| X25_FLG_LINK_NAME    | Indicates that the link_name field is used.    |
| X25_FLG_CALLED_ADDR  | Indicates that the called_addr field is used.  |
| X25_FLG_CALLING_ADDR | Indicates that the calling_addr field is used. |
| X25_FLG_CB_FAC       | Indicates that the cb_fac field is used.       |
| X25_FLG_USER_DATA    | Indicates that the user_data field is used.    |

## Fields

| Item          | Description                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| flags         | Notification to the API that the associated field has been used.                                                              |
| link_name     | Name of the X.25 port used for an incoming call.<br><b>Note:</b> This is set to null on received packets.                     |
| called_addr   | Pointer to the network user address (NUA) of the called data terminal equipment (DTE). The address is given in ASCIIZ format. |
| calling_addr  | Pointer to the NUA of the calling DTE. The address is given in ASCIIZ format.                                                 |
| cb_fac        | Pointer to the facilities information in the <b>cb_fac_struct</b> structure.                                                  |
| user_data_len | Field length for call user data (CUD).                                                                                        |
| user_data     | Pointer to call user data (CUD).                                                                                              |

## cb\_circuit\_info\_struct Structure for X.25

### Purpose

Used by the **x25\_circuit\_query** subroutine to return information about the circuit.

### Syntax

```

#define X25FLG_INCOMING_PACKET_SIZE
 0x00000001
#define X25FLG_OUTGOING_PACKET_SIZE
 0x00000002
#define X25FLG_INCOMING_THROUGHPUT_CLASS 0x00000004
#define X25FLG_OUTGOING_THROUGHPUT_CLASS 0x00000008
#define X25FLG_INCOMING_WINDOW_SIZE
 0x00000010
#define X25FLG_OUTGOING_WINDOW_SIZE
 0x00000020

```

```

struct cb_circuit_info_struct
{
 unsigned long flags;
 unsigned short lcn;
 unsigned int incoming_packet_size;
 unsigned int outgoing_packet_size;
 unsigned int incoming_throughput_class;
 unsigned int outgoing_throughput_class;
 unsigned int incoming_window_size;
 unsigned int outgoing_window_size;
} ;

```

## Flags

| Item                              | Description                                                 |
|-----------------------------------|-------------------------------------------------------------|
| X25_FLG_INCOMING_PACKET_SIZE      | Indicates that the incoming_packet_size field is used.      |
| X25_FLG_OUTGOING_PACKET_SIZE      | Indicates that the outgoing_packet_size field is used.      |
| X25_FLG_INCOMING_THROUGHPUT_CLASS | Indicates that the incoming_throughput_class field is used. |
| X25_FLG_OUTGOING_THROUGHPUT_CLASS | Indicates that the outgoing_throughput_class field is used. |
| X25_FLG_INCOMING_WINDOW_SIZE      | Indicates that the incoming_window_size field is used.      |
| X25_FLG_OUTGOING_WINDOW_SIZE      | Indicates that the outgoing_window_size field is used.      |

## Fields

| Item                      | Description                                                       |
|---------------------------|-------------------------------------------------------------------|
| flags                     | Notification to the API that the associated field has been used.  |
| lcn                       | Logical channel number.                                           |
| incoming_packet_size      | Actual size for incoming packets.                                 |
| outgoing_packet_size      | Actual size for outgoing packets.                                 |
| incoming_throughput_class | Throughput class for incoming calls.                              |
| outgoing_throughput_class | Throughput class for outgoing calls.                              |
| incoming_window_size      | Number of incoming packets that can be sent without confirmation. |
| outgoing_window_size      | Number of outgoing packets that can be sent without confirmation. |

## cb\_clear\_struct Structure for X.25

### Purpose

Used by the **x25\_call\_clear** and **x25\_receive** subroutines to pass the clear cause and diagnostic values, called and calling addresses, facilities information, and user data.

### Syntax

```

#define X25FLG_CAUSE ;0x00000001
#define X25FLG_DIAGNOSTIC 0x00000002
#define X25FLG_CALLED_ADDR 0x00000004
#define X25FLG_CALLING_ADDR 0x00000008
#define X25FLG_CB_FAC 0x00000010
#define X25FLG_USER_DATA 0x00000020

```

```

struct cb_clear_struct
{
 unsigned long flags;
 u_char cause;
 u_char diagnostic;

```

```

char *called_addr;
char *calling_addr;
struct cb_fac_struct *cb_fac;
int user_data_len;
u_char *user_data;
};

```

## Flags

| Item                 | Description                                    |
|----------------------|------------------------------------------------|
| X25_FLG_CAUSE        | Indicates that the cause field is used.        |
| X25_FLG_DIAGNOSTIC   | Indicates that the diagnostic field is used.   |
| X25_FLG_CALLED_ADDR  | Indicates that the called_addr field is used.  |
| X25_FLG_CALLING_ADDR | Indicates that the calling_addr field is used. |
| X25_FLG_CB_FAC       | Indicates that the cb_fac field is used.       |
| X25_FLG_USER_DATA    | Indicates that the user_data field is used.    |

## Fields

| Item          | Description                                                                                                                   |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| flags         | Notification to the API that the associated field has been used.                                                              |
| cause         | Cause value to be inserted in clear packet.                                                                                   |
| diagnostic    | Diagnostic reason to be inserted in packet.                                                                                   |
| called_addr   | Pointer to the network user address (NUA) of the called data terminal equipment (DTE). The address is given in ASCIIZ format. |
| calling_addr  | Pointer to the NUA of the calling DTE. The address is given in ASCIIZ format.                                                 |
| cb_fac        | Pointer to the facilities information in the <b>cb_fac_struct</b> structure.                                                  |
| user_data_len | Length of user-data field.                                                                                                    |
| user_data     | Pointer to user data. This can be used only if "fast select" has been requested in the call-request packet.                   |

## cb\_data\_struct Structure for X.25

### Purpose

Used by the **x25\_send** and **x25\_receive** subroutines to pass data control information.

### Syntax

```

#define X25FLG_D_BIT 0x00000001
#define X25FLG_Q_BIT 0x00000002
#define X25FLG_M_BIT 0x00000004
#define X25FLG_DATA 0x00000008

```

```

struct cb_data_struct
{
 unsigned long flags;
 int data_len;
 unsigned char *data;
} ;

```

## Flags

| Item         | Description                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| X25FLG_D_BIT | If the D-bit has been set in the call packet, and the value is not zero, the remote data terminal equipment (DTE) must acknowledge the packet. |
| X25FLG_Q_BIT | Sets the Q-bit in the packet. A nonzero value is converted to a single 1-bit in the packet.                                                    |
| X25FLG_M_BIT | Sets the M-bit in the packet. A nonzero value is converted to a single 1-bit in the packet.                                                    |
| X25_FLG_DATA | Indicates that the data field is used.                                                                                                         |

## Fields

| Item     | Description                                                      |
|----------|------------------------------------------------------------------|
| flags    | Notification to the API that the associated field has been used. |
| data_len | Length of data.                                                  |
| data     | Pointer to actual data.                                          |

## cb\_dev\_info\_struct Structure for X.25

### Purpose

Used by the `x25_device_query` subroutine to pass device information.

### Syntax

```
#define X25FLG_NUA 0x00000001
#define X25FLG_NO_OF_VCS 0x00000002
#define X25FLG_MAX_RX_PACKET_SIZE 0x00000004
#define X25FLG_MAX_TX_PACKET_SIZE 0x00000008
#define X25FLG_DEFAULT_SVC_RX_PACKET_SIZE 0x00000010
#define X25FLG_DEFAULT_SVC_TX_PACKET_SIZE 0x00000020
```

```
struct cb_dev_info_struct
{
 unsigned long flags;
 char *nua;
 unsigned int no_of_vcs;
 unsigned int max_rx_packet_size;
 unsigned int max_tx_packet_size;
 unsigned int default_svc_rx_packet_size;
 unsigned int default_svc_tx_packet_size;
};
```

### Flags

| Item                               | Description                                                  |
|------------------------------------|--------------------------------------------------------------|
| X25_FLG_NUA                        | Indicates that the nua field is used.                        |
| X25_FLG_NO_OF_VCS                  | Indicates that the no_of_vcs field is used.                  |
| X25_FLG_MAX_RX_PACKET_SIZE         | Indicates that the max_rx_packet_size field is used.         |
| X25_FLG_MAX_TX_PACKET_SIZE         | Indicates that the max_tx_packet_size field is used.         |
| X25_FLG_DEFAULT_SVC_RX_PACKET_SIZE | Indicates that the default_svc_rx_packet_size field is used. |
| X25_FLG_DEFAULT_SVC_TX_PACKET_SIZE | Indicates that the default_svc_tx_packet_size field is used. |

## Fields

| Item                       | Description                                                                         |
|----------------------------|-------------------------------------------------------------------------------------|
| flags                      | Notification to the API that the associated field has been used.                    |
| nua                        | Pointer to the network user address (NUA) recorded for the device in ASCIIZ format. |
| no_of_vcs                  | Number of permanent virtual circuits (PVCs) configured on this device.              |
| max_rx_packet_size         | Maximum receive packet size in bytes.                                               |
| max_tx_packet_size         | Maximum transmit packet size in bytes.                                              |
| default_svc_rx_packet_size | Default receive packet size in bytes.                                               |
| default_svc_tx_packet_size | Default transmit packet size in bytes.                                              |

```

**Note:** The example shows how to code the **cb\_fac\_struct** structure.

## Flags

| Item                    | Description                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------|
| X25FLG_RPOA             | Recognized private operating agency selection required ( rpoa_id).                                                           |
| X25FLG_PSIZ             | Packet size selection ( psiz_clg, psiz_cld).                                                                                 |
| X25FLG_WSIZ             | Window size selection ( wsiz_clg, wsiz_cld).                                                                                 |
| X25FLG_TCCLS            | Throughput class required ( tccls_clg, tccls_cld).                                                                           |
| X25FLG_REV_CHRG         | Reverse Charge required (no corresponding field).                                                                            |
| X25FLG_FASTSEL          | Fast select (no corresponding field).                                                                                        |
| X25FLG_FASTSEL_RSP      | Indicates whether a restricted response is required when the X25FLG_FASTSEL flag is also requested (no corresponding field). |
| X25FLG_CUG              | Closed user group selection required ( cug_id).                                                                              |
| X25FLG_OA_CUG           | Closed user group with outgoing access (basic format) selection required ( cug_id).                                          |
| X25FLG_BI_CUG           | Bilateral closed user group selection required ( cug_id).                                                                    |
| X25FLG_NUI_DATA         | Network user identification ( nui_data).                                                                                     |
| X25FLG_CI_SEG_CNT       | Charging information: segment count ( ci_seg_cnt).                                                                           |
| X25FLG_CI_MON_UNT       | Charging information: monetary unit ( ci_mon_unt).                                                                           |
| X25FLG_CI_CAL_DUR       | Charging information: call duration ( ci_cal_dur).                                                                           |
| X25FLG_CI_REQUEST       | Charging information is required (no corresponding field).                                                                   |
| X25FLG_CLAMN            | Called line address modified notification ( clamm).                                                                          |
| X25FLG_CALL_REDR        | Call redirection notification ( call_redr_addr, call_redr_reason).                                                           |
| X25FLG_TRAN_DEL         | Transit delay selection and notification ( tran_del).                                                                        |
| X25FLG_CALLING_ADDR_EXT | Calling address extension ( calling_addr_ext_use, calling_addr_ext).                                                         |

| Item                   | Description                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------|
| X25FLG_CALLED_ADDR_EXT | Called address extension ( <code>called_addr_ext_use</code> , <code>called_addr_ext</code> ).                         |
| X25FLG_MIN_TCCLS       | Quality of service negotiation: minimum throughput class ( <code>min_tccls_c1g</code> , <code>min_tccls_cld</code> ). |
| X25FLG_END_TO_END_DEL  | Quality of service negotiation: end-to-end transit delay ( <code>end_to_end_del</code> ).                             |
| X25FLG_EXP_DATA        | Expedited data negotiation (no corresponding field).                                                                  |
| X25FLG_FACEEXT         | Facilities extension: for all other facilities, including national options ( <code>fac_ext</code> ).                  |

## Fields

This section explains the meanings of structure fields but not the lengths associated with individual pointer fields.

| Item      | Description                                                                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags     | Notification to the API that the associated field has been used.                                                                                                                                                                                                                                                                                      |
| fac_ext   | Pointer to the facilities extension array (extra facility information provided by the user or network). No checking is made on the validity of this information. It allows extra facilities that the main <code>cb_fac</code> structure does not include. The elements of the <code>fac_ext</code> field are copied directly into the facility field. |
| psiz_c1g  | When the information is provided by the X.25 network or by the remote data terminal equipment (DTE), it is the responsibility of the application to interpret the field.                                                                                                                                                                              |
| psiz_cld  | Only elements up to the first non-X.25 facility are decoded by the API. Facility markers must be used in the <code>fac_ext</code> field if such facilities are required.                                                                                                                                                                              |
| wsiz_c1g  | Indicates the requested size for packets transmitted from the calling DTE. The following are supported values:                                                                                                                                                                                                                                        |
| wsiz_cld  | <ul style="list-style-type: none"> <li>• 0x04 = 16 octets</li> <li>• 0x05 = 32 octets</li> <li>• 0x06 = 64 octets</li> <li>• 0x07 = 128 octets</li> <li>• 0x08 = 256 octets</li> <li>• 0x09 = 512 octets</li> <li>• 0x0A = 1024 octets</li> <li>• 0x0B = 2048 octets</li> <li>• 0x0C = 4096 octets</li> <li>• ...</li> </ul>                          |
| tccls_c1g | Requested size for packets transmitted from the called DTE. Supported values are the same as for the <code>psiz_c1g</code> field.                                                                                                                                                                                                                     |
| tccls_cld | Requested size for the window for packets transmitted by the calling DTE. Values range from 0x01 to 0x07 inclusive.                                                                                                                                                                                                                                   |
| rpoa_id   | Requested size for the window for packets to be transmitted by the called DTE. Values range from 0x01 to 0x07 inclusive.                                                                                                                                                                                                                              |
| cug_id    | Throughput class requested for data to be sent by the calling DTE. The following are supported values:                                                                                                                                                                                                                                                |
| nui_data  | <ul style="list-style-type: none"> <li>• 0x07 = 1200 bits per second</li> <li>• 0x08 = 2400 bits per second</li> <li>• 0x09 = 4800 bits per second</li> <li>• 0x0A = 9600 bits per second</li> <li>• 0x0B = 19,200 bits per second</li> <li>• 0x0C = 48,000 bits per second</li> </ul>                                                                |
| tccls_cld | Throughput class request for data sent from the called DTE. Supported values are the same as for the <code>tccls_c1g</code> field.                                                                                                                                                                                                                    |
| tccls_cld | Indicates the requested RPOA (Requested Private Operating Agency) transit network. Each element of the array is an RPOA identifier.                                                                                                                                                                                                                   |
| cug_id    | Indicates the identifier of a closed user group (CUG). Used for all modes of CUG and also for bilateral CUGs.                                                                                                                                                                                                                                         |
| nui_data  | Network user identification data in a format specified by the network administrator.                                                                                                                                                                                                                                                                  |

| Item                 | Description                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ci_seg_cnt           | Charging information: segment count data.                                                                                                                                                                                                                                                                                                                                                     |
| ci_mon_unt           | Charging information: monetary unit data.                                                                                                                                                                                                                                                                                                                                                     |
| ci_cal_dur           | Charging information: call-duration data.                                                                                                                                                                                                                                                                                                                                                     |
| call_redr_addr       | The address to which the call has been redirected. The address is stored in ASCIIZ format.                                                                                                                                                                                                                                                                                                    |
| call_redr_reason     | Contains reason for call redirection.                                                                                                                                                                                                                                                                                                                                                         |
| tran_del             | Transit delay in milliseconds.                                                                                                                                                                                                                                                                                                                                                                |
| calling_addr_ext_use | Indicates the use of the calling address extension.                                                                                                                                                                                                                                                                                                                                           |
| calling_addr_ext     | Up to 40 digits containing the calling address extension. The address extension is stored in ASCIIZ format. The following are values for the extended calling and called address flags:<br>#DEFINE X25_FAC_ADDR_EXT_USE_ENTIRE_OSI_NSAP(0)<br>#DEFINE X25_FAC_ADDR_EXT_USE_PARTIAL_OSI_NSAP(1)<br>#DEFINE X25_FAC_ADDR_EXT_USE_NON_OSI(2)                                                     |
| called_addr_ext_use  | Indicates the use of the called address extension.                                                                                                                                                                                                                                                                                                                                            |
| called_addr_ext      | Up to 40 digits containing the called address extension. The address extension is stored in ASCIIZ format. See the calling_addr_ext field for values.                                                                                                                                                                                                                                         |
| clann                | Called line address modified notification. Contains the reason for redirection.                                                                                                                                                                                                                                                                                                               |
| min_tcls_clg         | Throughput class requested for data to be sent by the calling DTE. The following are supported values: <ul style="list-style-type: none"> <li>• 0x07 = 1200 bits per second</li> <li>• 0x08 = 2400 bits per second</li> <li>• 0x09 = 4800 bits per second</li> <li>• 0x0A = 9600 bits per second</li> <li>• 0x0B = 19,200 bits per second</li> <li>• 0x0C = 48,000 bits per second</li> </ul> |
| min_tcls_cld         | Throughput class request for data sent from the called DTE. Supported values are the same as for the min_tcls_clg field.                                                                                                                                                                                                                                                                      |
| end_to_end_del       | Specifies cumulative requested end-to-end and maximum-acceptable transit delays. Requested end-to-end and maximum-acceptable values are optional.                                                                                                                                                                                                                                             |

## Examples

This is a simple example of the use of the **cb\_fac\_struct** structure:

```
/*
```

```

 &
 */
struct cb_call_struct cb_call;
struct cb_fac_struct fac_struct;
u_char facilities_extension[10],facilities_extension[8];
ushort rpoa_ext_id[3] = {7,8,9};
char extended_calling_addr[] = "1234567890"; /* extension */
/* Initialize flags

 */
fac_struct.flags = 0;
/* Use of RPOAE

 */
fac_struct.rpoa_id = rpoa_ext_id;
fac_struct.rpoa_id_len = 3;
fac_struct.flags |= X25FLG_RPOA;
/* Use of extended addressing

```

```

 */
fac_struct.calling_addr_ext = extended_calling_addr;
fac_struct.flags |= X25FLG_CALLING_ADDR_EXT;
/* Use of extended facilities

 /*
facilities_extension[0] = 0x00; /*
start of a Facility Marker */
facilities_extension[1] = 0x00; /*
non_X25 facility supported */

 /* by
calling DTE
*/
facilities_extension[2] = 0x55; /*
a facility
*/
facilities_extension[3] = 0x66; /*
a facility

*/facilities_extension[4] = 0x00;
/* start of a Facility Marker */
facilities_extension[5] = 0xFF; /*
non_X25 facility supported */

 /* by
called DTE
*/
facilities_extension[6] = 0x88; /*
a facility
*/
facilities_extension[7] = 0x99; /*
a facility

*/
strcpy(fac_struct.fac_ext, facilities_extension);
fac_struct.fac_ext_len = 8;
fac_struct.flags |= X25FLG_FACEXT;
/*****************/
/* In this example a cb_call structure
is initialized
*/
/* with a cb_fac structure.

 */
/*****************/
cb_call.cb_fac = &fac_struct;
cb_call.flags = X25FLG_CB_FAC;

```

## **cb\_int\_data\_struct Structure for X.25**

### **Purpose**

Used by the **x25\_interrupt** and **x25\_receive** subroutines to pass the interrupt data.

## Syntax

```
#define X25FLG_INT_DATA 0x00000001
struct cb_int_struct
{
 unsigned long flags ;
 unsigned char int_data_len;
 unsigned char *int_data;
} ;
```

## Flags

| Item            | Description                                                                          |
|-----------------|--------------------------------------------------------------------------------------|
| X25FLG_INT_DATA | A non-zero value indicates the presence of data in the <b>cb_int_data</b> structure. |

## Fields

| Item         | Description                                                      |
|--------------|------------------------------------------------------------------|
| flags        | Notification to the API that the associated field has been used. |
| int_data_len | Length of data in the <b>cb_int_data</b> structure.              |
| int_data     | Interrupt data.                                                  |

## **cb\_link\_name\_struct Structure for X.25** **Purpose**

Used by the **X25\_init**, **x25\_link\_connect**, **x25\_link\_disconnect**, **x25\_link\_monitor**, **x25\_device\_query**, and **x25\_term** subroutines to pass the name of the X.25 port.

## Syntax

```
#define X25FLG_LINK_NAME 0x00000002
```

```
struct cb_link_name_struct
{
 unsigned long flags;
 char *link_name;
};
```

## Flags

| Item              | Description                                        |
|-------------------|----------------------------------------------------|
| X25_FLG_LINK_NAME | Indicates that the <b>link_name</b> field is used. |

## Fields

| Item      | Description                                                      |
|-----------|------------------------------------------------------------------|
| flags     | Notification to the API that the associated field has been used. |
| link_name | Name of the X.25 port.                                           |

## **cb\_link\_stats\_struct, x25\_query\_data, or x25\_stats Structure for X.25** **cb\_link\_stats\_struct Structure**

Used by the **x25\_link\_statistics** subroutine to pass statistics about an X.25 port.

```

#define X25FLG_NO_OF_VCS 0x00000008
#define X25FLG_LINK_STATS 0x00000020

struct cb_link_stats_struct
{
 unsigned long flags;
 unsigned int no_of_vcs;
 struct x25_query_data x25_stats;
} ;

```

## Flags

| Item               | Description                                           |
|--------------------|-------------------------------------------------------|
| X25_FLG_NO_OF_VCS  | Indicates that the no_of_vcs field is used.           |
| X25_FLG_LINK_STATS | Indicates that the x25_stats structure is being used. |

## Fields

| Item      | Description                                                               |
|-----------|---------------------------------------------------------------------------|
| flags     | Notification to the API that the associated field has been used           |
| no_of_vcs | Number of virtual circuits currently in use for the X.25 port specified   |
| x25_stats | Pointer to an x25_query_data structure containing CIO and X.25 statistics |

## x25\_query\_data Structure

The **x25\_query\_data** structure is returned from the **CIO\_QUERY** ioctl operation. It includes two structures: the **cio\_stats** structure containing standard statistics values found in the **sys/comio.h** file, and the **x25\_stats** structure containing specific X.25 statistics.

```

struct x25_query_data
{
 struct cio_stats cc;
 struct x25_stats ds;
};

```

## x25\_stats Structure

The **x25\_stats** structure contains specific X.25 statistics.

**Note:** Flags are not used with this structure.

```

typedef unsigned short x25_stat_value_t;
struct x25_stats
{

```

## Fields

| <b>Item</b>            | <b>Description</b>                                                                |
|------------------------|-----------------------------------------------------------------------------------|
| ignored_f_tx           | Number of transmitted frames that have been ignored instead of being transmitted. |
| rr_f_tx                | Number of RR (receive ready) frames transmitted.                                  |
| rnr_f_tx               | Number of RNR (receive not ready) frames transmitted.                             |
| rej_f_tx               | Number of REJ (reject) frames transmitted.                                        |
| info_f_tx              | Number of INFO (information) frames transmitted.                                  |
| sabm_f_tx              | Number of SABM (set asynchronous balanced mode) frames transmitted.               |
| sarm_dm_f_tx           | Number of SARM/DM frames transmitted.                                             |
| disc_f_tx              | Number of DISC (disconnect) frames transmitted.                                   |
| ua_f_tx                | Number of UA (unnumbered acknowledgment) frames transmitted.                      |
| frmrf_tx               | Number of FRMR (frame received) frames transmitted.                               |
| bad_nr_f_tx            | Number of frames transmitted with a bad N(R) value.                               |
| unknown_f_tx           | Number of unknown frames transmitted.                                             |
| xid_f_tx               | Number of XID frames transmitted.                                                 |
| bad_length_f_tx        | Number of bad length frames transmitted.                                          |
| t1_expirations         | Number of times the T1 timer has timed out.                                       |
| lvl2_connects          | Number of times the frame level has been connected.                               |
| lvl2_disconnects       | Number of times the frame level has been disconnected.                            |
| carrier_loss           | Number of times the carrier signal was lost.                                      |
| connect_time           | Number of seconds that the link has been connected.                               |
| t4_expirations         | Number of times the T4 timer has timed out.                                       |
| t4_n2_expirations      | Number of times the T4 timer has timed out N2 times.                              |
| ignored_f_rx           | Number of received frames that have been ignored instead of being received.       |
| rr_f_rx                | Number of RR frames received.                                                     |
| rnr_f_rx               | Number of RNR frames received.                                                    |
| rej_f_rx               | Number of REJ frames received.                                                    |
| info_f_rx              | Number of INFO frames received.                                                   |
| sabm_f_rx              | Number of SABM frames received.                                                   |
| sarm_dm_f_rx           | Number of SARM/DM frames received.                                                |
| disc_f_rx              | Number of DISC frames received.                                                   |
| ua_f_rx                | Number of UA frames received.                                                     |
| frmrf_rx               | Number of FRMR frames received.                                                   |
| bad_nr_f_rx            | Number of frames received with a bad N(R) value.                                  |
| unknown_f_rx           | Number of unknown frames received.                                                |
| xid_f_rx               | Number of XID frames received.                                                    |
| bad_length_f_rx        | Number of bad length frames received.                                             |
| data_p_tx              | Number of data packets transmitted.                                               |
| rr_p_tx                | Number of RR packets transmitted.                                                 |
| rnr_p_tx               | Number of RNR packets transmitted.                                                |
| interrupt_p_tx         | Number of interrupt packets transmitted.                                          |
| interrupt_confirm_p_tx | Number of interrupt-confirmation packets transmitted.                             |

| <b>Item</b>               | <b>Description</b>                                       |
|---------------------------|----------------------------------------------------------|
| call-request_p_tx         | Number of call-request packets transmitted.              |
| call-accept_p_tx          | Number of call-accept packets transmitted.               |
| clear_request_p_tx        | Number of clear-request packets transmitted.             |
| clear_confirm_p_tx        | Number of clear-confirm packets transmitted.             |
| reset_request_p_tx        | Number of reset-request packets transmitted.             |

## **cb\_msg\_struct Structure for X.25 Purpose**

Used by the `x25_receive` and `x25_call_clear` subroutines to pass the contents of a received packet to an application.

### **Syntax**

```
struct cb_msg_struct
{
 int msg_type;
 union
 {
 struct cb_call_struct *cb_call;
 struct cb_data_struct *cb_data;
 struct cb_clear_struct *cb_clear;
 struct cb_res_struct *cb_res;
 struct cb_int_struct *int_data;
 } msg_point;
};
```

### **Fields**

| Item                                    | Description                                                                                                                                                                                              |
|-----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>msg_type</code>                   | Type of message being returned, as follows:                                                                                                                                                              |
| <code>X25_CALL_CONNECTED</code>         | Call connected: The <code>cb_call</code> field points to the <code>cb_call_struct</code> structure.                                                                                                      |
| <code>X25_INCOMING_CALL</code>          | Incoming call: The <code>cb_call</code> field points to the <code>cb_call_struct</code> structure.                                                                                                       |
| <code>X25_DATA</code>                   | Data: The <code>cb_data</code> field points to the <code>cb_data_struct</code> structure.                                                                                                                |
| <code>X25_DATA_ACK</code>               | Data acknowledgment: no buffer.                                                                                                                                                                          |
| <code>X25_INTERRUPT</code>              | Interrupt: The <code>int_data</code> field points to the <code>cb_int_data_struct</code> structure.                                                                                                      |
| <code>X25_INTERRUPT_CONFIRMATION</code> | Confirmation of a previously issued interrupt request: no data is returned.                                                                                                                              |
| <code>X25_CLEAR_INDICATION</code>       | Indication that call has been cleared.                                                                                                                                                                   |
| <code>X25_CLEAR_CONFIRM</code>          | Confirmation that the call has been cleared. The <code>cb_clear</code> field points to the <code>cb_clear_struct</code> structure. (This should only be received on a <code>x25_call_clear</code> call.) |
| <code>X25_RESET_INDICATION</code>       | Reset indication: The <code>cb_res</code> field points to the <code>cb_res_struct</code> structure.                                                                                                      |
| <code>X25_RESET_CONFIRM</code>          | Reset confirmation: no data is returned.                                                                                                                                                                 |
| <code>X25_UNKNOWN_PACKET</code>         | Allow for packets in future CCITT releases. These packets can be safely ignored by the application.                                                                                                      |
| <code>cb_call</code>                    | Pointer to the call structure, <code>cb_call_struct</code> .                                                                                                                                             |
| <code>cb_data</code>                    | Pointer to the data structure, <code>cb_data_struct</code> .                                                                                                                                             |
| <code>cb_clear</code>                   | Pointer to the clear structure, <code>cb_clear_struct</code> .                                                                                                                                           |
| <code>cb_res</code>                     | Pointer to the reset structure, <code>cb_res_struct</code> .                                                                                                                                             |
| <code>int_data</code>                   | Pointer to the interrupt data structure, <code>cb_int_data_struct</code> .                                                                                                                               |

## **cb\_pvc\_alloc\_struct Structure for X.25 Purpose**

Used by the `x25_pvc_alloc` subroutine to pass the name of the X.25 port and the logical channel number.

### **Syntax**

```
#define X25FLG_LINK_NAME 0x00000002
#define X25FLG_LCN 0x00000004

struct cb_pvc_alloc_struct
{
 unsigned long flags;
 char *link_name;
 unsigned int lcn;
};
```

### **Flags**

| Item              | Description                                 |
|-------------------|---------------------------------------------|
| X25_FLG_LCN       | Indicates that the lcn field is used.       |
| X25_FLG_LINK_NAME | Indicates that the link_name field is used. |

### **Fields**

| Item      | Description                                                                                |
|-----------|--------------------------------------------------------------------------------------------|
| flags     | Notification to the API that the associated field has been used.                           |
| link_name | The name of the X.25 port.                                                                 |
| lcn       | Logical channel number of the permanent virtual circuit (PVC) to be allocated to the call. |

## **cb\_res\_struct Structure for X.25 Purpose**

Used by the `x25_reset` and `x25_receive` subroutines to pass the reset cause and diagnostic codes.

### **Syntax**

```
#define X25FLG_CAUSE 0x00000001
#define X25FLG_DIAGNOSTIC 0x00000002

struct cb_res_struct
{
 unsigned long flags;
 unsigned char cause;
 unsigned char diagnostic;
};
```

### **Flags**

| Item               | Description                                  |
|--------------------|----------------------------------------------|
| X25_FLG_CAUSE      | Indicates that the cause field is used.      |
| X25_FLG_DIAGNOSTIC | Indicates that the diagnostic field is used. |

## Fields

Structure field definitions are as follows:

| Element    | Description                                                                            |
|------------|----------------------------------------------------------------------------------------|
| flags      | Notification to the API that the associated field has been used.                       |
| cause      | Cause value of either 0 or in the range 0x80-0xFF, to be inserted in the reset packet. |
| diagnostic | Diagnostic reason to be inserted in the packet. The CCITT default value is 0.          |

## ctr\_array\_struct Structure for X.25

### Purpose

Used by the `x25_ctr_wait` subroutine to pass the counter identifier and a value to be exceeded.

### Syntax

```
#define X25FLG_CTR_ID 0x00000001
#define X25FLG_CTR_VALUE 0x00000002

struct ctr_array_struct
{
 unsigned long flags;
 int ctr_id;
 int ctr_value;
} ;
```

## Flags

| Item              | Description                                              |
|-------------------|----------------------------------------------------------|
| X25_FLG_CTR_ID    | Indicates that the <code>ctr_id</code> field is used.    |
| X25_FLG_CTR_VALUE | Indicates that the <code>ctr_value</code> field is used. |

## Fields

| Item      | Description                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags     | Notification to the API that the associated field has been used.                                                                                                                                                                                                                                |
| ctr_id    | Counter identifier.                                                                                                                                                                                                                                                                             |
| ctr_value | Value to be exceeded by the counter specified by the counter identifier. The counter is incremented each time a message for the associated call or PVC arrives. When the number of messages exceeds the value, the <code>x25_ctr_wait</code> subroutine returns control to the calling program. |

## Directories

Information that is needed by several different files or functions is collected into a header file. A header file contains C-language definitions and structures. Centralizing information into a header file facilitates the creation and update of programs. Because `#include` statements are used to insert header files into a C-language program, header files are often referred to as include files.

Because directories often contain information that should not be available to all users of the system, directory access can be protected. See File ownership and user groups in *Operating system and device management* for more information.

## Understanding Types of Directories

Directories can be defined by the system or the system administrator, or you can define your own directories. The system-defined directories contain specific kinds of system files, such as commands. At the top of the file system hierarchy is the system-defined root directory. The root directory is represented by a / (slash) and usually contains the following standard system-related directories:

| Item       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| /admin     | Filesystem created by the root user at system installation. This filesystem is used for root privilege process for temporary space for security. The /admin filesystem is defined on the implemented /dev/hd1ladmin system logical volume. The discretionary access control mode of the /admin filesystem is 755. Only the root user can write the /admin directory.                                                                                                                                                                                                                                                                                    |
| /admin/tmp | Root directory used by several root privilege processes to write temporary files. A root privileged process is a process that is started by a command with the <b>setuid</b> or <b>setgid</b> parameter, by a binary, or by a script with root system ownership. The discretionary access control mode of the /admin/tmp directory is 755. Only root users can write the /admin/tmp directory.                                                                                                                                                                                                                                                          |
| /bin       | Symbolic link to the /usr/bin directory. In prior UNIX file systems, the /bin directory contained user commands that now reside in /usr/bin in the new file structure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| /dev       | Contains device nodes for special files for local devices. The /dev directory contains special files for tape drives, printers, disk partitions, and terminals.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| /etc       | Contains configuration files that vary for each machine. Examples include: <ul style="list-style-type: none"><li>• /etc/hosts</li><li>• /etc/passwd</li></ul> The /etc directory contains the files generally used in system administration. Most of the commands that used to reside in the /etc directory now reside in the /usr/sbin directory. However, for compatibility, it contains symbolic links to the new locations of some executable files. Examples include: <ul style="list-style-type: none"><li>• /etc/chown is a symbolic link to the /usr/bin/chown.</li><li>• /etc/exportvg is a symbolic link to the /usr/sbin/exportvg.</li></ul> |
| /export    | Contains the directories and files on a server that are for remote clients.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| /home      | Serves as a mount point for a file system containing user home directories. The /home file system contains per-user files and directories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| /lib       | In a standalone machine, a separate local file system is mounted over the /home directory. In a network, a server might contain user files that should be accessible from several machines. In this case, the server's copy of the /home directory is remotely mounted onto a local /home file system.                                                                                                                                                                                                                                                                                                                                                  |
| /proc/sys  | Symbolic link to the /usr/lib directory, which contains architecture-independent libraries with names in the form lib*.a.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| /sbin      | Files in /proc/sys are used internally for kernel tuning and statistics gathering.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| /tmp       | Contains files needed to boot the machine and mount the /usr file system. Most of the commands used during booting come from the boot image's RAM disk file system; therefore, very few commands reside in the /sbin directory.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| /u         | Serves as a mount point for a file system that contains system-generated temporary files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| /usr       | Symbolic link to the /home directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| /var       | Serves as a mount point for files that vary on each machine. The /var file system is configured as a file system since the files it contains tend to grow. For example, it is a symbolic link to the /usr/tmp directory, which contains temporary work files.                                                                                                                                                                                                                                                                                                                                                                                           |

Some directories, such as your login or home directory (**\$HOME**), are defined and customized by the system administrator. When you log in to the operating system, the login directory is the current directory. If you change directories using the **cd** command without specifying a directory name, the login directory becomes the current directory.

Directories

## /etc/locks Directory

### Purpose

Contains lock files that prevent multiple uses of communications devices and multiple calls to remote systems.

### Description

The **/etc/locks** directory contains files that lock communications devices and remote systems so that another user cannot access them when they are already in use. Other programs check the **/etc/locks** directory for lock files before attempting to use a particular device or call a specific system.

A lock file is a file placed in the **/etc/locks** directory when a program uses a communications device or contacts a remote system. The file contains the process ID number (PID) of the process that creates it.

The Basic Networking Utilities (BNU) program and other communications programs create a device lock file whenever a connection to a remote system, established over the specified device, is actually in use. The full path name of a device lock file is:

**/etc/locks/DeviceName**

where the *DeviceName* extension is the name of a device, such as *tty3*.

When the BNU **uucico** daemon, **cu** command, or **tip** command places a call to a remote system, it puts a system lock file in the **/etc/locks** directory. The full path name of a system lock file is:

**/etc/locks/SystemName**

where the *SystemName* extension is the name of a remote system, such as *hera*. The system lock file prevents more than one connection at a time to the same remote system.

Under normal circumstances, the communications software automatically removes the lock file when the user or program ends the connection to a remote system. However, if a process executing on the specified device or system does not complete its run (for example, if the computer crashes), the lock file remains in the **/etc/locks** directory either until the file is removed manually or until the system is restarted after a shutdown.

## /usr/lib/hcon Directory

### Purpose

Contains files used by the Host Connection Program (HCON).

## Description

The **/usr/lib/hcon** directory contains files used by the Host Connection Program (HCON). It contains color and keyboard definition files, terminal definition files, HCON API subdirectories, AUTOLOG example scripts, configuration data base files, and the command to start the HCON subsystem.

### Color and Keyboard Definition Files

The following files contain data used to define and customize the HCON color and keyboard definition tables:

| File             | Contents                                 |
|------------------|------------------------------------------|
| <b>e789_ctbl</b> | Default binary color-definition table    |
| <b>e789_ktbl</b> | Default binary keyboard-definition table |

The color and keyboard definition tables in the **/usr/lib/hcon** directory specify defaults for use by HCON emulator sessions. The **hconutil** command allows users to customize color and keyboard definition tables.

### Terminal Definition Files

The HCON installation process creates a **terminfo** subdirectory in the **/usr/lib/hcon** directory. The **/usr/lib/hcon/terminfo** directory contains terminal definition files that are specific to HCON. When HCON is installed, the **terminfo** directory contains the following files:

| File             | Contents                                                                        |
|------------------|---------------------------------------------------------------------------------|
| <b>ibm.ti.H</b>  | Terminal definitions for LFT, 5081, 3151, 3161, 3162, 3163, and 3164 terminals. |
| <b>dec.ti.H</b>  | Terminal definitions for DEC VT100 and DEC VT220 terminals.                     |
| <b>wyse.ti.H</b> | Terminal definition for the WYSE WY-50 and WYSE WY-60 terminals.                |

The **terminfo** binary files for HCON terminal definitions are in subdirectories of the **/usr/lib/hcon/terminfo** directory. Each subdirectory is named with the first letter of the terminal name. When HCON is installed, the **terminfo** directory contains the following subdirectories:

| Subdirectory | Contents                                                                            |
|--------------|-------------------------------------------------------------------------------------|
| <b>a</b>     | Binary terminal definition file for running within the operating system windows     |
| <b>h</b>     | Binary terminal definition files for color and monochrome LFT                       |
| <b>i</b>     | Binary terminal definition files for the 5081, 3151, 3161, 3162, and 3163 terminals |
| <b>j</b>     | Binary terminal definition file for use with operating system windows               |
| <b>v</b>     | Binary terminal definition files for the DEC VT100 and DEC VT220 terminals          |
| <b>w</b>     | Binary terminal definition files for the WYSE WY-50 and WYSE WY-60 terminals        |

In addition to those delivered with HCON, the **/usr/lib/hcon/terminfo** subdirectory can contain customized terminal definitions.

### HCON API Subdirectories

The HCON installation process creates two subdirectories in the **/usr/lib/hcon** directory that contain files used by the HCON API:

| Directory  | Contents                                                                                           |
|------------|----------------------------------------------------------------------------------------------------|
| <b>mvs</b> | API programs to use in interfacing to MVS/TSO host systems, including the <b>instalapi</b> program |
| <b>vm</b>  | API programs to use in interfacing to VM/CMS host systems, including the <b>instalapi</b> program  |

## AUTOLOG Example Scripts

The **/usr/lib/hcon** directory contains several example files for the AUTOLOG facility. These files are:

| File           | Contents                                                    |
|----------------|-------------------------------------------------------------|
| <b>logform</b> | Example <b>genprof</b> form for creating AUTOLOG procedures |
| <b>SYStso</b>  | Example AUTOLOG script for MVS/TSO host                     |
| <b>SYSvm1</b>  | Example AUTOLOG script for VM/CMS host                      |
| <b>SYSvm2</b>  | Example AUTOLOG script for VM/CMS host                      |

## Configuration Data Base Files

The following files contain HCON configuration information. This information is used by HCON programs, by the Object Data Manager (ODM), and by the HCON configuration commands, which are called by the System Management Interface Tool (SMIT).

| File               | Contents                      |
|--------------------|-------------------------------|
| <b>sysdflts</b>    | HCON database system defaults |
| <b>sysdflts.vc</b> | HCON database system defaults |
| <b>users</b>       | HCON users database           |

## Command to Start the HCON Subsystem

The **sthcondmn** command is used to start the **hcondmn** subsystem after HCON has been installed.

## Files

| Item                                    | Description                    |
|-----------------------------------------|--------------------------------|
| <b>/usr/lib/hcon/terminfo</b> directory | Contains terminal definitions. |

## /var/spool/mqueue Directory for Mail

### Purpose

Contains the **log** file and temporary files associated with the messages in the mail queue.

### Description

The **/var/spool/mqueue** directory contains temporary files associated with the messages in the mail queue and may contain the **log** file. For further information, see the **syslogd** daemon.

Temporary files have names that include the mail queue ID (*MQID*) of the message for which the file was created:

| Item                | Description                 |
|---------------------|-----------------------------|
| <code>dfMQID</code> | Data file                   |
| <code>lfMQID</code> | Lock file                   |
| <code>nfMQID</code> | Backup file                 |
| <code>qfMQID</code> | Queue control file          |
| <code>tfMQID</code> | Temporary control file      |
| <code>xfMQID</code> | Transcript file for session |

## /var/spool/uucp Directory for BNU Purpose

Stores Basic Networking Utilities (BNU) log, administrative, command, data, and execute files in multiple subdirectories.

### Description

The `/var/spool/uucp` directory, also known as the BNU spooling directory, is the parent directory for multiple work directories created by the Basic Networking Utilities (BNU) program to facilitate file transfers among systems.

The following directories are subdirectories of the `/var/spool/uucp` directory:

| Item                    | Description                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>.Admin</code>     | Contains four administrative files, including: <ul style="list-style-type: none"> <li>• <code>audit</code></li> <li>• <code>Foreign</code></li> <li>• <code>errors</code></li> <li>• <code>xferstats</code></li> </ul>                                      |
| <code>.Corrupt</code>   | Contains copies of files that could not be processed by the BNU program.                                                                                                                                                                                    |
| <code>.Log</code>       | Contains log files for the <code>uucico</code> and <code>uuxqt</code> daemons.                                                                                                                                                                              |
| <code>.Old</code>       | Contains old log files for the <code>uucico</code> and <code>uuxqt</code> daemons.                                                                                                                                                                          |
| <code>.Status</code>    | Records the last time the <code>uucico</code> daemon tried to contact remote systems.                                                                                                                                                                       |
| <code>.Workspace</code> | Holds temporary files that the file transport programs use internally.                                                                                                                                                                                      |
| <code>.Xqtdir</code>    | Contains execute files with lists of commands that remote systems can run.                                                                                                                                                                                  |
| <code>SystemName</code> | Contains files used by file transport programs, including: <ul style="list-style-type: none"> <li>• Command (<code>C.*</code>)</li> <li>• Data (<code>D.*</code>)</li> <li>• Execute (<code>X.*</code>)</li> <li>• Temporary (<code>TM.*</code>)</li> </ul> |

## /var/spool/uucp/.Admin Directory for BNU Purpose

Contains administrative files used by BNU.

## Description

The **/var/spool/uucp/.Admin** directory contains administrative files used by the Basic Networking Utilities (BNU) program to facilitate remote communications among systems. The **.Admin** directory contains the following files:

| File      | Description                                            |
|-----------|--------------------------------------------------------|
| audit     | Contains debug messages from the <b>uucico</b> daemon. |
| Foreign   | Logs contact attempts from unknown remote systems.     |
| errors    | Records <b>uucico</b> daemon errors.                   |
| xferstats | Records the status of file transfers.                  |

## /var/spool/uucp/.Corrupt Directory for BNU Purpose

Contains copies of files that could not be processed.

## Description

The **/var/spool/uucp/.Corrupt** directory contains copies of files that could not be processed by the Basic Networking Utilities (BNU) program. For example, if a file is not in the correct form for transfer, the BNU program places a copy of that file in the **.Corrupt** directory for later handling. This directory is rarely used.

The files in the **.Corrupt** directory are removed periodically by the **uudemon.cleanu** command, a shell procedure.

### Related information:

[uudemon.cleanu command](#)  
[Understanding the BNU File and Directory Structure](#)

## /var/spool/uucp/.Log Directories for BNU Purpose

Contain the BNU program log files.

## Description

The **/var/spool/uucp/.Log** directories contain Basic Networking Utilities (BNU) program log files. The BNU program normally places status information about each transaction in the appropriate log file each time you use the networking utilities facility.

All transactions of the **uucico** and **uuxqt** daemons as well as the **uux** and **uucp** commands are logged in files named for the remote system concerned. Each file is stored in a subdirectory of the **/var/spool/uucp/.Log** directory, named for the daemon or command involved. Each subdirectory contains a separate file for each remote system contacted. Thus, the log files are named according to one of the following formats:

*/var/spool/uucp/.Log/DaemonName/SystemName*

OR

*/var/spool/uucp/.Log/CommandName/SystemName*

All activities of the **uucp** command are logged in the *SystemName* file in the */var/spool/uucp/.Log/uucp* directory. All activities of the **uux** command are logged in the *SystemName* file in the */var/spool/uucp/.Log/uux* directory.

The **uucp** and **uuto** commands call the **uucico** daemon. The **uucico** daemon activities for a particular remote system are logged in the *SystemName* file in the */var/spool/uucp/.Log/uucico* directory on the local system.

The **uux** command calls the **uuxqt** daemon. The **uuxqt** daemon activities for a particular remote system are logged in the *SystemName* file in the */var/spool/uucp/.Log/uuxqt* directory on the local system.

When more than one BNU process is running, however, the system cannot access the standard log file, so it places the status information in a file with a **.Log** prefix. The file covers that single transaction.

The BNU program can automatically append the temporary log files to a primary log file. This is called *compacting the log files* and is handled by the **uudemon.cleanu** command, a shell procedure. The procedure combines the log files of the activities of the **uucico** and **uuxqt** daemons on a particular system and stores the files in the */var/spool/uucp/.Old* directory.

The default is for the **uudemon.cleanu** command to save log files that are two days old. This default can be changed by modifying the appropriate line in the shell procedure. If storage space is a problem on a particular system, reduce the number of days that the files are kept in their individual log files.

The **uulog** command can be used to view the BNU program log files.

#### Related information:

[cron command](#)

[BNU log files](#)

[Understanding the BNU File and Directory Structure](#)

## **/var/spool/uucp/.Old Directory for BNU Purpose**

Contains the combined BNU program log files.

#### Description

The */var/spool/uucp/.Old* directory contains the combined Basic Networking Utilities (BNU) program log files.

The BNU program creates log files of the activities of the **uucico** and **uuxqt** daemons in the */var/spool/uucp/.Log* directory. The log files are compacted by the **/usr/sbin/uucp/uudemon.cleanu** command, a shell procedure, which combines the files and stores them in the *.Old* directory.

By default, the **uudemon.cleanu** command removes log files after two weeks. The length of time log files are kept can be changed to suit the needs of an individual system.

The log files can be viewed using the **uulog** command.

## Files

| Item                           | Description                     |
|--------------------------------|---------------------------------|

## /var/spool/uucp/.Status Directory for BNU

### Purpose

Contains information about the status of the BNU program contacts with remote systems.

### Description

The **/var/spool/uucp/.Status** directory contains information about the status of the Basic Networking Utilities (BNU) program contacts with remote systems.

For each remote system contacted, the BNU program creates a file in the **.Status** directory called *SystemName*, which is named for the remote system being contacted. In the **.Status/SystemName** file, the BNU program stores:

- Time of the last call in seconds
- Status of the last call
- Number of retries
- Retry time, in seconds, of the next call

**Note:** The times given in the **.Status/SystemName** file are expressed as seconds elapsed since midnight of January 1, 1970 (the output of a **time** subroutine). Thus, the retry time is in the form of the number of seconds that must have expired since midnight of January 1, 1970, before the system can retry. To make this entry in the **.Status/SystemName** file, BNU performs a **time** subroutine, adds 600 seconds, and places the resulting number of seconds in the file.

If the last call was unsuccessful, the **uucico** daemon will wait until the time specified by the retry time before attempting to contact the system again. The retry time in the **.Status/SystemName** file can be overridden using the **-r** flag of the **uutry** or **Uutry** command.

## /var/spool/uucp/SystemName Directories for BNU

### Purpose

Contain queued requests for file transfers and command executions on remote systems.

## Description

The `/var/spool/uucp/SystemName` directories are the Basic Networking Utilities (BNU) spooling directories on the local system. The BNU program creates a *SystemName* directory for each system listed in the `/etc/uucp/Systems` file, including the local system.

Each *SystemName* directory contains queued requests issued by local users for file transfers to remote systems and for command executions on remote systems.

The BNU program uses several types of administrative files to transfer data between systems. The files are stored in the *SystemName* directories:

| Item                          | Description                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>command (C.*)</code>    | Contain directions for the <code>uucico</code> daemon concerning file transfers.                                                                                                            |
| <code>data (D.*)</code>       | Contain data to be sent to remote systems by the <code>uucico</code> daemon.                                                                                                                |
| <code>execute (X.*)</code>    | Contain instructions for running commands on remote systems.                                                                                                                                |
| <code>temporary (TM.*)</code> | Contain data files after their transfer to the remote system until the BNU program can deliver them to their final destinations (usually the <code>/var/spool/uucppublic</code> directory). |

## /var/spool/uucppublic Directory for BNU Purpose

Stores BNU files until they can be delivered.

### Description

The **/var/spool/uucppublic** directory is the public directory for the Basic Networking Utilities (BNU) facility. One of these directories exists on every system connected by the BNU utilities.

When a user transfers a file to a remote system or issues a request to execute a command on another system, the files generated by these BNU commands are stored in the public directory on the designated system until the destination directory is ready to receive them. (A user can also specify a destination other than the public directory when issuing the **uucp**, **uuto**, or **uux** command.) The transferred files remain in the **uucppublic** directory until they are removed manually or automatically.

**Note:** The files are stored in the **uucppublic/SystemName** subdirectory of the **uucppublic** directory, where the *SystemName* directory is named for the remote system where the files originated.

All spooling directories are dynamic, including the public directory. Depending on the size of your installation and the number of files sent to the local **/var/spool/uucppublic** directory by users on remote systems, this directory can become quite large.

The **uudemon.cleanu** command, a shell procedure, cleans up all the BNU spooling directories, including the public directories. Use the **uucleanup** command with the **-sSystemName** flag to clean up the directories on a specific system.
